Among all this mess of cords was found the median nerve, very nearly severed, the laceration extending transversely through the nerve toward its posterior aspect, leaving but a strip of the nerve-sheath and probably a few fibers. There was a gap of about an inch, with no sign of bulbous swelling, yet covered over by a layer of fibrous elements. The sheath of the nerve was slit and sutured after careful approximation of cut edges. The laceration of the nerve was at a point near where the trunk divides into its separate individual branches, that is, central to such division. This nerve caused some confusion for a time, and even my colleagues, E. J. Senn, C. Wagner and J. Printy, who were present, guessed as to its identity. It was of remarkably large size, like one of the tendons, and for a long time was taken as one. To remove all doubt, the first incision was continued up the arm for a distance of two inches.

Fig. 1.—Appearance of field of operation before surgical repair commenced. The large arteries are not shown, for they were drawn to one side. (*a*) Deep flexor tendons (central ends). (*b*) Bands of connective tissue at ends of tendons. (*c*) Long flexor of thumb. (*d*) Lacerated portion of median nerve. (*e*) Superficial flexor tendons (central ends). (*f*) Loose connective tissue over pronator quadratus. (*g*) Retracted distal ends of superficial and deep flexor tendons (pulled up). (*h*) Line showing position of receipt of injury. (*i*) Actual position of retracted distal ends of flexor tendons (under skin).

The position and relations then observed established its anatomic identity. The next step was the suturing of the severed tendons in such a way that practical use could be had of the fingers affected. It was indeed very remarkable that there should be so much contracture of the parts involved in the lesion, so soon after the injury.

The modus operandi in suturing together the muscular elements was instituted as follows: The distal end of the deep flexor tendon to the index finger was pulled up out of its position and sutured into the long flexor tendon of the thumb (a slit being made in the tendon of the latter) at a point opposite the upper end of the groove below the thenar eminence, as far as the tendon could be drawn, the hand and all of the fingers being flexed as much as possible.

The distal ends of the deep flexor tendons of the middle and ring fingers were drawn up and sutured into the deep flexor tendon of the little finger (a slit being made in the tendon of the latter). The proximal ends of the deep flexor tendons were left in position, in which they were held by fibrous bands.

Now, the proximal ends of the group of tendons of the flexor sublimus digitorum were drawn down and sutured to the distal ends of the corresponding tendons, a few stitches including the upper margin of the ulnar portion of the divided palmar fascia. This latter fastening stood out very prominently, like a bridge, although the hand was flexed to its limit.

It was intended at first to splice the muscle above, in order to afford better and clearer approximation of the severed tendons, but it was held impracticable under the circumstances, the limit of physiologic stretching being at a minimum.

Both my colleagues and myself thought of other methods of tendon suture, such as Czerny, split tendon, Anderson's method, kangaroo tendon and bridgework of stout catgut sutures, but because of the great degree of separation of the tendon ends, it was considered best to abandon these methods.

After all these structures were secured and placed in position the contiguous edges of the palmar fascia were firmly

Fig. 2.—Appearance of field of operation after surgical repair was instituted. The large arteries are not shown, for they were drawn to one side. (*a*) Central ends of deep flexor tendons. (*b*) Flexor longus pollicis. (*c*) Median nerve repaired. (*d*) Distal end of deep flexos tendon to index finger. (*e*) Superficial flexor tendons. (*f*) Deep flexor tendon to little finger. (*g*) Distal ends of deep flexor tendons to ring and little fingers respectively. (*h*) Palmar fascia to which superficial tendons were sutured.

brought together and sutured. Then the separated edges of the superficial fascia and skin were approximated and stout anchoring catgut sutures inserted at regular intervals, more of them being employed in the region of the angle formed by the flexion of the hand on the forearm, and then a continuous horse-hair suture of the skin from end to end of the incision.

Little hemorrhage was encountered. Over the wrist-joint, at about the lower ends of the ulna and radius, buttonholes were made in reflected skin and gauze drains inserted. Antiseptic dressings were applied with the forearm fixed at right angles to the arm and against the body. A plaster-of-paris splint was applied from the axilla nearly down to the tips of the fingers. The fingers were snugly flexed on a small roller bandage.

The accompanying illustrations will show the picture of the open field of operation before and after suturing of the tendons and repair of the median nerve. (Figs. 1 and 2.)

Thirteen days after the operation dressings were removed for inspection; there was no swelling or discoloration. The wound had healed by primary intention. Sensation and nutrition in the fingers and hand were normal. At no time after the operation did the boy have any abnormal temperature, or cardiac disturbance. Fifteen days after the operation the boy was taken home and further examination made at convenient intervals.

After the first five weeks had passed we instituted massage, passive and active motion. After the second week, and thereafter, active motion of the fingers affected, elicited steady, slow and gradual improvement of flexion.

September 3 photographs were taken of the parts involved in this case. Three positions are represented, showing (Fig. 3) the relations of the fingers to one another, giving a view of the scar, indicating the line of incision employed in the operation, and the bulging at the wrist due to the tension of the flexor tendons. Figure 4 shows the relations of the hand, wrist, forearm and arm, as secured by means of the plaster-of-paris splint. Figure 5 shows the extremity elevated and the anterior surface exposed.

Figure 3.

For a few weeks at this period there was a good deal of stiffness around the wrist-joint and hand, but this gradually diminished under vigorous treatment with massage, baths and electricity. After the third month the boy was given daily exercise in the way of carrying weights, such as a bucket of water, which he faithfully performed.

At about the middle of October the hand could be fully extended and the fingers nearly so. He had the ability to double up his fist. There was, of course, a well-marked and long cicatrix along the middle of the anterior surface of the forearm and wrist, but by massage we restored the cutaneous portion to as near a perfect condition as could be gained.

Dec. 20, 1901, nearly full extension of fingers was observed. There was complete flexion of fingers. He can not flex the thumb or little finger without causing flexion of the index, middle and ring fingers, thus demonstrating the results of suturing of tendons, as instituted at the time of operation.

The boy has suffered no pain at any time, the only reminiscence of any severe condition to the member at present is the long cicatrix and vicarious movements of the fingers. Now he uses (at the time of this writing) both hands alike in his manual work, no difficulty being shown even when attempting

Figure 4.

to write, or play on the piano. Each finger can be voluntarily put into action, no stiffness being perceptible.

Figure 5.

Thus is shown the necessity of early tendon suture, with slow and careful inspection and operative progression.

SATURDAY, FEBRUARY 21, 1903.

AN EPIDEMIC OF TYPHOID-LIKE DISEASE.

The application of bacteriologic methods to the routine clinical study of typhoid fever led to the demonstration of cases of typhoid-like diseases, or paratyphoid, associated with bacilli that differ from the typical typhoid bacillus in essential biologic characteristics yet clearly belong in the same general group. These bacilli are called paratyphoid or paracolon bacilli. The number of isolated cases of paratyphoid has increased rapidly. Wherever modern bacteriologic methods have been used in the examination of typhoid fever, cases of paratyphoid have been disclosed sooner or later. Judging from current reports in medical journals and before medical societies paratyphoid would seem to be coextensive with typhoid fever. Wherever the latter occurs in endemic form occasional cases of the former may be confidently regarded as demonstrable sooner or later if examinations for that purpose are instituted.

It is most interesting, however, to learn that recently epidemic paratyphoid has been recognized in which all of the cases have been shown to be caused by paratyphoid organisms. The reports of such an epidemic come from Germany.[1] The disease developed in a regiment of soldiers, but all the facts are not at hand as yet concerning the mode of infection and spread of the disease. The cases—some 38 in all—received prompt and careful study. In not a single one of them did the examinations disclose typical typhoid bacilli in the feces, urine or roseolæ; on the other hand, a typhoid-like organism was recovered from some of these sources in nearly all of the cases. This bacillus is much like the typhoid bacillus in shape and size, but it differs in many cultural characteristics, and it is far more pathogenic for animals. The bacillus was agglutinated by the serum of patients in high dilutions, but not at all by the serum of normal persons. A peculiar, at first sight somewhat confusing feature, was the agglutination even in high dilutions by the serum of the patients of the true typhoid bacillus. The agglutinins for the true typhoid bacillus disappeared much earlier than those for the typhoid-like organism. The latter agglutinins also grew in strength as the disease progressed and persisted in the blood far into convalescence. Animal experiments brought out the very interesting fact that immunization with the typhoid-like bacillus gave rise to agglutinins for both these bacilli; here again the agglutination of the typhoid-like organism was the stronger. For the reason that a duplex agglutinative property was produced by the injection of the typhoid-like bacillus the authors feel that there was no absolute necessity for assuming the existence in these cases of a mixed infection. It would have been of great interest to have the results of systematic blood cultures in an endemic like this. Apparently the authors were satisfied with the demonstration of the peculiar organisms in the roseolæ of a certain number of cases. It is not at all unlikely from what we now know in regard to typhoid bacillemia that in this series a bacillemia also existed, and the demonstration of the bacilli in the blood of a number of cases would have strengthened materially the etiologic relationship of the organism.

This being the first epidemic of typhoid-like disease recognized as such the practitioner naturally will be interested in the clinical features. In the main the clinical picture was that of typhoid fever, but certain peculiarities were noted. In many cases the beginning of the disease was rather abrupt and the termination equally sudden. The fever was not very high as a rule and of rather short duration. On the whole the symptoms were not severe. There were no fatal cases.

The authors suggest the propriety of designating the diseases caused by bacilli related to but not identical with the typhoid bacillus as "typhoid" diseases. This usage of the word "typhoid" is, of course, not at all objectionable from the purely German standpoint, but it is sure eventually to cause confusion among English-speaking physicians. We would urge on our German confrères the advisability of abandoning at once the use of the word "typhoid" in the sense suggested and to substitute the word paratyphoid (in German "paratyphus"). This would not cause any confusion in the minds of English readers of German articles and books. Finally, it is proper to say that this study of a paratyphoid endemic will serve to emphasize the importance of the paratyphoid infections and it also indicates that with time as observations multiply it is probable that certain clinical peculiarities of paratyphoid will be established.

THE SIGNIFICANCE OF LEUCOCYTOSIS IN SURGICAL DIAGNOSIS.

Surgeons have lately been devoting considerable attention to the diagnostic value of the white blood count, specially in acute abdominal conditions, and with very contradictory results, as shown by their conclusions. Some have expressed the belief that leucocytosis as an aid to the surgeon in diagnosis is far from having positive value; that the facts are too much at variance and too contradictory to be relied on; and that, as at present developed in the hands of the average surgeon if constantly acted on, do great harm. Others believe that there is considerable diagnostic value in the leucocyte count in doubtful cases and always have an estimation made in such cases.

Kühn[1] of Rostock University, in a paper on the diagnostic value of leucocytosis, gives tabulated results of his estimations in a series of operative cases, and concludes that the leucocyte count is a diagnostic aid of great importance, with special value in acute suppurative processes. Positive results were obtained only in cases in which pus was in the process of developing; with localization and abscess formation the leucocytosis usually gradually disappears. Only high counts have special value, the lower counts giving very little information. In chronic suppurative processes leucocytosis may be entirely absent.

These opinions are, we believe, in accord with the expressions of those who have had most experience in the study of the blood in acute abdominal conditions. Many criticisms have come from those who have not had personal experience in the study of the blood and whose criticisms for this reason have been in some degree unjust and possibly have had a harmful tendency. It should be recognized with the leucocyte count as with other clinical methods that it is but one of many aids in reaching a diagnosis, and when carefully made and correctly interpreted it may be of considerable value. We can not determine the exact condition of the kidneys or bladder by examination of the urine; neither is it usually possible to determine the exact condition of intrathoracic organs by physical examination of the chest, but by using these methods we often obtain most valuable information. The condition of the pulse and temperature gives another example of this kind. We presume there are few surgeons at the present time who neglect to take the temperature of their patients at frequent intervals in acute cases, yet every surgeon recognizes that in many acute intra-abdominal inflammatory conditions there may be only a moderate elevation of temperature, and in brain abscess there is frequently a subnormal temperature, yet all surgeons recognize that, as a rule, elevation of temperature is an important sign of inflammation. While the clinical thermometer is not a positively reliable guide to the patient's condition, no one would justify neglect of its use.

In the same way the leucocyte count alone, while not giving positive indication to operate or not to operate, is of too much value in determining the condition of the patient to be neglected. The criticisms of those unfamiliar with such modern clinical methods are less likely to do serious harm than some champions of clinical laboratory methods seem inclined to believe, for comparatively few older practitioners have been trained in such methods or are likely to take them up, while the younger generation who have such training appreciate the value of new methods as well as their limitations and will scarcely be likely to be influenced by opinions which conflict with their own experience and that of competent authorities. Those who depreciate the value of modern scientific methods not only tend to hinder progress, but also put themselves in a bad light in the eyes of those who have studied modern methods and appreciate them.

THE DECREASING BIRTH-RATE SCARE.

The alleged decrease in the birth rate of the American-born population in this country is the subject of a recent article in one of our contemporaries.[1] It seems to suggest that we shall soon be following the same course toward natural extinction that had been alarming France. The subject has excited considerable popular attention, and a previous utterance on the subject from the chief magistrate of our country has been brought into prominence. This is a subject which has been mentioned, not once but frequently, in past numbers of The Journal. It is not the United States alone, but many other civilized countries that give evidence of declining birth rates.

The facts, however, as to our own country are too deficient to enable us to lay down a rule, or to say that the condition is one that need excite natural alarm. The registration district in this country is comparatively small and includes only a few of our older states where, from emigration and other circumstances, the birth rate might naturally be expected to be on the decline. In most of the country the returns of births are absolutely unreliable, and any jeremiads on the subject will lack grounds to make them actual indications of the true condition of things. Even in the New England states, where the decline is alleged to have been greatest, there has, in the last decade, been a slight increase. The fact is that a falling birth rate is a natural index of moderate prosperity and thrift. It is only when it falls beyond a certain point that it becomes actually threatening. It is a biologic fact that high living and over-nutrition diminish reproductiveness, and we notice this in the human species as well as in the lower animals, but in man reproductiveness is still further affected by economic and social conditions. The decrease is relative, not actual, for even in France the birth rate exceeds the death rate.

We still have in this country a very extensive proletariat and as population becomes more dense and the conditions of life harder it will increase. The probabilities are that within the next hundred years the increase of the birth rate among the poor will be more alarming than its decrease among the well-to-do. It is none the less advisable to check the evil, however, so far as we see it exists. It would be a good thing if the best American stock would keep up its numbers. We trust it will, and we do not believe that there is any reliable evidence that it is not now doing so. The descendants of the Puritans have spread themselves over the whole territory of the United States and have leavened the rest of the population. Like the Norman blood in England, the Puritan stock will never die out, though the aristocracy, so to speak, may constantly require accessions from below.

1. N. Y. Med. Record, Jan. 31.

CHAUVINISM IN MEDICINE.

A bill before the Michigan legislature proposes to make Canadian physicians who wish to register and who do not possess American qualifications take one year of study in the Michigan medical schools. Canada has a similar practice; in some of the provinces no one not possessing Canadian or British qualifications can register without taking a course in one of the provincial schools. We have already commented on this fact in connection with Dr. Osler's lecture on Chauvinism in medicine, as a brilliant illustration of what he was warning against, in the very community in which he spoke. We can not say that we entirely like this sort of retaliatory reciprocity, and should regret to see Michigan adopt the Canadian policy. Let the Canadian applicant for practice go through a thorough examination, let him bring evidence of character and standing, but, if these are satisfactory, it is entirely superfluous to make him go through a local school for the sake of fees or to discourage his incoming. We need not be narrow because others are.

THE DIPLOMA VS. EXAMINATION.

Under the general system of medical examinations as a prerequisite to the granting of license to practice medicine it is inevitable that the few states that still require only a diploma will be the dumping-ground for incompetents and quacks. A diploma means only that its holder has satisfied the faculty of his college, that he has passed its requirements, and this does not by any means always imply that he is fitted to take charge of the lives and health of the public. Moreover, there are diplomas and diplomas, and there is no absolute surety of their value except in a very discriminating and limited list of recognized institutions. The acceptance of a mere diploma is, in fact, a surrender of the right of the state to fully protect its citizens. It is for these reasons that we regret to see that in the amended law now before the Colorado legislature this feature is retained and examination only required for non-graduates or those from unrecognized institutions. We can not say what were all the circumstances that induced its retention, but it is regrettable that it was thought advisable. The quality of the medical profession in Colorado will not be improved by lax requirements of professional qualifications. There are now hardly more than half a dozen states and territories that admit to practice on diplomas. It will be unfortunate for Colorado if it is to remain among them.

PHYSICIANS' AND LAWYERS' INCOMES IN BERLIN.

Medical practice in Berlin apparently does not pay so well as the profession of law, according to the *Berliner Lokal-Anzeiger* of January 29. In it an interesting comparison of the income of physicians and lawyers is made, greatly to the disadvantage of the former. In the district there were last year 3,639 physicians as against 3,458 in the preceding and 3,376 in 1900. In 144, 3.95 per cent., there was absolutely no income whatever. In 977, or 26.85 per cent., there was a total income of $225 to $750; 640, or 17.56 per cent., had from $750 to $1,250; 1,033, or 17.8 per cent., had from $1,250 to $2,625; 649, or 17.8 per cent., had from $2,625 to $12,500, and 49, or 1.4 per cent., had from $12,500 to $55,000 income. It would seem, therefore, that nearly one-half of the Berlin physicians, or more particularly, about 44 per cent., had an income of $1,200 or less. According to the figures for legal practice furnished by authorities, which, on the other hand, only included the net income, 10 per cent. of the lawyers received under $750; 12 per cent. had from $750 to $1,250; 50 per cent. from $1,250 to $2,500; 12 per cent. from $2,500 to $3,750; 8 per cent. from $3,750 to $5,000, and 8 per cent. over $5,000. There are, therefore, just twice as many physicians as lawyers with an income of $3,000 or less, and yet the medical profession increases in numbers. There must be something in scientific medicine that is attractive to the ingenuous youthful mind, altogether aside from mercenary considerations.

FOOLISH LEGISLATION.

There seems to be a tendency on the part of some state legislators to propose very unjust and ridiculous laws, some of which have a medical bearing. Among them are the anti-kissing laws which have been introduced in several state legislatures within the last two or three years, and such acts as the Wemple bill, now before the New York legislature. The latter is, we think, only a repetition of what was proposed one or two years ago to prevent any operation on a female except in the presence of a near friend. The author of this bill, as the *New York Tribune* says, possesses a singular lack of familiarity with the requisites of success in difficult surgery. Still another that perhaps might be placed in this class is the so-called "health day" proposition in the Utah legislature, which, it is said, is proposed to be also introduced in Illinois. This provides that on a certain day of the year general house cleaning and disinfection shall be practiced, and that it shall be a misdemeanor to fail to clean up. This would turn everybody out of doors for the time being. We might reproduce the Jewish feast of the tabernacles and go into camps. Speaking seriously, however desirable a general house cleaning might be, such a law as this would be almost impossible to enforce and would cause serious inconvenience, and in most communities, we think, would soon pass into "innocuous desuetude." It would require inspection to enforce the law, and this could be better done with a wider range of action; a good sanitary inspection with power to enforce orders, which is perfectly practicable, would be all that is required and far better than the naming of a special day for universal house cleaning and general tearing up of things. We can, therefore, class this among the fake legislations, or at least among the ill-judged propositions that we trust will not be made laws. However good the idea the difficulties would defeat its usefulness.

THE CALIFORNIA PLAGUE SITUATION.

The plague situation in California appears to be clearing up. The new governor is not following in the footsteps of his predecessor, but, as was to be expected from his antecedents, is in favor of active measures, rather than the ostrich policy of denial, to secure to the state a clean bill of health. As one evidence of

this he has withdrawn his predecessor's nominees for the State Board of Health, and it is to be hoped that he will so thoroughly reorganize that body that it may command the confidence of the people. The commercial organizations of San Francisco have also spoken, demanding coöperation of the health boards of the city and state with the Marine Hospital authorities in the stamping out of the infection, and pledge their support to the work. Until very recently, however, the mayor of San Francisco had not publicly changed his attitude of denial of the existence of plague in that city, although he had privately admitted it. He has, however, by force of circumstances, had to learn the lesson that in this, as in other matters, "honesty is the best policy," and we need not anticipate any active opposition from that quarter when the national and state authorities have fairly taken the matter in hand. The risk of a serious outbreak of plague among the San Francisco Chinese, which has been an impending possibility for the last three years, will now be appreciably lessened with a state health board working in harmony with the federal health authorities. The whole history of the California plague is a moral lesson of the impolicy of allowing an unprincipled commercialism to override scientific facts in sanitation. The plague of misrepresentation which has been infecting San Francisco was worse than the bubonic plague, and some of the San Francisco press have hardly yet sufficiently recovered from its effects.

THE ETIOLOGY OF CANCER.

Notwithstanding all the work done in cancer etiology, one of the best European authorities, Professor Lubarsch of Posen, in Germany, a man who is thoroughly familiar with the whole subject and who has evidently spared no pains to get at all the recent publications, gives it as his conclusive opinion that we are as yet not in a position to say anything definite of the cause of malignant disease. He says[1] that while it is clear that all forms of malignant neoplasms resemble each other so much as to make it sure that if one is due to parasite the others are also, we have as yet no sure evidence that a parasite is the actual causative agent. On the other hand, Professor Lubarsch considers that there are groups of true neoplasms histologically different from carcinomata which yet share with them the destructive properties of giving metastases and causing cachexia, with regard to which, however, a parasitic cause is out of the question. Even in the epithelial group of the carcinomata there are many special classes of tumors whose peculiarities would be very difficult to explain on this score. He adds that even if the etiologic rôle of parasites in the causation of a malignant disease is to be accepted, there are other causes that must be considered to have at least equal value. Chronic irritation seems, for instance, especially for many epithelial carcinomata, to be an almost indispensable predisposing condition. Without the preparation of soil, developed by frequently repeated irritation, the epitheliomata fail to make their appearance. The presence of embryonal or postembryonal cellular material included in certain parts of the tissue, with a special tendency to take on an excessive formative disposition, seems to be another predisposing cause without which many neoplasms would not develop. In any theory of cancer etiology, then, these conditions and their effects will have to be taken into account quite as well as any supposed influence of parasites. As a matter of fact, it is not definitely settled yet whether cancer may not be originally a lack of vitality in the connective tissue rather than a surplus of vitality in the parenchymatous tissues. The normal state of the cellular tissues consists of an equilibrium of cellular forces so established that the constituents of the supporting tissues and the more specialized cells of the various organs have just enough resistive vitality to keep from interfering with the growth of one another, or, on the other hand, of permitting overgrowth on the part of their neighbors. Weigert and Roux have insisted that neoplastic formation is usually due, not to an acquired *nisus formativus*—a special new tendency to overgrowth—but to the disappearance of the resistive factors which have hitherto controlled the normal *nisus formativus* always present. A certain amount of neoformative power must always exist in order to keep any organ up to the standard necessary for function, and it is the failure of the connective tissue properly to limit this force that constitutes, under some circumstances, at least, the essence of malignancy. Once cells have acquired the habit of overgrowth, like microbes, they are prone to take on special virulence, and hence the occurrence of metastases and the development of cachexia because of the oversecretion of toxic cellular products.

1. Pathologische Anatomie und Krebsforschung. Bergmann, Wiesbaden, 1902.

Medical News.

CALIFORNIA.

Personal.—Dr. Leonard Stocking has been elected medical superintendent of the Agnew State Hospital; Dr. George D. Marvin has been promoted to be first assistant physician, and Dr. Edwin A. Kelley, Berkeley, has been appointed to take charge of the male department of the institution.——Dr. Titian J. Coffey, Los Angeles, is taking a course of special study in the East, and will visit Europe.

New Hospitals.—Sonoma County is to have a new county hospital at Santa Rosa, to cost $40,000.——The new Emergency Hospital on Crocker street, Los Angeles, was formally opened January 26.——A free polyclinic was opened at San Francisco, January 22, under the patronage of the Emanuel Sisterhood.——Plans are being matured for a $100,000 Methodist Hospital at Los Angeles.——Sequoia Hospital has been incorporated by five physicians of Eureka, with a capitalization of $50,000.

Proposed Medical Laws.—A bill has been introduced in the Senate for the regulation of the practice of medicine and surgery in the State of California and for the appointment of a board of medical examiners in the matter of said regulation. It is provided that the board shall consist of nine members, to be appointed by the governor, as follows: Three members from the State Medical Society, three members from the State Homeopathic Medical Society, and three members from the State Eclectic Medical Society. A bill of similar import was introduced in the House by Representative G. S. Walker, and Representative McMartin of San Francisco is fathering a measure which provides that each school of medicine may issue licenses to practice to its own graduates. Against the passage of the latter bill the Santa Clara County Medical Society has entered an energetic protest, for the following reasons:

That in matters of education it is retrogressive, inasmuch as the present medical law requires a fair knowledge of the fundamental principles of medicine, surgery and obstetrics, while the proposed law seeks to eliminate this requirement by abolishing examinations

which now exclude from practice the unlearned and incompetent graduates of mercenary and notoriously disreputable medical colleges.

That under the existing statutes of California any body of men can incorporate a medical college and lawfully confer degrees and issue diplomas. Should assembly bill No. 129 become a law it will encourage the establishment of new diploma mills under the guise of medical colleges, whose output would receive certificates from a state board to practice medicine on presentation of such diplomas, and overrun the state, becoming a curse to the communities in which they may locate and a source of degradation to the medical profession.

That the bill encourages the incorporation of unscrupulous persons into various "legally chartered medical societies," which by their numerical strength as opposed to bona fide state medical societies can compel the governor to appoint members of the State Board of Medical Examiners of their own selection and for their own private interests, thus taking the election of members of the state board out of the province of the three state medical societies.

That the bill discriminates against graduates of colleges and universities of other states by compelling them to submit to an examination by the State Board of Medical Examiners and payment of a fee of $25, while graduates of medical colleges of California are made exempt from such examination of qualification and are admitted to practice on the payment of a fee of only $10.

DISTRICT OF COLUMBIA.

Personal.—Surgeon-General Presley M. Rixey gave an address in Jefferson Medical College, Philadelphia, February 3, under the auspices of the H. A. Hare Medical Society, on the opportunities of medical men in the Navy. A reception and banquet in his honor followed.

Health of the District.—During the week ended February 7 122 deaths occurred, 73 were white and 49 colored individuals. One hundred and seven births were reported, of which 69 were white and 38 colored. During the week there were under treatment 130 cases of typhoid fever, 11 of scarlet fever and 5 of diphtheria and 8 of smallpox.

Typhoid Fever Statistics.—The records of the health office from July 1 to Dec. 31, 1902, show that 1,290 cases of typhoid fever were reported, with 156 deaths. In 25 cases no personal history was obtainable; 154 cases are believed to have been contracted outside of the district; 93 by direct exposure to other cases, and 21 through infected milk; while in 997 cases the only cause associated was the drinking water. The Potomac water was supposed to have been used in 729 patients, and in 103 cases Potomac and other waters were used. Well water was said to have been used exclusively by 99 patients, spring by 28, spring and well water by 31 and melted ice by 7.

ILLINOIS.

Scarlatina at Lake Forest.—Lake Forest is to be a closed town as regards church and other public gathering places, for three weeks, on account of the prevalence of scarlet fever.

The Governor's Message.—In his message to the legislature, Governor Yates recommends the formation of a State Board of Medical Examiners, and an increase in the appropriation for the State Board of Health.

The Sale of Cocain.—The January grand jury of Cook County in its report noted the alarming growth in the sale of cocain and recommended that every step possible under the law be taken to confine its sale within legitimate bounds.

No More Fees at County Hospital.—The warden of Cook County Hospital has decided that the only fee heretofore permitted to be collected at the hospital, namely, that for filling out proofs of death for life insurance companies, shall be abolished.

Honor Dr. Catlin.—The Winnebago County Medical Society honored one of its oldest members, Dr. Edward P. Catlin, Rockford, at a banquet given in his honor, February 10. Dr. William H. Fitch presided and extended the greetings of the society to its honored guest.

State Care of Consumptives.—In his message the governor recommended the construction of a state sanatorium for consumptives for the following reasons cited in its report by the State Board of Health:

1. Tuberculosis, an infectious disease, is the cause of one-seventh of all deaths, and that its widespread prevalence, especially among the poor who are unable to procure proper treatment, has been, and continues to be, a decided menace to the public health. 2. It is estimated that over 8,500 persons die annually in Illinois from tuberculosis. 3. Tuberculosis is a preventable disease; and while there is no infectious disease which causes such disaster in the human family, there is none which is more easily prevented. 4. Tuberculosis is a curable disease, especially in its earlier stages. 5. Patients suffering from tuberculosis, especially those of the poorer classes, can not be properly cared for at their homes; general hospitals are ill adapted for the treatment of consumptives, and, since tuberculosis has been recognized as a communicable disease, the doors of nearly all hospitals, public and private, have been closed to consumptives. 6. An improperly cared for consumptive daily jeopardizes the health of the community in which he lives. 7. The state, for both humanitarian and economical reasons, should care for the consumptive, and should prevent him from endangering the lives of those about him. 8. The successful treatment of tuberculosis requires the segregation, in properly constructed hospitals, of those patients who can not receive the needful care at home; the value of sanatorium treatment as a center of education, a means of prevention, and as a method of cure, has been successfully demonstrated at home and abroad. 9. The importance of a special climate, altitude or atmosphere in the treatment of consumptives has been exaggerated; the treatment and cure of pulmonary tuberculosis is as feasible in the State of Illinois as in any state of the Union, and cures effected in the ordinary home climate, in which the patient must remain, are more lasting and more assured than cures obtained in other climates apparently more favorable.

Chicago.

Deaths of the Week.—The total 638 deaths from all causes reported during the week increases the mortality rate 6.5 per cent. over that of the previous week and 12.3 per cent. over that of the corresponding week of 1902. The rate for the week was at the annual rate per 1,000 of 17.56, an unusually high rate for Chicago. Pneumonia, Bright's disease, heart diseases and the chronic maladies generally contribute to the excess of deaths, and the privations and sufferings caused by the coal shortage are especially reflected in the excessive death rates among the young and the aged.

Children's Hospital Society.—Despite the storm the meeting of this society on Sunday was well attended. Drs. Billings, Abt, Henrotin, Engelmann, Christopher and others explained the objects of the organization. Dr. Fernand Henrotin was appointed chairman of the advisory committee, and Dr. Isaac A. Abt chairman of the medical and visiting committee. Instead of building a separate hospital it was decided to create an endowment fund to enlarge and improve the hospital facilities already existing for the care of sick children and to coordinate the various philanthropic interests involved.

MARYLAND.

Baltimore.

Vital Statistics.—Measles is on the decrease, only 141 new cases being reported last week. 215 deaths were reported, a rate per 1,000 of 20.60. Pneumonia led in the causes of death with 43. There were 20 deaths from consumption, 7 from grip, and 3 from measles.

Personal.—Dr. Alexand. H. Saxton has been elected physician to St. Mary's Industrial School, to succeed the late Dr. R. H. Goldsmith.——Dr. Simon Flexner will resign his chair in the University of Pennsylvania to assume charge of the new Rockefeller Research Laboratory about to be erected in New York.

The Ginger Blindness Case.—The "Jamaica Ginger Case," which was tried in the Superior Court, resulted in a disagreement of the jury after a trial of 14 days. The jury stood 9 for Dr. Brehm, the blind plaintiff, and 3 for the drug firm. Four other cases are pending, 3 for blindness and 1 for death, alleged to have resulted from drinking essence of Jamaica ginger containing wood alcohol.

New Physiologic Laboratory.—Owing to the unusual size of the first-year class at the Johns Hopkins Medical School, which numbers this year 100 students, a new laboratory on the first floor of the physiologic building has been completed for the course in physiological chemistry, under Dr. Walter C. Jones, associate professor of physiological chemistry and toxicology. It accommodates 32 students and is provided with the most approved apparatus and conveniences.

The Alumni Awake.—There is a great awakening at the University of Maryland and, with the formation of a general alumni association, a strenuous effort will be made at reorganization and endowment. A fund is being collected among the alumni of the medical school, to be known as the "Centennial Endowment Fund," and, as the medical school will celebrate its centennial in 1907, an appeal is being made to all the medical alumni throughout the country in behalf of this special fund. The secretary-treasurer is General Lawrason Riggs, Baltimore.

Carnegie Institute Grants.—The authorities of the Carnegie Institute have just awarded 5 grants to Johns Hopkins

University for research work. One is to Dr. John J. Abel, professor of physiological chemistry, of $1,000 for the purchase of apparatus necessary in his work. A great deal of the apparatus used by Dr. Abel has to be made specially for his purpose, and the cost is often very high. The other grants were to the departments of electricity, physics, analytical chemistry, and physical chemistry. These appropriations are among the first that have been made.

MINNESOTA.

Consolidation Proposed.—On account of the light registration in the homeopathic department of the state university it has been suggested that the department be consolidated with the regular school, with a chair of homeopathic medicine.

Smallpox.—There were 324 new cases of smallpox reported to the State Board of Health during the week ending February 2. The majority of these cases are old ones, however, that were not reported when they occurred, and were discovered on a recent visit of inspection to Douglas and Otter Tail counties. Douglas County reports 149 cases, 100 of which are in Millerville, and 20 in Leaf Valley. Rice County reports 80 cases, 64 of them in Webster and 16 in Wheatland. Otter Tail County reports 33, Hennepin 7, and Ramsey 3.

Personal.—Dr. Alexander J. Stone, St. Paul, has succeeded Dr. Albert A. Ames, formerly of Minneapolis, as surgeon-general of Minnesota, with rank of brigadier-general.——Dr. Rudolph Schiffman, St. Paul, president of the assembly, has been granted a five months' leave of absence and has started for the Orient.——Drs. Malcolm McKinnon, Forston, and Charles W. More, Eveleth, have been appointed members of the State Board of Health.——Drs. Eric O. Giere, Madison, and Carl J. Rignell, Minneapolis, have been appointed members of the State Board of Medical Examiners.

MISSOURI.

Hospital Opened.—The A. R. Levering Hospital, Hannibal, was formally opened with imposing ceremonies, February 5.

To Honor Old Practitioners.—The St. Louis Medical Society is about to give a banquet in honor of Drs. Simon Pollock, who has practiced 68 years; William Johnston, who has practiced 65 years, and William M. McPheeters, who has practiced 63 years.

Bill for Three Boards.—Dr. Quig of Cooper County has introduced a bill in the house providing for the appointment by the governor of three separate medical boards, one for each of the three "schools." Each board is to consist of five members and is to examine applicants for the respective schools and issue licenses to those found qualified.

World's Fair Medical Report.—Medical Director Leonidas H. Laidley of the World's Fair has made a report on the state of health of the persons residing on the World's Fair grounds and employed there. One death occurred from a fall at the electricity building. During December 93 cases were treated at the Emergency Hospital on the grounds. Of these 53 were surgical and 43 medical. One birth is reported. The number of residents on the grounds is estimated at 395.

Personal.—Dr. Albert L. Brown, police surgeon of Kansas City, has resigned and has been succeeded by Dr. A. E. Eubanks.——Dr. Abra C. Pettijohn, Brookfield, has been confirmed as member of the State Board of Charities and Corrections.——The appointments of Drs. John T. Thatcher, Oregon; Winn F. Morrow, Kansas City; Benjamin G. Dysart, Paris; A. W. McAlester, Columbia; Dempsey T. Powell, Thayer; J. Alfred Adcock, Warrensburg; and Mont M. Hamlin, St. Louis, as members of the State Board of Health, have been confirmed by the Senate.

NEW YORK.

Protest Against Hospital Admitting Fever Patients.—Twenty-five physicians of Niagara Falls have signed a petition to the trustees of the Louise Memorial Hospital protesting against its use for scarlet fever quarantine purposes, stating that its usefulness as a maternity hospital and for surgical operations would be for a long time destroyed by allowing fever patients there.

Warning Renewed.—In the issue of February 7, the readers of THE JOURNAL were warned against one F. Whiting who had been endeavoring to collect money on account of THE JOURNAL and of the American Medical Association. We are now informed that this fraud has been operating in Binghamton, and warn all physicians against paying any money to him, as he is unauthorized. THE JOURNAL will appreciate any information regarding this person's whereabouts.

Pure Water for Niagara Falls.—Niagara Falls, which is now drinking Niagara river water polluted by the sewage of Buffalo, and where there are usually 400 to 500 cases of typhoid fever in a year, will hereafter be supplied by the Western New York Water Company, which has absorbed the Niagara Falls Waterworks Company. Eventually the Western New York Water Company will abandon its water supply from Niagara river and will pump water from Lake Erie, three miles above Buffalo and over 7,700 feet from shore.

Typhoid at Ithaca and Cornell.—In a letter written by President Schurman of Cornell University, he complains of the sensational newspaper reports regarding the prevalence of typhoid at Cornell University. There are, however, 55 students ill with the disease, most of the cases being mild, while two or three are critical. In a census taken among physicians it was found that an additional number of ten students are ill with the disease outside of the infirmary. There is also one serious case in the city hospital. The cause of the typhoid is the contamination of water supply for the city of Ithaca. Fortunately Falls Creek, which supplies Cornell University, is not contaminated. It is supposed that the present epidemic can be traced to Italian and Hungarian laborers who were working, up to the beginning of winter, on the construction of a new dam which the waterworks company is erecting.

How Not to Deal with Smallpox.—Rochester should serve as an example to all cities whose councils use the *manana* policy of dealing with epidemics, especially that of smallpox. In Buffalo the health commissioner has again and again urged the absolute necessity of the maintenance of a modern quarantine hospital, the plans have at last been prepared and the city will soon have a modern hospital where all contagious cases may be taken and be humanely treated. When Rochester suddenly found herself face to face with an epidemic of smallpox, the city was unprepared to deal with it. The committee of councilmen is now compelled to hear evidence which in no way does credit to the authorities in charge of the Hope Hospital. It was necessary to use election booths and tents, and according to evidence submitted some beds were covered with snow, the bed sheets and bed clothing were filthy, the food was insufficient, the nursing poor and many patients were sent home infested with vermin.

New York City.

Proposed Tuberculosis Camp.—The agitation for better facilities for the great army of consumptive poor in this city has led to the proposition that a lot of suitable tents be erected, thus saving time and money. The plan has the approval of the commissioner of health, and several sites have already been offered.

Wholesale Insurance Frauds.—Insurance circles have been much aroused over the discovery of a plot by which life insurance companies have been systematically swindled for ten years or more. The scheme centers around that portion of the city known as "Little Italy." At present, it is known that about a dozen life insurance companies have been swindled, and that at least 111 fraudulent policies have been issued. Some idea of the extent of the swindle may be inferred from the statement that there is proof that one member of the gang has realized $200,000. The system was worked on a percentage basis, and involved physicians, notaries public, undertakers and others. Drs. Francesco Mucci and Albrecht Loewit, are under heavy bail charged with being parties to the frauds.

Drug and Other Adulterations.—The pharmacists of the city are incensed over the recent publication of the fact that the board of health found that phenacetin was frequently adulterated with acetanilid and other cheaper substances. They call in question the accuracy of the analyses made by the chemist of the health department, and demand a re-examination by a disinterested person. At the last meeting of the Society of Medical Jurisprudence, Dr. H. W. Wiley, chief of the Chemical Division of the Department of Agriculture, talked on some of the dangers that lurk in the things used in daily life. He said that it was not at all uncommon to find a large amount of arsenic in the dyes used for stockings, even in the case of black stockings. The same poison was often found in dress goods and wall paper. The substitution of wood alcohol for genuine ethyl alcohol in bay rum, essence of Jamaica ginger, and other substances, often gave rise to serious consequences. The speaker directed special attention to the great evil arising from the sale of patent medicines under misleading names or with incorrect formulæ. In this way it was no unusual thing for consumers to become addicted to the use of alcohol or of cocain without knowing the nature of the so-called tonics they had been taking.

It was recommended that a system of national and state inspection be established.

Buffalo.

Medical Examiner vs. Coroner System.—Medical Examiner Danser's first annual report to the Erie County Board of Supervisors will show a saving to the county of $7,000 in investigating sudden deaths, as compared to the old coroner's system.

Closed in Memory of Mynter.—The Medical Department of the University of Buffalo was closed February 11, as a mark of respect to the memory of Dr. Herman Mynter, deceased, who occupied the chair of clinical surgery in that institution at the time of his death.

To Lift Hospital Debt.—Mr. Frank Goodyear has contributed $50,000 and Mr. William H. Hamlin $49,900 as a fund to lift the debt of the Buffalo General Hospital. It is expected that $100,000 more will be raised by subscriptions to clear the indebtedness and to make some urgently needed additions to the buildings.

Violators of Anti-Spitting Ordinance Punished.—Because spitting offenders have been usually released by the police justices, their cases will hereafter be considered by the judges of the municipal court. Two convictions for spitting in street cars were obtained in municipal court. One offender was fined $5, the other $2 and costs. The anti-spitting ordinance is to be enforced more rigorously, and 14 patrolmen have been detailed on this duty.

PENNSYLVANIA.

Free Bed Endowed.—By the will of Miss Carrie S. Kinsey of Bristol $5,000 is left to the Methodist Hospital, Philadelphia, to endow a free bed in memory of her father, the late William Kinsey.

To Prevent Tuberculosis.—The Pennsylvania Society for the Prevention of Tuberculosis is urging the passage of a bill by the legislature appropriating $500,000 for the prevention of tuberculosis and the care of incipient cases in the state.

Bill Against Irregular Practice.—A bill introduced into the legislature would so amend the law of 1893 as to punish a person for "entering on or continuing in the profession or occupation of treating disease or injury by the use of medicine or any other means or agency" either for or without valuable consideration, unless the person be licensed under the specified act. The penalty is any sum between $200 and $500, and imprisonment for 30 days to six months. It is said that the bill is designed to check osteopathy and Eddyism.

Fix Blame for Smallpox.—At the "Health Convention" held at Johnstown, February 12, many members of boards of health and county officials were present from various parts of the state. Dr. Benjamin Lee, secretary of the State Board of Health, in replying to the question: "Whose fault is it that smallpox has flourished in Pennsylvania?" placed the responsibility on the discontinuation of infant vaccination; on a class of ill-informed obstructionists calling themselves antivaccinationists; on school directors who have failed to enforce the compulsory vaccination law; on communities which have failed to organize boards of health; and on medical colleges who have been derelict in instructing their students how to recognize the disease. Enforced vaccination was advised by the convention. The governor is urged to use his influence toward securing an appropriation of $50,000 by the legislature to aid in suppressing epidemics.

Philadelphia.

First Aid Lectures to Railroad Men.—Through the president of its board of trustees, Hon. William Potter, Jefferson Medical College has offered a course of free lectures on "First Aid to the Injured," to employes of steam railroads running into Philadelphia. The officials of the roads, in responding, thanked the college officials and favored the plan. It is probable that the proposed course will be arranged.

Many Bequests to Charities.—The estate of Robert J. Wright, recently adjudicated, bequeathes $583 to each of 33 charities. Some of the beneficiaries are as follows: Children's Hospital, Philadelphia; Pennsylvania Training School for Feeble-Minded Children; Philadelphia Home for Infants; St. Christopher's Hospital for Children; Philadelphia Home for Incurables, and Presbyterian Hospital, Children's Ward.

Phipps Institute at Work.—The temporary Henry Phipps Institute for the Cure and Prevention of Tuberculosis has begun active work. Numerous patients are being treated daily at the sanitarium; visits are made to the homes of patients by the staff, and milk and eggs are being provided for the very poor patients. The staff includes, besides Dr. Lawrence F. Flick, the director, Drs. Joseph P. Walsh, Willoughby Irwin and Charles J. Hatfield.

To Aid Library.—Earnest efforts are being made among physicians and others to raise $50,000 to be added to the recent gift of a like sum by Andrew Carnegie for the betterment of the library of the College of Physicians. The library building, which is now greatly crowded, will be enlarged or rebuilt on a new site. The collection of books is the third, possibly the second largest of its kind in the world, and the anatomic and pathologic collection the greatest in the country.

Typhoid, Smallpox and Pertussis.—For the week ended February 14, 287 new cases of typhoid fever were reported, with 23 deaths. Since the beginning of the year 1919 cases have occurred, with 152 deaths. The disease is not of a virulent type. During the week mentioned, 30 new cases of smallpox occurred, with 5 deaths. There were many cases of whooping cough with 15 deaths. The bureau of health has decided that in future all cases of smallpox must be sent to the Municipal Hospital.

Explosion Wrecks Hospital.—On the night of February 12, a boiler in the basement of the Medico-Chirurgical Hospital exploded, doing so much damage to the building that it may have to be torn down. Fortunately there was no loss of life or serious personal injury. A panic was prevented by the cool, prompt action of the hospital officials. As the building did not take fire, no insurance can be recovered. The hospital will consequently be crippled financially. The board of trustees have made a public appeal for aid in a series of resolutions, closing as follows:

Resolved, That we earnestly appeal to our fellow citizens to aid us in our present predicament. We have no funds to meet the expense of repairs, and yet they must be done at once. We can not close our hospital. Every room and bed is full, and the work must go on.

GENERAL.

The Hawaiian Board of Health, January 21, elected Dr. C. B. Cooper president, vice Dr. H. C. Sloggett, resigned.

A famine in Dalmatia and an epidemic of typhoid fever are causing great loss of life. There is very little medical assistance to be had.

More Hospital Cars.—The Erie Railroad has a hospital car and will place similar ones on each division, ready for speedy dispatch to accidents.

American Money for India.—It is reported that Henry Phipps, director of the Carnegie Steel Company, has given $100,000 to establish an agricultural laboratory and a Pasteur institute in India.

German Faker Convicted.—Herr Nardenkoetter, who has been a notorious advertising faker in Berlin for years, was fined $900 and to be imprisoned three years. He forfeited bail and escaped to England. He had contrived to defy the medical societies and public prosecutors until recently.

Carbolic Injections in Tetanus.—Several cases of tetanus are reported in the newspapers with the treatment by carbolic acid injections. The papers treat it as a new discovery. It has been used for several years. The strengths reported are 4 and 10 per cent. In one case 10 drops were injected every three hours. It will be remembered that this remedy is also of value in diphtheria.

A Model Surgical Clinic at Marseilles.—Pantaloni's new model clinic at Marseilles, erected by private enterprise, is described by Baudouin in the *Gaz. Med. de Paris* with many illustrations. Hot, sterilized water is freely supplied on all the five floors. The elevator is large enough for a bed to be wheeled into it. The bath tubs are in the center of the bath rooms, instead of at the side. Among the innovations is a room specially designed for physicians from outside to meet and prepare to witness or aid in operations.

Collection of Appliances for Medical Instruction.—The exposition on these lines held in Berlin last year proved so popular that the authorities are organizing a permanent collection as a museum, and also for loaning on demand. It is expected that the articles will be found useful in the preventive lectures, both in regard to venereal diseases and tuberculosis, and also in popular courses on hygiene, etc. There are to be twelve different exhibits: 1 and 2, specimens of anatomy and pathologic anatomy; 3, microscopic specimens; 4, casts depicting various diseases; 5, photographs and atlases; 6 to 8, lantern, stereoscope and kinematograph slides; 9, appliances for technic of microscopy; 10 to 12, apparatus for demonstrations.

Less Plague in Mexico.—The bubonic plague is subsiding in Mexico. There has been a hysterical tendency—as is com-

mon in such cases—of spreading unfounded reports of the disease existing at other points. One of these rumors was concerning Hermosillo, and the authorities of that libeled place traced it down, says the *Los Angeles Times*, to one of their citizens who had reported to friends that a certain young man had the plague. He was arrested and told the judge that it was a joke. The judge thought the joke was not carried far enough, and sent the joker to the chain gang for sixty days. All authorities of towns and of railroads have been notified by the government to hold all persons who spread rumors.

The dengue epidemic in Honolulu is causing much suffering and is particularly prevalent among school children. At last reports schools had not closed, although classes were interfered with by the large numbers of those absent. The last epidemic of dengue in the islands was in the seventies. The great attack was in 1852, when a ship from Panama loaded with gold seekers bound for San Francisco stopped at the port of Lahaina in distress. There was much sickness on board, as well as scarcity of food and water, and dengue was brought ashore and caused much sickness. The present visitation began about the middle of January. The infection is thought to have been brought on transports from Manila or else by Porto Ricans, on whose island the disease is endemic.

New Biochemical Journal.—A new publication has appeared in Berlin issued by Carl Oppenheimer, under the direction of Ehrlich, Fischer, Kossel, Liebreich, Muller, Proskauer, Salkowski and Zuntz, with Heinrich Stern, New York, editor for the United States and Canada. The object of the publication will be:

A. To report such experiments and observations of physical and employed chemistry as are of importance to the physician.

B. Reports on the physiology of plants.

C. Physiologic chemistry in the narrower sense (constituents of the body and their derivates).

D. Chemistry of the tissues and organs under normal and pathologic conditions.

E. Chemistry of digestion, secretions and excretions, metabolism and blood.

F. Ferments and fermentations, toxins of a non-bacterial nature.

G. Chemistry of the pathogenic micro-organisms (toxins, antitoxins), phenomena of immunity.

H. Toxicology and pharmacology.

I. Hygienic chemistry, disinfection, examination of water.

This interesting field, in which so much advance is being made, needs an organ of its own. The American editor writes us that he is anxious to receive abstracts of papers on work done by American physicians in these branches.

That Decreasing Birth Rate.—Great interest is taken in the alleged decrease in the birth rate. The newspapers of the country are giving much space to articles, interviews, editorials and columns of statistics. The clerks in the Census Bureau are reported to be busy compiling statistics for inquirers. Some of these statistics are quoted as follows: The average size of families in the United States has steadily decreased in the past 50 years, as follows: 1850, 5.6; 1860, 5.3; 1870, 5.1; 1880, 5; 1890, 4.9; 1900, 4.7. It has increased since 1890 only in North Dakota, South Dakota and Oklahoma from 4.7 to 4.9, from 4.7 to 4.9, and from 4.1 to 4.6 respectively. In Connecticut and Rhode Island it remained stationary, and in all other states it decreased. From 1880 to 1890 there was an increase in all the states in the western division and in the south Atlantic states. The birth rate for the entire United States in 1890 per thousand of population was 26.9. The birth rate per thousand of population in 1900 was 27.2. In the northeastern division of states the birth rate per thousand of population was as follows, the first figure being that for 1890 and the second for 1900:

Connecticut, 22.3 and 24; Maine, 17.6 and 21.1; Massachusetts, 21.5 and 24; New Hampshire, 18 and 21.3; New York, 23.3 and 24.2; Rhode Island, 22.3 and 24.3; Vermont, 18.3 and 21.3.

In the central and northern divisions the average birth rate for 1900 was 25.9 and for 1890 it was 26.8.

In the southern division the average birth rate was, in 1900, 31.5, and in 1890 it was 30.1.

In the western division the average birth rate, per 1,000, was 22.8 in 1900 and in 1890 it was 22.9.

By the birth places of mothers of United States children these are the percentages showing the birth per 1,000 of population as based on the census of 1900:

Ireland, 32.7 per 1,000; Germany, 32.6; England and Wales, 25.4; Canada, 37.0; Scandinavia, 46.7; Scotland, 30.1; Italy, 60.9; France, 18.4; Hungary, 65.5; Bohemia, 57; Russia, 64.6, and all other countries, 56.9.

These figures are not verified by us. The Census Bureau admits that its birth statistics are very unsatisfactory. Most of the comparisons are made between the birth rate and death rate, and the percentages are given in those conditions.

Amending the Statutes Relating to Patents.—Senator Platt of New York has introduced a bill in the Senate, No. 7062, entitled, "Amending the Statutes Relating to Patents," relieving medical and dental practitioners from unjust burdens imposed by patentees holding patents covering methods and devices for treating human diseases, ailments and disabilities, which provides that Section 4886 of the Revised Statutes be amended. The original reads as follows:

Any person who has invented or discovered any new and useful art, machine, manufacture or composition of matter, or any new and useful improvement thereof, not known or used by others in this country before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof, or more than two years prior to his application, and not in public use or on sale in this country for more than two years prior to his application, unless the same is proved to have been abandoned, may, on payment of the fees required by law and other due proceedings had, obtain a patent therefor.

The following it is proposed to add:

But no patent shall be granted on any art of treating human disease, or ailment, or disability, or on any device adapted to be used in the treatment of human disease or disability, or attached to the human body and used as a substitute for any lost part thereof, or on any art of making such device, unless such device is adapted to be put on the market and sold.

The bill further would amend Section 4921, which reads as follows:

That the several courts vested with jurisdiction of cases arising under the patent laws shall have power to grant injunctions according to the course and principles of courts of equity to prevent the violation of any right secured by patent, on such terms as the court may deem reasonable; and on a decree being rendered in any such case for an infringement the complainant shall be entitled to recover, in addition to the profits to be accounted for by the defendant, the damages the complainant has sustained thereby, and the court shall assess the same or cause the same to be assessed under its direction. And the court shall have the same power to increase such damages, in its discretion, as is given to increase the damages found by verdicts in action in the nature of actions of trespass on the case.

But in any suit or action brought for the infringement of any patent there shall be no recovery of profits or damages for any infringement committed more than six years before the filing of the bill of complaints, or the issuing of the writ in such suit or action, and this provision shall apply to existing causes of action.

The amendment would add the following:

Nor shall any suit or action be maintained for the infringement of any patent for an art of treating human diseases, or ailment, or disability, or for any patent for any device adapted to be used in the treatment of human disability, ailment or disease, or attached to the human body and used as a substitute for a lost part thereof, or an art of making such device, unless it appear that such device can be made and put on the market.

The bill is to "take effect immediately on its passage, but the paragraph added to Section 4886 shall not be held to apply to any application for patent filed prior to the passage hereof nor to patents granted on applications filed prior to said date; nor shall the amendment to Section 4921 affect the rights of action that may have occurred prior to the passage hereof."

CANADA.

Smallpox at Galt, Ontario, Under Control.—The epidemic of smallpox which has lately been causing some alarm in Galt, Ontario, is now said to be practically at an end. In all there have been 81 cases, affecting 21 families, with 5 deaths. The number now in the isolation hospital is 16. Dr. Macdougall King of Toronto has had charge of the isolation hospital.

Prevention of Tuberculosis in Montreal.—Definite steps have now been taken by the Montreal League for the Prevention of Tuberculosis. The executive committee met last week and received the report of the special committee on organization. Dr. A. J. Richer was appointed permanent secretary. Dr. Labergeg, M.H.O., has promised to recommend to the city council that the city give assistance. The Victorian Order of Nurses will co-operate. The Provincial Board of Health, through Dr. Lachapelle has offered to look after the distribution of literature among the poorer classes.

Toronto's New Medical Building.—A deputation from the medical faculty of Toronto University waited on Premier Ross one afternoon of last week and asked for an additional loan of $50,000 to complete the new medical building. The previous arrangement with the government was for a loan of $125,000, but it has been found that that amount will be inadequate. The new building is nearly completed, and when finished, it is said, it will be the finest type of modern college building on this continent. Toronto has now the largest roll of any medical college in Canada, even leading McGill; the number this season is 420. The main building is entirely planned on the unit system, the standard size of the classrooms being twenty-three by thirty feet.

Ontario Health Report.—The regular quarterly meeting of the Ontario Board of Health was held last week. Smallpox, vaccination, scarlet fever and the septic tank method of sewage disposal were the chief subjects under discussion. Secretary Bryce stated that during 1902 there had been in Ontario 2,500 cases of smallpox, resulting in 10 deaths. Of scarlet fever there had been 3,119 cases, with 266 deaths. In January, 1903, smallpox had existed in 42 centers and there had been 196 cases and 10 deaths, compared with 650 cases and 1 death in January, 1902. The most serious outbreak had occurred at Galt. Of the 5 cases which died at Galt, not one of them had ever been vaccinated. Out of a total population of 8,000, 5,000 were vaccinated in January. Toronto, Windsor and Walkerville were the only municipalities in Ontario in which general vaccination was practiced, although there had been a law on the statute books for forty years calling for compulsory vaccination of infants born every year. Later on the board approved a draft bill to be submitted to the coming session of the legislature making more effective the vaccination law. Scarlet fever had been more virulent than for years. In Toronto alone during the last six months of 1902, there had been 701 cases, with 88 deaths. The death rate had been 9 per cent. in the cities generally, and 12.5 per cent. in Toronto, while in January, 1903, there had been 106 cases and 21 deaths, a much higher percentage. The board also discussed the experimental sewage purification work done by the laboratory of the board last year at the town of Berlin, and reported favorably on the septic tank system.

FOREIGN.

The cancer research fund in England has been swelled by $50,000 from the Coats family.

Campaign Against Charlatans in Germany.—The last issue of the *Allg. Med. Ct.-Ztg.* mentions four suits against charlatans, resulting in the imposition of a fine of $250 each on two, and the condemnation to six months' and eighteen months' imprisonment of two prayer healers.

The Second International Congress of the Medical Press will meet at Madrid, April 20 to 22, immediately before the opening of the International Medical Congress. The members are entitled to the same rebates and privileges as the members of the latter. The general secretary is Dr. Larra Corezo, 17 Leganitor, Madrid.

St. Bartholomew's Hospital, London, is asking for $1,500,000 to build additional buildings on the adjoining land it has purchased. It is located in a shop and warehouse district, and could sell its valuable site for enough to buy and build where land is cheaper. This hospital has never publicly asked financial aid before, and has been proud of the fact.

Prophylaxis of Venereal Diseases.—Munich and Bavaria are organizing a society for the prevention of the spread of venereal diseases. The meetings are held, like those at Berlin, in the city hall, at 11 a. m., on Sundays. The *Muenchener Med. Woch.* issues an appeal to physicians to help make the society a success, "to show that the profession, as always, takes the lead in matters involving the suppression of disease."

Preventive Congress in Germany.—The German Society for the Combating of Venereal Diseases will hold its first congress March 9 and 10 at Frankfort. a. M. Some of the addresses will be on the themes: "Legal Responsibility for Menace to Health by Persons with Venereal Disease"; "Venereal Diseases in Their Legal Relations"; "How Can the Physician by His Advice Prevent the Spread of Venereal Diseases?" etc.

The Unna Prize.—The prize of $75 offered by Unna for the best work on the coccus found in eczema with discharge, was not awarded in 1902. The sum is therefore doubled, and further competition invited. The coccus is the *Diclimacterious albus flavens* (*Typus Traubel*), and it must be studied in comparison with the pyogenic staphylococci. Articles must be sealed and received by Leopold Voss, Hohe Bleichen 34, Hamburg, before December, 1903.

Serum Cure for Scarlet Fever.—Prof. Dr. Adolf Baginsky, Berlin, is reported by cable as having announced remarkable results from the use of antistreptococcus serum. Baginsky modestly disclaims any credit for the discovery of the serum, the honor of which he accords to Herr Aronson. The only credit he takes to himself is the discovery that scarlet fever, like erysipelas, is caused by the streptococcus. During the past 12 years 701 patients have been placed under the serum treatment, and the mortality from the disease has been reduced to 8 per cent.

Trachoma in Germany.—The medical inspectors of the schools of Prussia did not find a single school in which less than 5 per cent. of the children were affected with granular lids. In the villages the proportion averaged 20 to 48 per cent. and at one place more than half the children were affected. Rachlmann states that more than half a million persons suffer from trachoma in three provinces alone. The government appropriates every year $87,500 to fight it, but still more energetic measures are demanded by the Berlin medical press.

LONDON LETTER.

Recent Researches in Malaria in India.

An important contribution to our knowledge of malaria has been published in Calcutta by S. P. James, army surgeon, who is on special duty with the Royal Society's commissions on malaria. It forms one of the new series of "Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India." In some of the work he was associated with Dr. J. W. W. Stephens and Dr. S. R. Christophers. In his classification of Indian anopheles Dr. James recognized 16 species, among which *Anopheles fluviatilis* and *Anopheles culicifacies* are the most common conveyers of malaria. *Anopheles rossii* is almost certainly the commonest species in India and three species of the human malaria parasite can be made experimentally to develop in it, but Dr. James never yet found it infected in nature. Of the remaining species most are either rare or are seldom found in human habitations or have not been found infected with malaria in the natural state. It has been suggested that the naturally uninfected anopheles may bite only cattle and horses. It has been discovered that the embryos of *Filaria sanguinis hominis* can develop in *Anopheles nigerrimus* and *Anopheles rossii*. In consequence of the difficulty which is usually found in the identification of the different species of Indian anopheles, Dr. James recommends a classification in three primary subdivisions determined by the palp markings—namely, (1) palpi unbanded; (2) palpi with four white bands; and (3) palpi with three white bands. Dr. Christophers has made the important observation that anopheles not only select their breeding places but that each species has a particular kind of breeding ground that it prefers to any other. There is evidence that the mosquitoes which infest human habitations will readily fly to a breeding place a quarter of a mile away, but that they will hardly ever fly over three-quarters of a mile. Koch and, independently, Dr. Stephens and Dr. Christophers discovered that a large percentage of native children in Africa constantly have malaria parasites in their blood, although they may present none of the more evident clinical symptoms of malaria fever. Dr. James has confirmed and extended these observations for certain parts of India, in some of which there is an infection of from 60 to 75 per cent. of the children under 10 years of age, with no infection of adults. This percentage of infected children, he says, affords a true test of the endemicity of malaria and the figure representing it may be termed the "malarial endemicity index," or, shortly, the endemic index. These children are the chief source from which anopheles mosquitoes become infected. As in Africa so in certain highly-malarious districts of India, there is a diminished infection of the children with advancing age, and the adults are relatively immune, but in less malarious districts in India the immunity of the adult native is not so marked and the diminished infection of the children at advancing age-periods is not shown. It has been said that these infected children present no clinical symptoms of malaria, but Dr. James finds that in the evening many of them have to lie down, their temperatures rise, and careful examination shows that their general health is seriously affected. One in whom quartan parasites were found was only nine months old.

The Plague.

India: During the weeks ending December 27, January 3 and 10 the deaths from plague amounted to 15,827, 15,686, and 16,197 respectively. During the first week of January, 1902, the mortality was only 10,386. Thus there is an enormous increase this year when the disease is more widespread than at the commencement of any previous year. In the Punjab there has been a marked decrease from 2,238 deaths for the week ending January 10 to 1,236 for the week ending January 3. In the Bombay Presidency the deaths for the three weeks mentioned were 7,025, 7,295 and 8,440 respectively. In the city of Poona the increase is serious. On January 15 118 fresh cases and 98 deaths were reported. Hundreds of people have left the city for segregation camps. *South Africa:* Plague continues to prevail in Durban. On January 26 42 cases were re-

ported, of which 27 were fatal. On that date 3 Europeans, 7 natives and 3 Indians were under treatment.

Vital Statistics for 1902. Lowest Death Rate on Record.

According to the returns furnished by the local registrars to the Registrar-General 942,819 births and 537,080 deaths were registered in England and Wales during the year 1902. The natural increase of population by excess of births over deaths was, therefore, 405,793, the average annual increase in the preceding 5 years having been 363,053. The birth rate was 28.6 per 1,000 of the population, which is 0.1 per 1,000 higher than the rate in 1901, but lower than that in any other year on record, and compared with the average in the preceding ten years shows a decrease of 1.0 per 1,000. The death rate was 16.3 per 1,000, which is the lowest rate on record, the only previously-recorded rates below 17 per 1,000 having been 16.5 in 1894 and 16.9 in 1901, and as against the last decennial average it shows a decrease of 1.6 per 1,000.

The "Sleeping Sickness." Departure of Commissioners for Uganda.

Lieut.-Col. Bruce and Dr. Nabarro, the new commissioners who are being dispatched by the government and the Royal Society to study sleeping sickness in Uganda, will leave England on the 12th inst. The duration of their stay in Uganda will probably be not less than from 6 to 12 months. Colonel Bruce is the discoverer of the parasite in the tsetse-fly disease and also of Malta fever. He was in Ladysmith during the siege.

Marriages.

Henry W. Curtin, M.D., to Miss Lottie Carten, both of St. Louis, February 4.

D. L. Rose, M.D., Sherman, Mich., to Miss Gail Hooper of Battle Creek, Mich., January 31.

George H. Brett, M.D., Williamston, Mich., to Miss Frieda Paulina of Chicago, January 12.

Henry M. Nedry, M.D., Dachester, Wis., to Miss Minnie Rosin of Colby, Wis., at Minneapolis, January 21.

Oscar Chrysler, M.D., National Home, Milwaukee, Wis., to Miss Birdseye Knox, at Meadowmere, Wis., February 18.

Deaths.

Herman Mynter, M.D.

By the death of Dr. Herman Mynter, which occurred at his home in Buffalo, N. Y., February 9, at the age of 58, America has lost a great surgeon and surgery one of its most earnest and honest exponents. He was born in Kereack, Denmark, and was graduated in medicine from the University of Copenhagen, in 1875. After serving four years in the Danish navy he came to Buffalo, which he afterward made his home. He was a surgeon of international repute, an acknowledged authority on appendicitis, and his contributions to surgical literature were always thoughtful, well considered and valuable.

He was a professor of surgery in Niagara University, and after the amalgamation of this school with the Medical Department of the University of Buffalo became professor of clinical surgery in the latter school. He was surgeon to the German Deaconess and the German Hospital, a member of the Buffalo Academy of Medicine, Buffalo Physicians' Club, Erie County Medical Society, Medical Society of the State of New York and the American Medical Association. Dr. Mynter's name came into great popular prominence through his connection with the case of President McKinley. He was the first to answer the summons after the President was shot, and was intimately connected with the case until the fatal termination.

Last summer he paid a visit of several months to his fatherland, where he was accorded the high honors to which his ability entitled him. He was taken ill with myocarditis, and was confined to his bed for ten days before his death, which occurred February 9, at 10:30 p. m. He was attended in his last illness by Drs. Charles Cary, Henry R. Hopkins and Charles G. Stockton. The cause of death is stated to have been myocardial fatty degeneration. The loss of Dr. Mynter will be keenly felt by the laity, and especially by his colleagues, by whom he was greatly respected because of his superior skill as a surgeon and his many scholarly and gentlemanly qualities.

John Homans, M.D. Harvard University Medical School, Boston, 1862, a pioneer in abdominal surgery and the third surgeon of his family by lineal descent; who served both in the Navy and Army in the Civil War, being medical director of the army of the Shenandoah at its close, died at his home in Boston, February 7, after an illness of two weeks, aged 66. He was a member of the Massachusetts Medical Society, the Boston Society Medical Improvement, surgeon to the Boston Dispensary, the Children's Hospital, the Carney Hospital and the Massachusetts General Hospital, and was lecturer on surgery at Harvard Medical School.

John Ridgely, M.D. University of Maryland, Baltimore, 1841, a veteran of the Mexican and Civil wars, a member of the party which explored the Yukon River in the early 40s, for the last 12 years keeper of the National Cemetery at Fort Harrison, near Richmond, Va., died at his home in that place, February 4, aged 83.

Benjamin F. Eads, M.D. University of Pennsylvania, Philadelphia, 1856, a member of the American Medical Association and chief surgeon of the Texas and Pacific Railway, died suddenly at his home in Marshall, Texas, February 1. He had been in feeble health for some time.

Thomas N. De Bowes, M.D. New York University, 1858, surgeon of a Connecticut regiment in the Civil War, and for fifteen years autopsy physician for New York City, died from infirmities incident to old age, after an illness of two months, February 7, aged 70.

Arista O. Lucas, M.D. Western Reserve University, Cleveland, Ohio, 1891, a member of the American Medical Association, died at his home in New Washington, Ohio, February 3, from tubercular peritonitis, after an illness of nearly four months, aged 37.

Thomas Jefferson Grove, M.D. Medical School of the Valley of Virginia, Winchester, 1849, a surgeon in the Confederate service during the Civil War, died at his home in Petersburg, W. Va., February 1, from paralysis, aged 74.

Fairfax Schley, M.D. University of Maryland, Baltimore, 1846, who retired from practice to engage in the drug business nine years later, died at his home in Frederick, Md., February 1, from heart disease after a brief illness, aged 79.

Henry W. Allan, M.D. Bellevue Hospital Medical College, New York, 1882 died from the effects of a self-administered dose of hydrocyanic acid, at a drug store near his residence in East New York, February 5, aged 48.

Archibald E. Covert, M.D. New York University, 1892, a member of the staff of the J. Hood Wright Hospital, New York City, died in that institution, February 2, from Bright's disease, after a short illness, aged 32.

William W. Hinish, M.D. Miami Medical College, Cincinnati, 1875, was found dead in his office in Chicago, February 10, from the effects of morphin, taken, it is alleged, with suicidal intent, aged 60.

Charles L. Floor, M.D. Western Reserve University, Cleveland, 1882, died at his home in Youngstown, Ohio, January 30, nine days after an operation for abscess of the lower bowel, aged 44.

Erasmus M. Chapin, M.D. Columbian University, Washington, D. C., 1841, died at his home in Washington, D. C., February 8, from shock following a fall the day before, aged 82.

Charles Collins Bradley, M.D. Willoughby (Ohio) University Medical Department, 1845, died at his home in Rock Rapids, Iowa, February 4, after 20 years of invalidism, aged 82.

Emmett E. Dixon, M.D. Atlanta (Ga.) Medical College, 1867, died at his home in Gainesville, Ga., February 1, after an illness of several weeks, from Bright's disease, aged 55.

Charles A. Mahneke, M.D. University of Berlin, Germany, 1866, died at Appleton, Wis., January 28, after an illness of three weeks, from sepsis following an operation, aged 55.

Franklin A. Gardner, M.D. New York Homeopathic Medical College and Hospital, 1882, died at his residence in Washington, D. C., February 13, from typhoid fever, aged 45.

George H. Gilbert, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1874, of Cleveland, died suddenly at a drug store in that city, February 9, from heart disease.

Jacob Burger, M.D. Eclectic Medical Institute, Cincinnati, 1856, died at his home in Franklin Square, Ohio, from paralysis, January 31, after an illness of two days, aged 75.

John P. Agnew, M.D. University of Pennsylvania, Philadelphia, 1864, who retired from practice in 1883, died at his home in Philadelphia, February 5, aged 69.

Lucian H. Shepherd, M.D. College of Medicine, Syracuse (N. Y.) University, 1895, died at his home in Oswego, N. Y., January 25, from typhoid fever, aged 37.

Morrill Wyman, M.D. Harvard University Medical School, Boston, 1837, died at his home in Cambridge, Mass., January 30, after an illness of five days, aged 90.

Lucien W. Curtis, M.D. New York University, 1848, of Southbridge, Mass., died in Worcester, January 30, from shock a day after an accident.

John R. Burton, M.D. College of Physicians and Surgeons, New York City, 1848, died at his home in Valdosta, Ga., February 7, aged 78.

Samuel Gray, M.D. University of Maryland, Baltimore, 1858, died from paralysis at his home in Laurel, Md., January 30, aged 72.

Marbury Brewer, M.D. University of Maryland, Baltimore, 1850, died at his home in Baltimore, January 24, from heart disease, aged 72.

Burdett A. Terrett, M.D. Tulane University, New Orleans, 1900, died at his home in Natchitoches, La., January 23, after a short illness.

John Ash, M.D. Philadelphia College of Medicine and Surgery, 1851, died at his home in Brighton, Ill., January 31, aged 84.

William S. Dempsey, M.D. Medical College of Ohio, Cincinnati, 1874, died at his home in Richmond, Ind., February 7, aged 64.

David M. Browder, M.D. Eclectic Medical Institute, Cincinnati, 1885, died at his home in Sweetwater, Tenn., February 5.

Book Notices.

THE NOSE AND THROAT IN MEDICAL HISTORY. By Jonathan Wright, M.D., Brooklyn, N. Y. 8vo. Cloth. Pp. 250. Ten Illustrations. Price, $2.00 net. St. Louis, Mo.: The Laryngoscope Co.

This is a valuable addition to the early history of medicine. It is written interestingly, and the data is so given as to allow the reader to draw his own conclusions, beside giving the author's own views regarding them. Beginning as it does with the earliest known inscriptions and manuscripts, it continues through the various evolutionary stages of the science of medicine down to the present time. While the author professedly deals specially with the history of medicine as related to the nose and throat, there are, nevertheless, numerous references which make the book interesting to the general practitioner. It would be hard to believe that the science of medicine should have sprung spasmodically to the high degree of excellence in which we find it, as described by Hippocrates, without having passed through a long, evolutionary process. The author's references to the early Egyptian physicians, together with our general knowledge of the influence exerted by the Egyptians over the Greeks in other lines, lead us to believe that the evolution was not lacking after all. Doubtless in the destruction of the great Alexandrian library which the author describes in detail many early and valuable treatises on medicine were destroyed.

However, the fame of Hippocrates is not to be belittled. "Never since in the history of the world have there existed in the space of one man's life so many men whose fame still shines in mortal records and whose words still influence the thoughts of men. . . . None can say that the great name of Hippocrates stands less illustrious on the roll of medical science than does that of Socrates in philosophy, of Phidias in sculpture, of Demosthenes in oratory, of Thucydides in history, or of Aristotle in science." Considering his work, "all his writings . . . testify to the persistence with which he studied the symptomatology rather than the pharmacology of disease." As to his love of truth, a quotation from Plutarch says that "he confessed publicly that he had mistaken the nature of the sutures of the skull, and has left an acknowledgment under his own hand; for he thought it very unworthy of a man of his profession not to discover where he was in the wrong, seeing that others might suffer and err by his authority."

In the description of Galen and his time, we are reminded of our great indebtedness to this tireless worker for our knowledge of anatomy. While "it would have been manifestly impossible for any one man to have himself originated the discovery of one-tenth part of the new anatomical facts as met with in Galen for the first time," nevertheless he is the real author of many of them.

In this book we read how fanaticism, superstition and mysticism are in continual conflict with the scientific advancement of medicine, and proper tribute is paid to the men whose lives were spent in the promotion and advancement of medicine as a profession. The various discoveries, the correction of errors, the invention of various instruments and devices to aid the diagnosis and treatment of disease, all are aptly described. Through it all we see how the truth regarding the practice of medicine gradually emerges through the enshadowing clouds until it reaches its present stage of progress toward perfection.

Those who have not given the subject special attention will be interested to learn that the work of laryngologists began before the times of Hippocrates, and that the three to six weeks' courses devoted to this subject by many of the post-graduate schools are hardly sufficient to make full-fledged specialists. Hippocrates describes an excellent treatment for fracture of the nose by raising the bones and inserting hollow wooden tubes in the nostrils to keep them in position. He also had an idea of intubation of the larynx for croup, though it is probable that he never practiced it, but his method of removing polypi, which was mentioned by Voltolini in his text-book, 1890, is one of the most striking illustrations of the absence of anything new under the sun. Indeed, Hippocrates described various methods of performing this operation, some of which are practiced at the present time.

Alcmæon, 520 B. C., by his dissections, discovered the eustachian tube. Celsus had definite views about the treatment of diphtheria and ozena, most of which have, however, been long since abandoned. Areteaus, who lived shortly before the birth of Galen, A. D. 131, wrote a very interesting chapter on diseases of the uvula, but felt helpless in the presence of diphtheria and criticised the operation of laryngotomy, which had been recommended to alleviate the dyspnea caused by the disease, though Asclepiades approved of the operation.

Galen wrote a book on the formation of the voice, and incidentally discussed the therapeutics of diphtheria.

Tracheotomy was familiar to the Egyptian practitioners of the Tenth Century. Albucasis, one of the early Egyptian surgeons, describes a cure for postnasal tumor. Fabricus, about the year A. D. 1590, recommended cauterizing ulcers in the nares through an iron canula, and Dionis, A. D., 1707, gives several illustrations of the instruments that he employed for this purpose. Fabricus Hildanus, 1646, employed a powder blower in the treatment of diseases of the throat, and when this method did not suffice, advised removal of a part of the uvula with scissors, ligature or caustic. He also gives illustrations of several instruments for applying the ligature and of forceps for the removal of nasal polypi.

So on, down through the ages, we find numerous references to nasal and laryngeal surgery and medicine; some crude, indeed, but others quite as good as some of the methods that are adopted to-day.

LIFE AND CORRESPONDENCE OF HENRY INGERSOLL BOWDITCH, by V. Y. Bowditch, A.B., M.D. In Two Volumes. Vols. I and II. Cloth. Pp. 337 and 397 Respectively. Price, $5.00 net. Boston and New York: Houghton, Mifflin & Co. 1902.

There is always a stimulus in reading the life of a great man, especially if, as in this instance, the true inner life—the man himself, his ambitions, his fear, his successes, his failures—is depicted. While Dr. H. I. Bowditch, in his time, was one of the leading physicians of Boston (he always eschewed surgery), he was better known in his early professional life as a leader among the abolitionists. He took up the anti-slavery cause at the very beginning, when it was unpopular, even in Boston, to do so, and no one was more aggressive in the cause than he. It is not to be wondered at, then, that the greater part of the book is devoted to this phase in his career, much as we might have wished it were otherwise and that more of the volumes had been given up to the medical side of his life.

The major part is in the form of private letters and extracts from his journal and diary and from unpublished manuscripts, public utterances and publications. While so much of the work is taken up with matters not of special interest to medical men as such, there is enough of that which pertains to the man as a physician to make it of medical interest also. Dr. Bowditch was lucky in being able to follow up a good grounding in medical education in this country, at Harvard, by two years of post-graduate work in Europe, most of the time in Paris. His life there is autobiographical in character, being in the form of descriptive letters and matter taken from his diary. While in Paris he was a favorite pupil of Louis, and had as fellow students Oliver Wendell Holmes, James Jackson, Jr., and Mason Warren. While in Paris he met and fell in love with an English girl, who later became his wife. This was a cause of much anxiety on the part of his father, and the conflict between duty to and respect for his father's wishes and love for the girl was a severe one and lasted for a long time, but finally ended happily for all concerned. Dr. Bowditch was greatly interested in the American Medical Association, believed in the broadening effect of its annual meetings, "and frequently spoke of the influence for good which the friendship thus formed had on his life." As a member of the Association he preached liberality in regard to the code. He was elected President of the Association in 1876, and presided at the Chicago meeting the year following. He was an early and ardent advocate of medical education of women, and did as much as anyone to put down the prejudice against their admission into the medical ranks. He was one of those who succeeded in having created the Massachusetts State Board of Health—the first of its kind, we believe—and was its first chairman. He was also a member of the first National Board of Health, created in 1879. In many other ways his works prove him to have been a public-spirited physician, unselfishly and courageously working for all that, in his opinion, would benefit his profession and the public.

A son has presented to us in a simple manner the life and work of a noble father, a man who was loved for the good he did, as well as for the nobleness of his character.

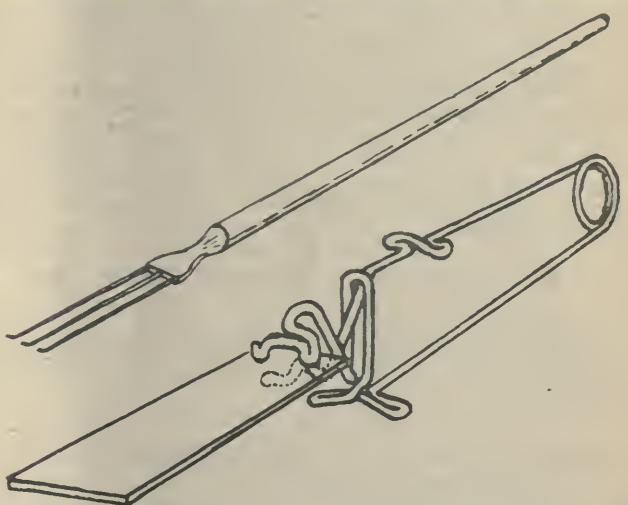
The volumes contain several excellent photographs and other illustrations.

A MANUAL OF MEDICINE. Edited by W. H. Allchin, M.D., Lond., F.R.C.P., F.R.S. Edin., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Vol. IV. Diseases of the Respiratory and of the Circulatory Systems. Cloth. Pp. 493. Price, $2.00 net. New York: The Macmillan Co. 1902.

This fourth volume of Allchin's manual contains the diseases of the respiratory and circulatory systems. The authors' names, which are a guarantee in their way of the merit of the articles, are Drs. J. Mitchell Bruce on diseases of the heart and blood vessels, Dr. Francis de Havilland Hall on diseases of the pleura, Dr. Leonard Hill on physiology of respiration and circulation, Dr. Hector MacKenzie on diseases of the lower respiratory tract, Dr. Lewis Smith on disorders of the upper respiratory tract, and the editor on disorders of the diaphragm and dropsy. While the book in its treatment of the subjects is often brief, yet the articles are of a quality that can not be criticised, and the illustrations, skiagraphs, etc., are well selected and instructive. The volume seems to us to keep up the reputation of the work as a whole to its full extent.

THE ISLE OF CONTENT, and Other Waifs of Thought. By George F. Butler. M.D. Cloth. Pp. 142. Price, $2.50. Concord, Mass.: The Erudite Press. 1902.

Dr. Butler is well known as a writer of one of the best text-books on materia medica and as a medical writer of more than usual merit, as well as the editor of a semi-popular magazine which has deservedly met with commendation from the profession and others. In this volume he has collected a number of little essays and bits of poetical prose, with one or two more lengthy contributions in verse which have appeared during the past few years. They are brought out in excellent style on a fine quality of paper with broad margins. The only criticism we want to make is that there is too much blank space in the book that we wish might have been filled with a like quality of matter.



New Instrument.

SECTION LIFTER AND SLIDE FORCEPS FOR THE PATHOLOGIC LABORATORY.

CHESTER J. STEDMAN, M.D.
ASSISTANT PATHOLOGIST, BALTIMORE MEDICAL COLLEGE.
BALTIMORE.

For the laboratory man who has five or six hundred histologic or pathologic sections to stain every day, the old method of changing the sections from dish to dish with a single needle is a rather tedious process; especially so in the case of those solutions in which the sections may remain for only a few moments. With such solutions the stainer must either take time to run his sections through in lots of half a dozen or run the risk of exposing some of them to overaction of the solution by putting some fifty or sixty in the dish at one time, and depending on his ability to capture them all with his single needle before some of them are spoiled by the solution.

After considerable experience in staining up sections for large classes, it seems to me that the work can be greatly facilitated by using a lifter with several points instead of one. With this idea in mind I have devised a little instrument, which consists, practically, of three needles mounted in one handle. With an instrument of this kind sections can be handled much more rapidly and accurately than by the old single needle

method. Fifty sections can be run through a solution at one time quite as safely and quickly as ten could be handled with a single needle. These statements are founded on practical experience, and I trust that other laboratory men may find this little instrument a useful addition to their staining outfit.

The other instrument is a slide holder, or forceps, intended for holding microscope slides during the staining process. The chief drawback connected with all other slide holders which I have seen lies in the fact that, at some point or other, the wire from which the holder is made comes in contact with the edge of the slide, and thereby acts as a conductor which the staining fluid readily follows over the edge, to drop down on whatever may lie below. Such slide holders not only waste staining fluid, but are very objectionable from the standpoint of cleanliness. More than that, most of the holders are structurally deficient in that they do not hold the slide perfectly level.

In view of the foregoing facts I have worked out a slide holder which I believe to be a decided improvement over anything of the kind heretofore in use. It is cheap, consisting of a single piece of bent wire; it holds the slide perfectly level when resting on the table; and, best of all, the wire in no situation lies in contact with the edge of the slide, to act as a conductor for the staining fluid. The slide is held firmly between four points of wire, two above and two below, and with ordinary care in handling the cohesive properties of the staining fluid will effectually prevent its passage over the edge of the slide.

Miscellany.

All That Is Necessary.—The American Association for the Advancement of Science says the following lines are all that is necessary for the physician to learn in order to prescribe in the metric system: 1,000 milligrams make 1 gram. 1,000 grams or cubic centimeters make 1 kilo or liter. 65 milligrams make 1 grain. 15½ grains make 1 gram. 31 grams make 1 ounce, troy.—*Med. Review.*

The American Pharmaceutical Association, at its fiftieth annual meeting in Philadelphia in September, passed a resolution that hereafter the metric system of weights and measures should be used in all papers read before the association and that pharmaceutic journals should be requested to use the same system wherever practicable in their publications. Another resolution passed stated that it is desirable that the pharmacist discourage the refilling of prescriptions unless ordered to do so by the prescriber. After a discussion in the scientific section relative to the advisability of retaining methyl salicylate, artificial, in the pharmacopeia, it was decided that it should be retained, but that it should not be named synthetic oil of wintergreen. It was also decided that oil of wintergreen obtained from *Gaultheria procumbens* should be known as "oil of wintergreen" and that oil of *Betula lenta* under its proper title should be introduced into the pharmacopeia. We quote the following from the address of the retiring president, Henry M. Whelpley (the complete report appears in the *Pharmaceutical Era* of September 18): "I hope that an increasing number of American Pharmaceutical Association members will attend the coming annual meetings of the American Medical Association. We are not likely to overestimate the importance of conjoint work in the two callings which go to make up the healing art and the art of preparing healing appliances. The more we mingle with each other the better we will understand the feelings that actuate those who are striving for the common good of medicine and pharmacy.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

THE NEXT PHARMACOPEIA.

ALBANY, TEXAS, Feb. 9, 1903.

To the Editor:—Will you kindly inform me when the new edition of the U. S. Pharmacopeia will be issued? If you can do so through your columns please give me the name of the publisher.

H. L. WILDER.

ANS.—The revision of 1890 appeared in 1893, published by the committee on revision, through P. Blakiston's Son & Co., Philadelphia, at $2.50. The revision of 1900 is looked for before the end of the present year.

MISSISSIPPI RIVER EXCURSION TO NEW ORLEANS.

PHILADELPHIA, Feb. 6, 1903.

To the Editor:—I wish to ask if it is likely that any arrangements will be made to go down the Mississippi river by steamer. This is a trip that I have for many years desired to take, and now seems the opportunity to take it while going to New Orleans to attend the Association meeting in May. My idea would be to go down the Mississippi river by steamer, either from St. Louis or Memphis; but I would wish to return to Philadelphia by all rail. I will be pleased to avail myself of the information that you will gather for the profession, so far as it will go to meet my plans; further than that I will make independent inquiries.

C. F. TAYLOR

NOTE.—This suggestion is worth the consideration of those interested.

MEDICAL PRACTICE QUERIES.

OTTOSEN, IOWA, Feb. 10, 1903.

To the Editor:—Please inform me as to the requirements to practice medicine in South Dakota and Colorado; also the names of the secretaries of each of the above state boards, with addresses.

W. M. SHIPLEY.

ANS.—In South Dakota an approved diploma, and evidence of good habits and moral character are required. The secretary of the board of examiners is Dr. T. W. Moffitt, Deadwood. In Colorado an approved diploma or an examination is required. The secretary of the board is Dr. S. D. Van Meter, Denver. A new law stricter in its requirements is before the legislature, and has passed the lower house.

GRAND LEDGE, MICH., Feb. 10, 1902.

To the Editor:—Can you inform me as to the necessary qualifications for a physician to practice in Oklahoma, as to board of registration, etc.? E. M. PAINE.

ANS.—An approved diploma is required. Address Dr. T. E. Cowdrick, Enid, Okla., president of the board of health.

State Boards of Registration.

The District of Columbia Board of Medical Supervisors held an examination at Washington, D. C., January 8, 1903. Dr. Wm. C. Woodward, secretary, reports as follows: Number of subjects examined in, 17; total number of written questions, 80; percentage required to pass, 75; partly oral and partly written examination; total examined, 11; passed, 10; failed, 1.

PASSED.

Candidate.	Sch. of Pract.	College.	Year Grad.	Per Cent.

Medical Organization.

Progress in Nebraska.

Dr. A. D. Wilkinson, secretary of the Nebraska State Medical Society, writes that already thirty-two counties have reorganized and adopted the Constitution and By-laws for

County Societies, and ten or fifteen more counties are expected to be in line within the next few weeks. On February 10 the Omaha Medical Society reorganized as the Douglas County Medical Society and adopted the official constitution and by-laws.

Fillmore County (Neb.) Medical Society.

On January 28, at Geneva, this society was reorganized on the lines suggested by the American Medical Association, with the following officers: Dr. B. B. Mozee, Geneva, president; Drs. John W. Archard, Grafton, vice-president, and Dr. C. F. Morsman, Strang, secretary and treasurer.

Belmont County (Ohio) Medical Society.

At the January 7 meeting, held in Bellaire, Dr. James C. M. Floyd, Steubenville, state councilor, presented the subject of reorganization, after which the society, after making slight amendments to meet local needs, unanimously adopted the constitution and by-laws suggested for county societies by the American Medical Association. The following officers were elected: President, Dr. James G. Wilson, Colerain; vice-president, Dr. Arlington W. Diven, Martin's Ferry; treasurer, Dr. Alfred C. Beetham, Bellaire; secretary, Dr. James S. McClellan, Bellaire; censors, Drs. James O. Howells, Bridgeport, Joseph W. Cooper, Bellaire, and J. C. Archer; delegate to the Ohio State Medical Society, Dr. J. Park West, Bellaire, and alternate, Dr. Brady O'N. Williams, Martin's Ferry.

Societies.

Huntington (W. Va.) Medical Society.—This society met, January 8, and elected Dr. Thomas J. Prichard, president; Dr. Archibald Crary, vice-president; Dr. Isaac R. La Sage, treasurer, and Dr. Thomas W. Moore, secretary.

Chicago Medical Society (Evanston Branch).—This branch society was organized, January 15, by Dr. William A. Evans, president of the county society. Dr. William L. Ballenger was elected president, and Dr. Ernest L. McEwen, secretary.

Vermilion County (Ill.) Medical Society.—At the regular meeting in Danville, February 9, the certificate of the Illinois State Medical Society, accepting the Vermilion County Society as a regularly-affiliated branch, was received and ordered framed.

Gloucester County (N. J.) Medical Society.—At the annual meeting, January 15, Dr. E. Mortimer Duffield, Glassboro, was elected president; Dr. William Brewer, Woodbury, vice-president, and Dr. George E. Reading, Woodbury, secretary and treasurer.

Duval County (Fla.) Medical Society.—At the annual meeting in Jacksonville, January 17, Dr. Sheldon A. Morris was elected president; Dr. John H. Douglas, vice-president; Dr Jay H. Durkee, secretary and treasurer, and Dr. Columbus Drew, corresponding secretary.

Harrisburg (Pa.) Academy of Medicine.—At the annual meeting, January 30, the following officers were elected: President, Dr. John B. McAlister; vice-presidents, Drs. William J. Middleton, Steelton, and Martin L. Walford; secretary, Dr. Thomas S. Blair, and treasurer, Dr. E. Harold James.

Manila (P. I.) Medical Society.—At the annual meeting, January 6, the following officers were elected: Dr. J. M. Donelan, president, and Dr. W. E. Musgrave, secretary-treasurer. The councilors of the society are as follows: Drs. Paul C. Freer, John R. McDill, John Maye, H. W. Yemans and Frank S. Bourns.

Harlan County (Neb.) Medical Society.—An auxiliary of the state and national medical societies was organized at Orleans, January 21. Dr. William H. Banwell, Orleans, was elected president; Dr. Samuel M. Baker, Alma, vice-president; Dr. Campbell, secretary, and Dr. Dickson R. Waggoner, Stamford, treasurer.

Medical Society of the Missouri Valley.—The spring meeting of this association will be held in Council Bluffs, Iowa, March 19 and 20. The membership of this society includes Iowa, Nebraska, Missouri, Kansas, North and South Dakota physicians. Dr. Charles Wood Fassett, St. Joseph, Mo., is the secretary.

Atlantic County (N. J.) Medical Society.—At the annual meeting held in February, the following officers were elected: President, Dr. Theodore Senseman of Atlantic City; vice-president, Dr. Edmund A. Madden, Absecon; secretary and treasurer, Dr. Edward Guion, Atlantic City, and reporter, Dr. A. Burton Shimer, Atlantic City.

Chautauqua County (N. Y.) Medical Association.—The second annual meeting was held in Jamestown, January 20. Dr. Orrin C. Shaw, Cassadaga, was elected president; Drs. Era M. Scofield, Jamestown, first vice-president; Dr. Vacil D. Bozovsky, second vice-president, and Dr. Henry A. Eastman, Jamestown, secretary and treasurer.

Dawson County (Neb.) Medical Society.—A meeting of the physicians of the county was held at Gothenburg, January 23, at which a medical society was organized with the following officers: President, Dr. Edwin O. Boardman; vice-president, Dr. Barton B. Baker, Lexington, and secretary and treasurer, Dr. P. Emmet Plumb, Gothenburg.

Greene County (Ark.) Medical Society.—At the annual meeting, February 2, held at Paragould, Dr. James W. Johnson, Paragould, was elected president; Dr. E. L. Kennedy, Marmaduke, vice-president, and Dr. Adolphus G. Clyne, Bethel, was re-elected secretary and treasurer. The new constitution and by-laws of the Arkansas Medical Society were adopted.

Chatham County (Ga.) Medical Society.—At the annual meeting held in Savannah, January 7, the following officers were elected: Dr. Marion X. Corbin, president; Drs. J. Lawton Hiers, and George R. White, vice-presidents; Dr. J. Walter Williams, treasurer; Dr. Ralph M. Thomson, recording secretary; Dr. Gustaf H. Johnson, corresponding secretary, and Dr. Elton S. Osborne, librarian, all of Savannah.

Harrison County (W. Va.) Medical Society.—At the regular meeting, held at Clarksburg, February 4, the constitution and by-laws recommended by the American Medical Association and the West Virginia Medical Association for county societies was adopted. The following officers were elected: President, Dr. Thomas M. Hood; vice-president, Dr. S. L. Mason; secretary, Dr. Chester R. Ogden, and treasurer, Dr. Robert A. Haynes, all of Clarksburg.

Douglas County (Omaha) Medical Society.—At the annual meeting in Omaha, January 13, Dr. Harry M. McClanahan, Omaha, member of the House of Delegates of the American Medical Association, presented the general plan of reorganization suggested by that body, and a general discussion of the subject followed. Dr. William H. Christie, Omaha, was elected president; Dr. H. P. Hamilton, Omaha, first vice-president; Dr. F. W. Faulk, South Omaha, second vice-president; Dr. Joseph M. Aikin, Omaha, secretary, and Dr. Millard Langfeld, Omaha, treasurer.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, held Jan. 2, 1903.

The President, Dr. John M. Fisher, in the Chair.

Fibromyoma of the Round Ligament.

DR. MELVIN M. FRANKLIN reported a case of fibromyoma of the round ligament in a patient aged 29. The tumor, which was about the size of a walnut, was situated in the inguinal canal, just without the internal abdominal ring. Pressure on the growth caused considerable pain and nausea. The tenderness was markedly increased during menstruation. The periods had always been normal and she suffered with dysmenorrhea.

DISCUSSION.

DR. JOHN C. DACOSTA did not remember having ever had such a case. He had two cases of pure fibroma of the broad ligament.

DR. W. KRUSEN said that such a rare tumor is interesting from a diagnostic standpoint because it may be mistaken for lipoma, ovarian or intestinal hernia or enlarged lymph glands. Another interesting point is that during pregnancy these tumors often increase in size and also during menstruation. This probably indicates their relation to the uterus. The most frequent situation is on the right side.

DR. E. E. MONTGOMERY said that tumors of the round ligament are very rare. We can readily realize that in the round ligament, which contains both muscular structure and blood vessels, there is ample material for the development of this class of tumors, whether we assign their origin to the muscular structure of the round ligament itself or to the muscular wall of the blood vessels. Their infrequency in the round ligament

is readily explained by the fact that the structure is rarely subject to injury.

DR. JOHN M. FISHER said that Dr. Clark, a few years ago, reported a case of coincident sarcoma of the uterus with fibromyoma of the round ligament, demonstrating the importance of making a microscopic examination.

Preliminary Report of an Operation for Abdominal Pregnancy of Twenty-One Months' Standing.

DR. C. P. NOBLE reported the clinical history of this patient, who was a multipara, 30 years of age. She missed her menstrual period in March, 1901. Two weeks later she was taken with a sharp, agonizing pain in the right iliac region, diagnosed by her physician as appendicitis, and was in bed for three weeks. Two months subsequent to the date of expected labor she consulted a gynecologic dispensary where a diagnosis of "tumor" was made, and medicine given "to dissolve it." She remained under this treatment for three months. She was finally sent to the Kensington Hospital for women, Philadelphia, with a diagnosis of fibroid. Dr. Noble made a presumptive diagnosis of abdominal pregnancy and verified the diagnosis by an abdominal section. The fetus occupied the left side of the abdomen, extending into the pelvis; the uterus was pushed to the right and elevated. The round ligament and tube ran over the face of the "tumor." The sac was so thick that it was impossible to outline the fetal parts. The ovarian and uterine vessels on the involved side were ligated, the fetus and sac elevated out of the pelvis and the lower end of the mass turned upward. By getting at the mesentery vessels from below and behind it was possible to control the bleeding without difficulty. The uterus was not removed. The patient made a satisfactory recovery.

DR. E. E. MONTGOMERY spoke as follows: The case presented by Dr. Noble is one of very great interest from a diagnostic standpoint. Everyone who has had an opportunity of observing a large number of patients appreciate the frequency of cases which will come under his observation, where it is difficult to determine whether he has to deal with a pregnancy, fibroid tumor or other abdominal growths. I remember a case which came under my observation years ago at Jefferson Hospital of a woman who had gone fifteen months from the time she conceived without delivery. Two months subsequent to her conception she had what she supposed to be an abortion. There was a discharge of clots of blood and she suffered great pain. A bloody discharge continued for some weeks subsequently. A few months later she recognized fetal life, and again became reconciled to the fact that she was pregnant. At the completion of what should have been the normal period of gestation, however, labor did not occur. At the time the patient came under our observation she presented a tumor which filled the abdomen to nearly the size of a woman at full term of pregnancy. Examination revealed fluctuation while percussion over the tumor gave resonance. On examination per vaginam the uterus could be recognized situated in front and somewhat to the left of the mass. While a portion of the tumor felt solid, one was unable to palpate and recognize distinctly its parts. The history of the case and the conditions present led me to form the diagnosis of ectopic gestation, in which the fetus had undergone maceration and decomposition, and the resonance in the sac was the result of the gas thus formed. On opening the abdomen we found a condition similar to that which I had expected. The uterus was in front of the mass, the tumor occupied the abdomen above and the wall of this tumor was made up of a membranous sac to which the placenta was attached at the upper part. The placenta was without vitality, was easily pulled off with the portion of the sac to which it was attached and without hemorrhage. The entire lining membrane of the sac was covered with macerated material. With the removal of the fetus, the sac was thoroughly cleansed, stitched to the abdominal walls and packed with iodoform gauze. The intestines were closely adherent to it and formed a part of the sac wall, so it was impossible to attempt its removal. The convalescence was slow; patient finally recovered.

The second case which comes to my mind is that of a wife of a physician in the upper part of the state. On examination a tumor was recognized to one side of the uterus, which filled up the pelvis. The history and the examination of the case led me to unhesitatingly pronounce it a fibroid tumor. It had been in existence for two years. The patient was unwilling to submit to operation, became pregnant, and gave birth to a child without interference to the sac, and, so far as I know, she still carries it.

Another patient treated at the Jefferson Hospital is of diagnostic interest. She had a mass which had been pronounced pregnancy by several physicians. One physician, an eminent gynecologist in the city, pronounced this a pregnancy and saw the patient several times during the supposed gestation. The woman, however, did not attain to the size she supposed to be proper, and the time passed beyond which labor should occur. She was brought to the hospital and even then the growth was considered a delayed pregnancy. There was found situated in the vagina a mass the size of a fetal head, so divided as to lead to the belief that the fontanelles could be felt between the masses. On examination over the abdomen a mass could be pushed away and felt to rebound against the hand. This was supposed to be the body of the fetus. In examining this patient, however, I felt satisfied from the surfaces intervening between the vaginal mass and the finger that it could not be within the uterus. If it was a fetus it was evidently situated anterior to that organ. I hardly believed that we would likely find an ectopic gestation in that situation. The sensation of free movement of the upper part was due to the fact that the tumor was connected with the fundus of the uterus by a rather thick, yet flexible, pedicle, which permitted the fundus to be pushed away and to return against the hand. The latter was favored by a considerable amount of ascites. As soon as the abdomen was opened a considerable quantity of fluid was discharged and the mass projected into the wound. A number of fibroid tumors occupied the body of the uterus.

I think these cases indicate the difficulty in diagnosis which will sometimes lead the patient to go for some length of time under the observation of careful men and they be mistaken for other conditions.

DR. W. KRUSEN said: Dr. Noble's interesting case recalls a postmortem which I had in 1893 while a resident at Jefferson Hospital. I had the opportunity, through the courtesy of Dr. Hearn, of making a postmortem in the case of a patient in the northern part of this city. The abdomen had been gradually increasing in size for ten months and no menstruation had been present for that time. The patient had been seen before in consultation by the late Professor Parvin and the condition was such that operation was thought inadvisable. The patient died, and on postmortem there was found within the abdominal cavity a full-sized fetus, larger than the size of a baby a month old. A hematoma occupied the position of the uterus. The head of the fetus was directly under the spleen. The case illustrates the tolerance of the peritoneum to the development of the fetus. This was a case in which undoubtedly rupture had occurred. The hemorrhage had not been such as to produce death and the fetus had gone on to full development, weighing over ten pounds. The specimen is now in the museum of the Jefferson Hospital.

The very interesting and perplexing question to the surgeon is the treatment of the live placenta in cases of ectopic gestation. I have had an opportunity in two cases of having to contend with this difficulty.

DR. C. P. NOBLE in closing the discussion, said: The point raised by Dr. Krusen is of course the crucial one, how to deal with the hemorrhage. These cases are so rare that there are very few of us who have the opportunity to acquire views from practice. This is the first full term pregnancy of this kind that I have ever seen. I have operated on nearly a hundred cases of ectopic pregnancy, but this is the first one advanced beyond the fourth month.

I think it is best to enucleate the whole sac provided one can do preliminary ligation. If the placenta is attached to the intestines we know that we can not do preliminary ligation. On the other hand, if the placenta is in the pelvis we know perfectly well how to deal with the ovarian and uterine arteries

or with the anterior branch of the internal iliac. I should prefer to enucleate the sac under those circumstances. In a case having its blood supply from the mesenteric vessels my own action would be to pack the sac with gauze and leave it.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Cinnamon.

The oil of cinnamon in aqueous solution, according to the *Med. World*, is a splendid local antiseptic and disinfectant. It is recommended as a substitute for corrosive sublimate, as an application to prevent suppuration in recent wounds where stitches have been taken. The points in favor of its use are that it is cleanly, non-toxic and a cheap dressing. It is also used as a douche after parturition when a douche is indicated. Three or four drops of the oil may be added to two quarts of warm water and used as long as there is odor to the lochia.

Shoemaker recommends cinnamon in finely-powdered form, given in doses of one to one and a half drams, as an efficient remedy in acute dysentery. It has some hemostatic properties and is employed in the form of an infusion in milk or the oil may be given on sugar. In the palliative treatment of carcinoma of the stomach it is recommended that 10 or 12 ounces of the bark be placed in three quarts of water and boiled down to one quart, decanted without filtering. One pint of the mixture should be drunk every 24 hours.

In gonorrhea it may be used as follows:

℞.	Olei cinnamomi	m. i-iii	06-20
	Liq. petrolati	ʒi 30	

M. Sig.: Cleanse the urethra with dilute hydrogen dioxid and inject the cinnamon solution. One drop of the oil of cinnamon to the ounce should be used the first day, gradually increasing to three drops.

As an antiseptic dressing in the form of an ointment the following have been recommended by M. Championniére:

℞.	Retinol	ʒix	35
	Ceri (sterilized)	ʒiii	12
	Cinnamol	m. viiss	50

M. Sig.: Apply locally.

Retinol is a product of the destructive distillation of resin and is frequently employed as a solvent for different preparations as iodol, camphor, cocain, codein, creosote, etc. Cinnamol, according to Shoemaker, is a freshly-distilled essence of cinnamon.

℞.	Cinnamol	m. viiss	50
	Ceri steril.	ʒiii 12	
	Beta-naphthol	gr. viii	50
	Retinol	ʒix 35	

M. Fiat unguentum. Sig.: Apply locally; or:

℞.	Ess. geranii	m. xv	1
	Ess. cinnamomi	m. viii	50
	Retinol	ʒiss 45	

M. Sig.: To be applied locally; or:

℞.	Ess. thymi	m. xii	75
	Ess. geranii	m. xii	75
	Retinol	ʒiss 45	

M. Sig.: Apply locally.

Acute Coryza.

Sternberg, in an abstract in the *Month. Encyc. of Pract. Med.*, calls attention to a simple treatment which is a revival of an old method. It consists in eliminating liquids from the diet for twenty-four hours in order to dry up the secretions and relieve the congestion in the head, nose, conjunctiva and the irritating discharge from the nose. If the treatment is continued for two days the coryza will usually be brought to an end, and it will not usually be followed by a cough. The treatment is regarded as a prophylactic against otitis media or the extension of inflammation into the adjacent nasal cavities.

The treatment must be begun early in order to make it a success. The presence of fever is no contraindication to the treatment, but it should not be carried out when chronic nephritis is present.

Dandruff.

The following outline of treatment is recommended by *N. Y. Med. Jour.* in the treatment of dandruff:

℞.	Olei bergamot	gtt. ii	12
	Ung. hydrarg. oxidi rubri	ʒiv 15	
	Adipis benzoinati	ʒiss 45	

M. Fiat unguentum. Sig.: Apply locally; or:

℞.	Sodii boratis	ʒii	8
	Glycerini	ʒiii	12
	Aquæ q. s. ad	ʒv	150

M. Fiat lotio. Sig.: Apply locally.

Where there is some constitutional disturbance the following mixture may be employed:

℞.	Vini ferri	ʒiss	45
	Liq. potassii arsenitis	ʒi	4
	Syr. simplicis	ʒiii	12
	Aquæ q. s. ad	ʒiv	120

M. Fiat mistura. Sig.: One teaspoonful to be taken after each meal.

Typhoid Fever.

W. R. Perry, in an article in the *Amer. Pract. and News*, states that he has obtained unusually good results from the use of the following antiseptic combination:

℞.	Tinct. iodi	ʒiss	6
	Acidi carbol.	ʒss	2
	Spts. chloroformi	ʒii	8

M. Sig.: Two to four drops every three or four hours.

Dysphagia in Acute Anginas.

Le Prog. Med. recommends the following to relieve the pain in swallowing in the acute anginas:

℞.	Pulv. talci		
	Pulv. acid borici, āā	gr. xlv	3
	Orthoformi	gr. xv	1
	Cocainæ hyd.	gr. 3/4	05
	Pulv. menthol	gr. 1/3	02

M. Fiat pulvis. Sig.: A small amount to be insufflated into the throat through a glass tube just before eating.

[The foregoing combination is of service in any condition where disease of the throat or larynx is accompanied by pain on swallowing food. But it should be prescribed and used strictly under the care of the physician on account of the orthoform and cocain it contains.]

Croup.

L. Lozansky, in *Merck's Archives*, recommends the use of creosotal in croup, measles, and whooping cough. He usually begins with large doses and continues with reduced doses after apyrexia sets in, in order to prevent relapse. The following formula is employed by him:

℞.	Infusi ipecac.	ʒiss-ʒiii	45-90
	Sol. ammon. anis.	m. xv-xxiv	1-1 65
	Creosotal	m. xlv-lxx	3-5
	Syr. senegæ	ʒiv	15

M. Sig.: One teaspoonful every half hour for four doses, then every hour, and finally every three hours. When the temperature ranges high the following combination is recommended:

℞.	Sodii salicylatis	gr. xv-xxx	1-2
	Creosotal	m. xlv-lxx	3-5
	Emuls. amygd.	ʒiii	90
	Syr. ipecac.	ʒiv	15

M. Sig.: One teaspoonful every half hour for four doses, then every hour, gradually increasing the interval.

Clinical Use of the Iodids.

Wild, in an abstract in the *Internat. Med. Mag.*, states that both clinically and experimentally the sodium salt has proved less toxic than the potassium. He states that the two chief objections to the potassium salt are the liability to cause iodism and the marked depression it produces.

The sodium salt should be substituted when symptoms of iodism make their appearance, otherwise the potassium should

be stopped. He regards the depressing effect of the potassium to be overdrawn as ordinary food contains a considerable amount of the potash, especially the vegetable diet. To counterbalance the amount of potassium, the vegetable portion of the patient's diet can be cut down, and milk, eggs, fish and meat added.

Urethritis.

The following combinations are recommended by Brunton in the treatment of gonorrheal urethritis:

℞.	Calaminæ prep.	℥ii	8
	Zinci oxidi	℥ii	8
	Liq. plumbi subacetatis	℥i	4
	Glycerini	℥i	4
	Aq. calcis q. s. ad	℥i	30

M. Fiat mistura. Sig.: To be used locally as an injection.

[It will be noted that the amount of zinc and lead preparations is large.]

Or:

℞.	Zinci sulph.	gr. i	06
	Zinci acctatis	gr. i	06
	Tinct. catechu	m. x	65
	Ext. opii fluidi	℥ss	2
	Aq. destil. q. s. ad	℥i	30

M. Sig.: As an injection; or:

℞.	Zinci sulphocarbol.	gr. iv	25
	Aq. destil. q. s. ad	℥i	30

M. Sig.: To be used as an injection.

Nocturnal Incontinence of Urine.

The following, according to an abstract in the *N. Y. Med. Jour.*, is recommended in the treatment of nocturnal enuresis:

℞.	Syr. belladonnæ	℥i	30
	Antipyrini	℥iiss	14
	Syr. tolutani	℥iss	45

M. Sig.: One teaspoonful morning and evening. Increase the dose to two teaspoonfuls if the incontinence persists.

The foregoing, according to the author, is Trousseau's formula, to which is added antipyrin. The following, containing camphor and ammonium valerianate, is also recommended:

℞.	Ext. belladonnæ	gr. 1/6	01
	Camph. bromidi	gr. iss	09
	Ammon. valerianatis	gr. 3/4	05

M. Ft. pil. No. i. Sig.: One such to be taken at bedtime; or:

℞.	Ext. rhois arom.	gr. xxxviiss	2 50
	Ammon. valer.	gr. x	65
	Syr. menthæ	℥v	150

M. Sig.: Two teaspoonfuls morning and evening; or:

℞.	Tinct. rhois rad.	℥ii	8
	Calcii glycerophos.	gr. xxiiss	1 50
	Ferri glycerophos.	gr. xxiiss	1 50
	Syr. pruni virg.	℥x	300

M. Sig.: One dessertspoonful on rising and at bedtime.

F. T. Hopkins, in the same periodical, states that the treatment in debilitated children is a general tonic one, consisting of strychnia, arsenic, cod-liver oil, good food, cold sponging and static electricity. The employment of atropin gr. 1/100 (.0006) to gr. 1/75 (.0008), or belladonna gr. 1/4 (.015) to gr. 1/2 (.03) of the extract is advised by him.

He also recommends the passing of sounds. Any disturbance of the digestive tract should be corrected, and where constipation exists, forcible dilatation of the sphincter ani is recommended. Proper exercise should be prescribed, and the patient should be aroused at eleven o'clock at night to urinate. Any constitutional disturbance such as syphilis, tuberculosis and diabetes should be properly treated.

Brunton states, in the treatment of incontinence of urine, that we must consider the action of two different organs, the sphincter at the neck of the bladder and the fundus of the bladder, the one tends to hold the urine in the bladder and the other tends to expel the urine, so that if the sphincter is insufficiently stimulated it will remain more or less lax, and consequently will permit the urine to run out. Stimulating this sphincter, then, will stop the incontinence. Belladonna, according to him, lessens the irritability of the fundus without affecting the sphincter, so the expulsive tendency is lessened and the incontinence is frequently cured. The preparation must be pushed to its limit, as noted by the dilated pupil and the dryness of the mouth. Cantharides is also recommended by him, as it tends to stimulate both the fundus and the sphincter of the bladder.

Medicolegal.

What Physician Making Examination May Testify To.—There was some objection urged to the evidence of a physician in the personal injury case of Meeks vs. the Ohio River Railway Company because he testified as to what the party suing and her attending physician told him. He was not being strictly examined as an expert, but was being interrogated with regard to a personal examination made by himself as to the condition of the party suing. Of course, says the Supreme Court of Appeals of West Virginia, it was improper for him to state to the jury what the party suing or her attending physician told him as to her condition. But he had the right, being a physician, to testify as to his personal examination, made in the manner in which physicians usually diagnose a case; and this is not only by actual examination of the organs and limbs of the patient, but inquiry as to the symptoms, pains and otherwise. Therefore, the jury was properly instructed to disregard as independent evidence the statement made by the party suing and her attending physician to the witness, but there was no error in permitting the opinion of the witness, together with his sources of knowledge, to go to the jury, to be considered by them.

Competent Evidence of Physician's Account.—The case, taken to the Supreme Judicial Court of Massachusetts, of Mayberry vs. Holbrook was brought by a physician to recover for 126 professional calls. At the trial, with his books before him, he testified on his examination in chief that he had made that number of calls. On cross-examination he testified that he did not keep the run of these calls in his memory, and that without looking at the books he could not tell about their number. It did not appear that the books were put in evidence. The party sued denied that any calls were made, and asked a ruling that, on all the evidence, the physician could not recover. The judge refused so to rule. On the point involved, he instructed the jury: "I am reminded by counsel that he does not desire to admit that the services were rendered as charged, and it is said that the plaintiff [the physician] having testified that he could not now state from memory, independent of his books, that he did render services as charged in the bill, but he states that he did render them as charged in the bill; he also states that in making that he relies on his books. He does not state that the books refresh his recollection, so that he can now have a distinct recollection of all those items, but that is not necessary. If the books enable him to say, on his oath, that the fact was as the books have it, that would be sufficient . . . if, from the plaintiff's method of keeping the books, he is able to say from the entries, as he inspects them, that the facts are as there entered, that is competent evidence, and it is only for you to say what its weight is." The Supreme Judicial Court holds that the instructions were correct and applicable, and overrules the exceptions of the party sued, the physician having had judgment.

Care Required — In Operation and After — Leaving Sponge—Limitations.—In the case of Gillette vs. Tucker, as it is entitled in the Supreme Court of Ohio, an action brought by the latter party, the "Syllabus by the Court" is: A surgeon and physician, employed to treat a case professionally, is under an obligation, which the law implies from the employment, to exercise the average degree of skill, care and diligence exercised by members of the same profession, practicing in the same or a similar locality, in the light of the present state of medical and surgical science; and that he will indemnify the patient against any injurious consequences which may result from his want of ordinary skill, care and attention in the execution of his employment. It is the duty of the physician and surgeon to exercise due and

ordinary skill, care and attention, not only in and about an operation which he decides to be necessary, but also, in the absence of a mutual understanding or notice to the contrary, to render such continued further care and treatment as the necessity of the case requires; and he is liable for injuries and damages which proximately result from the want of such ordinary skill, care and attention. Where the physician and surgeon so engaged operates on the patient for what (as in this case) he pronounces to be appendicitis, and neglects or carelessly forgets to remove from the abdominal cavity a sponge which he had placed therein, and closes the incision, with the sponge remaining therein, and this condition continues during his entire professional relation to the case and is present when he abandons or otherwise retires therefrom, the statute of limitations does not commence to run against a right to sue and recover on account of such want of skill, care and attention until the case has been so abandoned, or the professional relation otherwise terminated. It is stated, in the opinion, among other things, that the mere closing of the incision in question over the sponge was not the party's cause of action, if no injurious consequences followed. But if evil consequences followed, and she was injured, her cause of action accrued when her injuries occurred; and if these injuries blended and extended during the entire period the surgeon was in charge of the case, her right of action became complete when the surgeon gave up the case without performing his duty. It would be inconsistent to say that the party might sue for her injuries while the surgeon was still in charge of the case, and advising and assuring her that proper patience would witness a complete recovery. The facts in the case showed a continuous obligation so long as the relation or employment continued, and each day's failure to remove the sponge was a fresh breach of the contract implied by the law. The removal of the sponge was a part of the operation, and in this respect the surgeon left the operation uncompleted. A judgment of the Circuit Court, granting the party suing a new trial, after a verdict had been directed against her, on the ground that her cause of action was barred by the one-year statute of limitations of Ohio for actions for malpractice, is affirmed, or, more strictly speaking, left to stand, the Supreme Court being equally divided. In the dissenting opinion it is maintained that the injury was permanent and complete so far as the surgeon's agency and liability were involved when he closed the wound and did not remove the sponge. If any injury whatever ensued from delay in discovering and removing the sponge, it was merely incidental and consequential to the principal act of leaving the sponge in the abdomen when the operation was completed. Stated in slightly different language, but the same effect, the charge was that the surgeon permitted the sponge to remain in the abdomen when he closed the incision, and he permitted it to remain afterward as long as he attended her. In this way of stating the case, it is clear that the wrong inflicted was complete on the day of the operation, and the cause of action then accrued, unless the surgeon was to be held liable in another cause of action for not knowing or not discovering that the sponge was there. But this could not be, for whatever injury the party suing suffered was the result of, or consequential to, the wrong inflicted in the beginning, and hence a recovery for that would be a bar to a recovery for the other.

1. **Spinal Cocainization.**—This procedure, which has gone into disfavor to some extent, owing to the conservative views of Bier and others, is discussed by Dickinson, who points out the anatomy of the parts involved, the details of the resistance of the tissues and technic of operation. Of course, great importance must be laid on the purity of the cocain, the asepsis and technic. He considers that the method of lumbar puncture is an art, and experience is necessary. The surgeon attempting it for the first time will possibly have to make several trials before success, and then perhaps fail in the end. Generally a needle will enter jumping through the ligamentum subflavum with a sense usually appreciated by the finger, entering at a point a little less than one-quarter of an inch below and one-half inch to the right of the spinous process selected. If it passes a little too far to the right, the fibrous tissue only of the transverse process will be punctured and a sense of continuous interference felt, and perhaps no fluid flow. Once in the canal, fluid generally comes, but at times must be started by a cough or straining effort. In later operations about twice the amount is allowed to escape as is thrown in. It will take years of careful work to ascertain absolutely the possibility of harm. Cardio-respiratory phenomena are the dangers to be apprehended, and if it can be shown in time that the risk is sufficiently minimized, it will prove the true value of the method. Possibilities of the blocking of the centers of the medulla are certain, if large doses are given, but half a grain seems hardly sufficient to induce alarming symptoms in the adult. The danger of infection is an idle objection to the careful surgeon. To sterilize a solution without destroying it, the plan suggested and carried out by Van Horne of New York is to make a 2 per cent. solution in sterile water, and put 25 minims into small glass capsules. This is exposed to a temperature of 176 for four hours for four successive days, which renders the solution safe surgically and does not influence the drug effect. Idiosyncrasy is a point that must give us most concern, but it exists not only to this, but to other methods of anesthesia. Dickinson says that cocain analgesia is to be preferred to ether in all cases in which the patient will not have to be over-much mentally disturbed by the time and surroundings. No meals are lost and no metabolic changes are induced.

2. **Tachycardia.**—Morrissey defines tachycardia not as simply heart hurry, but as a species of rapid heart, depending on causes within the heart itself, or produced by other causes more or less removed from the cardiac region. There are certain peculiarities which distinguish true tachycardia from evanescent heart hurry: 1. The attack is sudden and reaches its height almost immediately. 2. The patient may or may not be entirely unconscious of the great degree of palpitation. 3. There is generally a definite period covered by the attack. 4. The reversion to the normal condition is as sudden as the onset. He does not regard temperature elevation as of any special significance. From a clinical point of view he would classify tachycardia as short and long. The first is accompanied by vertigo, epigastric distress and at times a sensation of cardiac expansion. There is no discoverable cause, and the symptoms are mainly subjective. A long attack may cover a period of years to the great distress of the patient, and it may result in death. He reports two cases which he considers typical: one produced by myocardial degeneration and another by profound shock to the nervous system. He discusses the subject of reflexes of this class at considerable length and considers that there are probably many causes from which tachycardia originates. Its pathology is not yet clear. The treatment is the treatment of the condition from which it arises or with which it is associated. He has treated cases and found relief in the use of convallaria where digitalis failed, and others where convallaria failed; so he is skeptical of its action. In the third case, which may be described as coming within the lower range of tachycardia, there was marked arterial tension with decided neurasthenic leanings. He gave bromid potassium for its sedative effect and the iodid for its action in dilating

the peripheral arterioles, reducing the tension and rendering the work of the heart less arduous. In conclusion he speaks of bradycardia and its significance, and remarks that every heart is a law unto itself and the producing of snap diagnoses in cardiac disease is to be condemned.

3. **Hemorrhagic Appendicitis.**—Jacobson reports a case with appendicular symptoms in which operation relieved the intestinal hemorrhages in the appendix, which was enlarged and decidedly inflammatory in appearance. After the operation there was more trouble. Blood expectoration continued, there were petechiæ and a hacking cough. The patient recovered under the administration of suprarenal extract. He considers the case clearly one of purpura hemorrhagica in which the first evidence was hemorrhage into the appendix. There were petechiæ of the limbs and abdomen appearing within four or five days after operation. If no subsequent symptoms had appeared the case might have been put down as one of appendicitis. In conclusion he notices the literature of similar cases.

5. **Heterophoria.**—This subject is generally discussed by Matheny, who notices the view that serious conditions, epilepsy, etc., may be entirely due to imbalance and insufficiency of the eye muscles.

6. **Maternal Impressions.**—Shelly protests against the medical endorsement in text-books of the possibility of maternal impressions. He considers it a medical anachronism which is a stigma on the profession.

9. **Perinephric Fat.**—In a note by Dr. Keen he states that his attention has been called by Dr. Wyllis Andrews to a notice of this anatomical feature by Walkow and Deletzin in a monograph on wandering kidney published in 1899. There seem also to be two references of importance showing earlier descriptions, one by Zuckerkandl in 1883 and one by Gerota in 1895.

10. **Puerperal Infection.**—Mann reviews the various operations suggested for this condition: 1. Curettage, with which he would be cautious. He is dubious as to its value in septic endometritis. The rule should be to do it only when clearly indicated; do it thoroughly, but not roughly or too forcible, and then do not repeat. If one fallopian tube is purulent, it is advisable to have it removed by abdominal incision. One of the most dangerous conditions which he thinks we can meet is the infection of a fibroid tumor or ovarian cyst. The presence of any kind of new growth in a puerperal woman should induce the greatest watchfulness and care. Septic infection in the presence of uterine fibroid, following labor, especially in abortion, should be taken as an indication for prompt hysterectomy. In cases of infected ovarian cyst, it should be removed, as probably also the uterus, though the latter should be governed by the conditions. Mann has not seen cases of ovarian abscess as described by Henrotin, but thinks his paper should be carefully studied by those who meet with such. In case of parametric abscess he is not entirely determined as to how to treat the case. He thinks it is better not to open the abdomen when there is evidence of acute post-operative suppuration. If necessary for diagnosis, open through the vagina; explore and drain, without opening up the healthy peritoneum if it can be avoided, or wait until the abscess gets large enough to show a fluctuating spot in the vagina and then open and drain. If an abscess in the broad ligament should be found on opening the abdomen, it is best to try and open it, with one hand in the abdomen as a guide, either into the vagina or at the groin, and not open it into the abdomen. Exploratory abdominal incision should be the rule, as Hirst says, only when it is the desire to determine if a pelvic mass, presumably suppurative, is situated within or without the peritoneal cavity, and whether it should be evacuated through the abdominal cavity or extraperitoneally. In septic peritonitis, when purulent accumulations, either encysted or free, can be determined, or are strongly suspected, the abdomen may be opened and washed out and drained. A free incision and full flushing with hot saline solution should follow. The diagnosis is often difficult. He mentions with approval Pryor's method of vaginal drainage early in septic infection, and as regards hysterectomy, remarks that it is the most important question of all. He thinks that he who operates often, operates too much in these cases. The removal of infected and thrombosed veins as suggested and carried out in puerperal pyemia is also noticed, but these cases are generally chronic and give time for study. He would open an ovarian abscess through the vagina rather than the abdomen. Ordinarily such abscesses and pus tubes rarely require operation within a month following labor.

11. **Suprarenal Extract.**—The authors have experimented on rabbits and found that suprarenal extract, which in the normal animal causes by subcutaneous injection no effect on the pupil and nearly no constricting effect on the blood vessels, has a distinct and lasting effect when the sympathetic nerve is cut. In other words, a substance which exerts no effect on a normal organ can exert a considerable effect of long duration if it is deprived of nervous control. This appears to them a principle of fundamental importance, which has an important bearing on therapeutics.

12. **Abdominal Incision.**—The different methods of closing abdominal incisions are noticed by Haggard, who recommends Davison's application of Haughey's method, by accurately closing each layer separately by reliable aseptic suture that can be easily drawn when it has accomplished its purpose. Davison has modified Haughey's method by putting a small reverse bowknot at the ends of the sutures, which acts like a shot on either end, and is easily untied when the suture is to be removed by simultaneous traction on both ends. The conclusions of his article are as follows:

1. The most reliable statistics prior to 1894 show that hernia occurs in from 6 to 29 per cent. of abdominal sections.
2. Suppurating abdominal wounds result in from 31 to 68 per cent. of hernia (according to the method of suturing).
3. The frequency of hernia is increased with the thickness of the parietal wall.
4. The longer the incision, the greater is the likelihood of hernia.
5. Drainage openings predispose to its production.
6. The site of the incision does not materially add to the occurrence, if suturing is uniform.
7. Abdominal supporters have absolutely nothing to do with the prophylaxis of this condition.
8. Subsequent pregnancy does not influence its occurrence.
9. The best preventive of postoperative hernia is the aseptic healing of the wound.
10. Through-and-through suture is satisfactory in thin subjects with short incisions, and is recommended when rapid closure is imperative.
11. The best method of suture is one which insures accurate coaptation of the fascia.
12. The method of closure in three layers by continuous silkwormgut in peritoneum fascia and subcutaneously seems to be freer from objections than any other. Its extended trial is desirable.
13. The patient should be confined to bed from 2½ to 3 weeks to insure thorough organization and consolidation.
14. After a wound is completely healed no other influence acts deleteriously upon the permanence and resistance of the cicatrix.
15. It is believed that less than 2 per cent. of abdominal incisions should become infected, and not over 3 per cent. of hernias should result.

13. **Infant Feeding.**—Mann advocates breast feeding wherever possible and deprecates the use of the commercial foods, of which we can not ensure the purity. The percentage method, while more difficult for the physician as requiring each case to be studied, is the best. He notices especially Freeman's method of milk modification, published in *American Medicine* of May 3, 1902, and abstracted in The Journal, xxxviii, ¶3, p. 1330. A child at birth has considerable iron stored up in its system, especially in the liver, which it draws on, as milk contains comparatively little iron, and if weaning is too long delayed the child may become anemic. From the seventh to the tenth month the ferments which digest farinaceous foods are present

in sufficient quantities to call for that class of foods. As soon as the teeth are developed enough to chew it, a dry crust of stale bread, at first once and later twice a day, is advised. This not only meets a want but helps to develop the jaws. The present custom of having all food chopped fine, he holds, is a mistake. Meat and its preparations should be allowed but little in infancy. Sufficient fats and carbohydrates are needed by the child to supply the demand for heat, energy, nervous and muscular work. Fats and carbohydrates decrease proteid metabolism and allow a normal growth and development of the child.

14. **Glaucoma.**—The later report of a case here given by Hansell shows that section of the sympathetics was negative in its results. The patient has had at least two attacks of glaucoma during the last eight months prior to writing of this paper, and since then, as stated in a note, has had a third attack. He thinks operation is justifiable in an exceedingly small number of cases. Those selected are simple, non-inflammatory and hemorrhagic glaucoma, and only after every other available remedy has been ineffectual, and the patient with a full understanding of the case asks for its performance. He thinks sympathectomy is inferior to enucleation in sightless, painful, glaucomatous eyes, for the danger in the former is greater and the result less sure.

15. **Hypodermoclysis in Pneumonia.**—Kahn recommends hypodermoclysis in pneumonia without previous phlebotomy and reports a case. He thinks it better to use veratrum viride, thus reducing the force of the heart and avoiding the anemic condition which exists after a large withdrawal of blood.

16. **Electrolysis in Eustachian Salpingitis.**—The following are the general conclusions of Matlack's article:

The 75 cases described represent applications of electrolysis extending into the thousands, which should be sufficient to allow a fairly accurate estimate of its value.

Excluding purely labyrinthine conditions, it has been of service in almost all other forms of deafness, and especially in cases of moderate degree, in which the most pronounced changes were in the tube.

The best results can not be obtained from its unaided use, so this should be supplemented by any other measures that have formerly been found of service. It is especially important to have free access to the tube, and to this end septum irregularities should always be corrected and hypertrophies of the turbinals cauterized. I use a routine way in all cases—solutions of iodin, menthol and camphor, conveyed to the parts by nebulizers—to improve the circulation in the nasopharyngeal mucous membrane. After electrolysis has restored the normal caliber of the tube, a further use of vapors to the middle ear after the method of Dench will be found of great value.

Patients who have been persuaded to continue in this line of treatment for a sufficient length of time are unanimous in their approval, and I am convinced that it marks a distinct advance in aural therapy.

Medical News, New York.

February 7.

18 Report of the Committee on Conference of the Medical Society of the State of New York.
19 *What Advice Should Be Given to a Woman Suffering from Fibroid Tumor of the Uterus? J. Riddle Goffe.
20 *Eye-strain. A. C. Bardes.
21 A Fatal Cases of Polyarthritis Complicated by Choreiform Symptoms and Vegetative Endocarditis. Augustus A. Eshner.
22 *Prostatic Calculi: With Report of a Case. John F. Erdmann.
23 *The Facts in a Case of Hematuria. Charles H. Chetwood.
24 *Trap-drummer's Neurosis: A Hitherto Undescribed Occupation Disease. Charles J. Aldrich.
25 *Experiments with a New Quinin Derivative. F. Pirkner.

19. **Fibroid Tumors.**—The proper treatment for fibroid tumors in a general way is removal by operation, whether they be large or small, in married women or single, only excepting women in very advanced life and those in whom the tumor is complicated by pregnancy. In the last case, Goffe holds that the course pursued must largely depend on the circumstances and conditions of the individual patient. As a rule most cases go to full term and normal delivery. With an expert, cesarean section is safer than myomectomy during gestation in the rare instances where such extreme measures are required.

20. **Eyestrain.**—Bardes considers eyestrain as one of the common causes of many inconvenient symptoms, headache, nervousness, etc., especially in large cities where the tall buildings and deficient sunlight are the rule. The only way is to give the eyes rest, but this is often inconvenient. Of course, the proper glasses should be fitted.

22. **Prostatic Calculi.**—After reporting a case Erdmann remarks in regard to these concretions, that they are usually of large size, rough, and generally found in extremely young or in middle and advanced life, and are seldom accompanied with marked urinary and bladder symptoms. They are due to calcareous degeneration of some previous inflammatory condition affecting the prostatic acini. They may give rise to absorption of surrounding tissue, cystic cavities or abscesses. They often lie dormant for a considerable time. Treatment is distinctly operative, and consists in making any of the accepted incisions for attacking the prostate. Care should be taken to see that none are left in the bladder to form a nucleus for further growth.

23. **Hematuria.**—Chetwood describes a case noteworthy from the fact of its four years' duration without general impairment of health, negative results of laboratory urinary analysis, the satisfactory cystoscopic picture, absence of morbid appearance presented in the gross showing of the kidney at the operation, the microscopic evidence of kidney lesion and the prompt cessation of hematuria following operation.

24. **Trap-Drummer's Neurosis.**—Aldrich's patient was a trap-drummer in an orchestra, who played a number of instruments with hand and foot. The work was hard and the result in this case was a neurosis consisting in a sense of great exhaustion in the muscles, especially the tibialis anticus and peronei of the right leg, with a sensation of pain and heat in the knee-cap, and a sense of constriction in the whole leg, with exhaustion experienced in the anterior muscular groups. After some hours of hard work the whole leg feels heavy, numb and lifeless. The patient was recommended to use the left leg, with apparently some relief.

25. **Saloquinin.**—Cases are reported by Pirkner of the use of salequinin in malaria and other conditions, a drug which he thinks can well take the place of quinin and is less irritating. In one case where there was a gastritis it seemed to exert a beneficial influence on the gastric innervation, vomiting being stopped when the use of the powder was resumed. The analgesic action of the drug was apparent in two cases, and several others reported showed the remarkable influence it has on diuresis.

Boston Medical and Surgical Journal.

February 5.

26 *On Paratyphoid Fever and Its Complications. Joseph H. Pratt.
27 Typhoid Fever at the Boston City Hospital in 1902. George G. Sears.
28 Typhoid Fever at the Massachusetts General Hospital. Herman F. Vickery.
29 *The Clinical Diagnosis of Typhoid Perforation. John C. Munro.
30 *Diet in Typhoid Fever. Frederick Shattuck.
31 *Typhoid Fever in Private Practice. J. T. G. Nichols.
32 *Upon the Presence of Typhoid Bacillus in the Urine and Sputum. Mark W. Richardson.

26. **Paratyphoid Fever.**—Pratt reports three cases of paratyphoid fever complicated with orchitis, cholelithiasis and phlebitis, and discusses the condition. In the first two he remarks the organism was the *Bacillus paratyphosus* of Buxton; in the latter a variety were present. He speaks of the importance of testing the blood with both groups of paratyphoids, which was strikingly shown in these cases. The condition is described, the symptoms, complications, etc., and the paper ends with a tabulation of recorded cases. He suggests the possibility that many cases of apparent recurrence of typhoid may be possibly paratyphoid cases for which the first infection left no immunity.

29. **Clinical Diagnosis of Typhoid Perforation.**—There were 15 operations in Munro's 26 cases, with one recovery. The diagnostic difficulties are noted. The symptoms early in the course of the fever varied a good deal, and Munro says that a combination of one or two symptoms suggesting peritoneal lesions might or might not exist early in the disease and might or might not persist. The gauge of each individual patient must be learned. The appearance of additional signs can be criticised for not forseeing such an accident, but there after the initial ones warrants early operation. A patient complaining of tenderness and distension suddenly developing spasm and vomiting, or chill with spasm, or any similar com-

bination, is probably developing a surgical lesion. Fulminating symptoms were noted in several of these cases, indicating wholesale infection of the abdomen or perforation. No one can be criticised for not foreseeing such an accident, but there were a number of cases where it was evident that a number of hours' warning had not been rightly interpreted. The need of sufficient nursing force at night is emphasized. Some cases with distension would be relieved by local applications or enemata; the pain would lessen after the first symptoms, and this false sign be given too great a weight. Permission for operation was sometimes obtained too late. As to the symptom of spasm he could not always estimate its significance. To get this sign rightly interpreted is the keynote of early attacks of perforation. In a large proportion of cases the leucocyte count has proven of very little value when most needed. The hemorrhagic cases were the most perplexing; the two conditions of perforation and hemorrhage may co-exist. In the one case of recovery the abdomen was opened six hours after perforation. In two cases that recovered without operation, he thinks the perforation healed spontaneously. The paper ends with brief descriptions of the cases, 26 altogether.

30. **The Diet in Typhoid.**—Shattuck gives the results of experience with some 563 cases, nearly equally divided between milk-fed and more generously-fed patients. He thinks the evidence is sufficient to warrant a further trial of the liberal dietary, as mortality and relapse seem to be less under it rather than greater, and hemorrhage and relapse no more frequent. In the 563 cases the mortality was 8.80 per cent.

31. **Typhoid Fever in Private Practice.**—Nichols insists on the importance of hygienic surroundings and good nursing, a sunny room with an open fireplace, without too much furniture or carpets, and well ventilated. He describes the method of ventilating by the window board, which can be moved as by a hinge from either end, thus giving the entering air the desired direction. If an air-tight stove has to be used it can be incased in sheet iron with suitable openings, cold air being brought from the window board by a tin tube to the space between the casing and the stove, the flow being controlled by a damper. The bed should be a single one, preferably of iron, with wire spring, a soft hair mattress covered with rubber cloth and a double layer of blankets over this. Sheets should be changed and the blankets aired daily, the mattress changed and aired often. If there is room there should be two beds, so that the patient may have a daily change with the least disturbance. If cold bathing is required, there is no difficulty in using cold sponging, spraying or sprinkling, and a fairly effective tub can be made on the bed with a few sandbags and a rubber sheet. Cleanliness and disinfection should be enjoined and the physician should see that they are thoroughly carried out. When these things have been attended to, drugs are of secondary importance and should only be used as conditions arise, the physician bearing in mind the Hippocratic maxim, "Do no harm."

32. **Typhoid Bacillus in the Urine and Sputum.**—Richardson sums up our present knowledge of the bacillus in the urine as follows:

1. Typhoid bacilli are present in the urines of about 21 per cent. of individuals afflicted with typhoid fever.
2. The bacilli, when present, are generally in pure culture, and their number is frequently enormous—many millions in each cubic centimeter of urine.
3. The invasion of the urine by the bacilli takes place in the later stages of the disease. Unless measures are taken to remove the organisms they persist frequently for weeks, occasionally for months, and rarely for years, and thus constitute (*a*) a danger to the patient himself (cystitis and possibly orchitis and epididymitis), and (*b*), what is much more important, a grave source of danger to the public health.
4. The necessity for the rigid disinfection and supervision of typhoid urines is apparent.
5. In urotropin we have a drug which will, in the vast majority of cases, remove the typhoid organisms from the urine, not only in the cases of simple bacilluria, but also in those in which a cystitis has resulted. Very rarely an obstinate cystitis may require the use of vesical irrigations. Very infrequently a case will be seen in which the use of urotropin is followed by hematuria. In such cases the drug should be omitted and irrigation of the bladder substituted.
6. This subject in its relation to the public health is of the utmost importance. In my opinion it should be a fixed rule, and one rigorously enforced, that no typhoid convalescent be discharged as well until his urine has been proved permanently free from bacilli. In large hospitals, with their well-equipped laboratories, such supervision can be carried out with ease. Cases in private practice should be the care of the local boards of health. In this way only can we prevent a considerable percentage of our typhoid convalescents from becoming unsuspected foci for the further distribution of the disease.

He has been able to isolate the organism in the sputum in a case of typhoid fever complicated with pneumonia, and other investigators have shown that it can be present in the sputum, especially if there is a co-existing bronchitis or pneumonia. The subject needs further study, but enough is known to show that in the sputum we have still another excretion which must be carefully disinfected.

33 *Tropical Diseases: Tropical Dysentery. (Continued.) Charles F. Kieffer.
34 *The Elevation of the Stomach in Gastroptosis by the Surgical Plication of the Gastrohepatic and Gastrophrenic Ligaments; an Original Operation. Henry D. Beyea.
35 *A Study of 55 Fatal Cases of Pertussis. Marion McH. Hull.
36 *What Is Irritable Bladder, and What Is the Best Method of Treating It? Louis Broter.
37 *The Significance of the Temperature in the Diagnosis of Extra-uterine Pregnancy During the Period of Collapse from Hemorrhage. Charles P. Noble.
38 An Improved Syringe for Intratracheal Medication. P. S. Donnellan.

33. **Tropical Diseases.**—Kieffer's third lecture treats of chronic dysentery, which he considers in the main to be of the amebic form. He gives illustrative cases and points out the evil possibilities if the disease is not checked. In most cases the chronic condition may be prevented by proper treatment, but unsuccessful attempts or only partial success is liable to cause serious consequences, sometimes even death from anemia, emaciation, etc. Another termination of these tropical cases is a sprue or psilosis, of which he will speak later. When bacillary dysentery becomes chronic, the clinical type is simply one of amelioration of symptoms of the acute stage. It is much more serious and more rapidly progressive than a parallel case of chronic amebic dysentery. The bowel movements number from five to fifteen daily. There is moderate griping, considerable tenderness over the colon; dyspeptic symptoms are pronounced, with flatulence, and a dry, glazed, eroded, beefy-looking tongue, which is constantly smarting and embarrassing eating. The development of sprue as a terminal state is not common. The pathologic conditions are similar to those of acute dysentery. There is ulceration, thickening in both forms, but the diphtheritic forms distinctly prevail with the bacillary type. The *Ameba coli* is constantly present in the amebic form, but in the bacillary form the Shiga bacillus appears in the chronic stage, especially when there is marked ulceration. As regards treatment, the general remedies are intestinal antiseptics such as bismuth, salol, either alone or in combination with bismuth and sulphur, which has been used by Stengel with success. Large doses of bismuth must be given. The local treatment is the main stay. They should not be used in acute recurrences of chronic cases; these should be combated as in the acute stage. It may be necessary to anesthetize the bowel with a 4 per cent. solution of cocain or a cocain and iodoform suppository. He would apply very gentle injections, of which the one of greatest value is silver nitrate, in the strength of 20 to 30 grains to the pint, using three to four pints under all precautions to avoid aggravating the bowel. When the injection is voided it must be in the recumbent position. No abdominal massage should be allowed. If tolerance is established he believes that either very hot or very cold injections are useful in establishing reaction. Creolin he ranks probably next to silver nitrate. Copper sulphate, zinc sulphate, chlorin water, hydrogen peroxid, etc., have been employed or recommended. An exclusive milk diet has been advocated, and if conscientiously carried out is of great value. It is our main stay in the treatment of sprue, but it is severe on the patient. We should endeavor to use nourishment which can be taken up in the small bowel and leave no bulky mass to be carried into the colon to decompose. Changes of climate are often of great value. We must bear in mind the possibility of complication of scorbutus, malaria, intestinal paralysis, etc. The prophylaxis consists in destroying the dysentery stools; never emptying them where they can get into water courses.

Great care should be exercised in the preparation of vegetables, especially when they are consumed raw. Constipation should receive great care, and the condition of the bowels generally. A flannel abdominal binder or "cholera belt" is of established value and should be worn, particularly at night. He would also advise patients to thoroughly wash their hands before each meal.

34. **Gastroptosis.**—Beyea's operation is described in detail. The principle is in placing three rows of interrupted silk sutures from above downward and from right to left through the gastrophrenic and gastrohepatic ligaments, a broad transverse fold or plication is formed in the shortening of these ligamentary supports, and the stomach is raised to normal position. The normal ligaments are shortened and the stomach is elevated to position without disturbing its physiologic mobility or functions. He reports a case and criticises the operations devised by Duret, Rovsing, Davis and others. He claims his own method is surgically and physiologically ideal.

> The completeness of the relief and, to my mind, the extraordinary restoration to excellent health of these 7 patients who had suffered for years; the simplicity of the operation (which restores the stomach to normal position by shortening of its natural ligaments without removal of tissue or the formation of abnormal adhesions), and the fact that it is practically free from danger (we would estimate the danger as being no greater than one-fourth of 1 per cent.), must strongly recommend this operation at least in every case of gastroptosis in which the suffering is great.

The patients thus far operated on, he admits, represent but one class, those with gastroptosis and without relaxation of the abdominal walls or diastasis of the recti muscles. Experience alone can teach what influence the operation will have when the relaxation of the abdominal walls is active in the production of gastroptosis. From the analogy of Alexander's operation he thinks it would appear that plication of the ligamentary supports of the stomach would ever and alone be sufficient, but if the contrary is found to be true, Webster's method of resection of the recti might be adopted.

35. **Pertussis.**—Hull gives his experience in an orphanage at Atlanta with which he is connected, and calls attention to the severity of the disease and warns against popular and medical opinion in regard to the evil. We should take greater care to prevent and eradicate this very dangerous disorder.

36. **Irritable Bladder.**—According to Broter's experience, every case of irritable bladder is due to some pathologic lesion on the inner surface of the wall, usually at or near the neck. This may be the result of pressure from displaced abdominal organs or tumor or bacterial infection, trauma, use of the catheter, adjacent diseases, gonorrhea, etc., and pathologically very much resemble chronic cystitis. The first symptom is the desire for frequent urination, with insufficient quantity, heaviness or painful feeling in the hypogastrium. The difference from cystitis is that in one we have a general inflammation of the vesical mucosa, while in the other we have only a localized inflammatory condition. He mentions in regard to prophylaxis, care as to the use of instruments introduced into the organ, thorough treatment of every case of urethritis and great care in the administration of toxic drugs which may cause irritation. All irritating substances such as alcohol, beer, acids and spices should be avoided. Only a mild diet of soups, milk, etc., should be used. He employs a warm saturated solution of boric acid followed by a 1 per cent. solution of silver nitrate, allowing this to remain in the bladder for three or four minutes, drawing it off, and introducing about three ounces of a 2 per cent. to a 10 per cent. solution of ichthyol in water, and allowing this to remain in the bladder for at least half an hour. A silver injection may cause considerable pain, but this can be remedied by anesthetizing the bladder previously with a 1 per cent. solution of cocain. The treatment should be repeated every other day for three or four weeks. Permanent cure usually results.

37. **Extra-Uterine Pregnancy.**—Noble reports a case in which the patient was seen during the period of collapse from hemorrhage and there was a febrile temperature. It showed that the rise of temperature the second hour after onset of symptoms of ectopic pregnancy does not exclude the diagnosis of collapse from hemorrhage.

44 The Treatment of Buboes that Threaten to Suppurate. Elbert S. Sherman, J. A. Nydegger, Chas. D. Luckett, Joseph N. Weller and Wm. A. Groat.

39. **Astigmatism.**—Bull reports a case of inverse astigmia of 1.75 D., due in large part to the corneal curvature being greatest in the horizontal meridian, in which he relieved the condition by tenotomy of the left external rectus, being careful not to cut the capsule much below the upper and the lower borders of the tendon. He remarks that the operation has been very satisfactory. He thinks, however, that such measures for the correction of astigmatism should be undertaken in only very exceptional cases. The importance of the case depends not on the cure, but on the light which it throws on other questions. It shows that the tension of the external muscles may have a considerable bearing on intraocular tension and he suggests that the cause of the inverse astigmia so common in glaucoma may possibly be found in the position and relative tension of these ocular muscles, and proposes to go into this subject and examine carefully to determine whether glaucoma can be relieved by tenotomy.

40. **Immigration and Tuberculosis.**—Shively points out the undesirable character of many immigrants as regards disease, especially those that smuggle themselves through from Canada to this country. He remarks that the Jews who are said to be specially immune to tuberculosis are not showing their immunity among the immigrants in New York. The immigrant Jew generally follows an unhealthy sedentary occupation and this also favors the spread of consumption. Other nationalities, of course, are undesirable in the same way. He thinks the privilege of American citizenship is too cheap and thinks we should quarantine against tuberculosis.

41. **Tuberculous Laryngitis.**—Sharp describes two forms of tuberculous laryngitis: 1. Where ulceration is confined to the true cords, ventricular bands and interarytenoid commissure, without surrounding infiltration. These cases, with little digestive disturbance and the toleration of creasote, have a fair chance of recovery. 2. Cases of ulceration of the arytenoids, aryepiglottic fold, true cords, and ventricular bands with infiltration, or infiltration without ulceration, these are hopeless. He mentions the difficulty in diagnosing tuberculous from syphilitic ulceration. Another condition which may give trouble in the diagnosis is characterized by cough, difficulty in breathing, husky voice, thickening of the arytenoid commissure, presenting a stellate appearance frequently mistaken for ulceration. This is common in washerwomen and others who expose themselves to quick changes in temperature, but is amenable to treatment and outdoor life for a cure. He does not believe there is such a thing as primary tuberculosis of the larynx in any case. It is always a secondary process.

42. **Common Colds.**—Zahorsky thinks colds are contagious and that we should fortify the system against these, attend to general nutrition, prescribe healthy outdoor exercise and outdoor life and good ventilation of sleeping rooms. He doubts much the influence of remedies on colds. Until we know just what the infecting agent is, we can very rarely abort a cold. We can only treat the patient symptomatically and make him more comfortable.

43. **Appendicitis.**—Six cases are reported by Lilienthal, one associated with typhoid, another with hemorrhagic symptoms, another complicated with septic nephritis and a fourth where the appendix lay between the layers of the mesocolon and a high degree of aseptic absorption has taken place. Another with syphilitic complications, etc.

45 *Medical Education. Horace J. Whitacre.
46 Surgery of the Prostate, Pancreas, Diaphragm and Spleen. (Continued.) B. Merrill Ricketts.

45. **Medical Education.**—Whitacre discusses the various points in medical education which have been brought out as to the private school, university school, semi-university school; preliminary educational requirements, organization, didactic lectures, recitations, laboratory teaching, clinical teaching, curriculum, the elective system, etc. He thinks the true university basis is correct and that the subjects of anatomy, physiology, chemistry, pathology, bacteriology, etc., should be taught in the university by salaried teachers. He questioned a number of physicians as regards their opinion of the courses followed by them, and their choice as to the election of a specialty before or after graduation. In 81 per cent. the course was thought insufficient, and 17 per cent. felt that much useless detail might be eliminated. The majority of those who selected a specialty before graduation found after graduation that they had made a mistake. He gives an estimate of the financial expense of running a medical college, including salaries, which shows that it can not depend alone on the fees of its students for its support.

49 *The Preparation of the Patient for an Operation and the Relative Value of the Blood Examination. A. E. Benjamin.
50 Report of a Case of Operation for Obstruction of the Bowel in a Very Young Infant. F. J. Campbell.

48. **Colles' Fracture.**—Pond mentions the usual method of reduction, but we occasionally meet cases which can not be thus managed. A man about 32 years of age fell from the second story of a building and had a fracture of the right radius. Attempts to reduce it in the usual way with or without anesthesia, failed, and it occurred to him that if the fracture was caused by extreme extension, it might possibly be reduced by extreme flexion, and consequently the elbow was flexed and rested securely on the table, the hand was grasped and forcible flexion made. At the same time pressure was exerted on the prominence. Reduction was easily accomplished, and can be explained thus: The metacarpal bones were used as a lever; these resting on the semilunar converted it into a fulcrum, and lifted the head of the impacted radius until reduction was possible. He has never before seen this method described, but has always employed it since that time, with uniformly good results. He has used with very gratifying results the method of dressing described by Dr. Moore of Rochester, N. Y., using a roller bandage about one-half inch in diameter as a splint on the palmar surface of the fracture and held in place by a strap of strong adhesive plaster, the whole supported by a sling. In children, however, it is his practice to make a splint composed of several thicknesses of canton flannel immersed in a paste plaster of paris, thus making a special splint for each individual fracture. These harden and become firm enough to prevent luxation of the fragment, and also hard enough to protect the arm from injuries by blows or falls.

49. **Blood Examination Before Operation.**—Benjamin offers the following conclusions of his paper:

1. The necessary preparation of a patient for an operation is too often neglected. 2. The time for the preparation is frequently too short. 3. The general state of the patient before operating is as important as the pathology of the local disease present. 4. Many post-operative complications arise that could be avoided by proper preliminary treatment. 5. The leucocyte count and hemoglobin estimate should be employed as an aid to diagnosis and as a basis of treatment in surgical cases before operation. 6. By the blood examination we may be able to confirm our diagnosis made from clinical symptoms, or we are able to make a diagnosis of concealed pus when not determined otherwise. 7. We may save our patient's life by delaying the operation until the per cent. of hemoglobin reaches a safe standard, or the white count reaches nearer the normal line. 8. We may be justified in operating at once in a case where the white count is rapidly rising or the hemoglobin is gradually falling.

57 Pott's Disease. Emma S. Merritt.

53. **Care of the Insane.**—Gardner discusses the state care of the insane and condemns especially the political influence and pull in the administration of state institutions.

54. **Tuberculosis.**—Pottenger protests against the proposed legislation excluding consumptives from California, showing that it will be useless and inhuman. The resolutions adopted by the Los Angeles Medical Society against such measures are appended.

55. **Oophorectomy.**—From his experience Lindley finds little benefit from oöphorectomy in nervous disorders, etc. The three cases reported all relapsed, though there was temporary benefit. He gives the opinions of others and sums up by saying in selected cases of insanity and epilepsy where there is real disease of the ovaries, producing an artificial menopause is advisable and justifiable, and that with any woman who has diseased ovaries the fear of producing nervous and mental diseases should not in any way interfere with the decision to promptly operate, but the preferable operation is to remove the uterus and leave the ovaries.

64 *Acute Intestinal Obstruction Following Operation for Acute Appendicitis. John B. Deaver.
65 *The Clinical Significance of Ascites. Arthur R. Edwards.
66 *Insanity Following Surgical Operations. Richard Dewey.
67 *Arthritis Deformans in Children. I. A. Abt.
68 The Recognition and Care of Catarrhal Diseases of the Accessory Sinuses. Henry B. Hitz.

64. **Intestinal Obstruction After Appendicitis Operation.**—Deaver finds that delay in operating in acute appendicitis may cause intestinal obstruction and that immediate operation offers the only hope for life in many cases. He notices the symptoms and methods of treatment and reports a number of cases.

65. **Ascites.**—Edwards recapitulates his paper in the following:

1. In general the sum total of physical signs of ascites is unequivocal. 2. The individual signs are not infrequently ambiguous. Tympany, e. g., may be elicited by heavy percussion from contiguous intestines or may be present over the entire abdomen on account of physical laws as yet not finally determined. 3. Ascites may be free, encapsulated, or both conditions may be coincident. 4. Ascites may be mechanical, vascular, due to stasis. 5. It may be due to increased permeability of the blood vessels, i. e., hydremia or cachexia. 6. A third cause is inflammation. 7. A high specific gravity and a high percentage of albumin usually indicates exudation, although there is no close nor invariable correspondence between them, and no absolute physical line can be drawn between the fluid of exudation and the fluid of transudation. 8. The microscopic examination may determine the character of the fluid and again the variety of the inflammation. 9. Operation may be the only method of final diagnosis. 10. Hyaloserositis must be considered. 11. Ascites may cover small ovarian or other pelvic growths.

66. **Insanity Following Surgical Operations.**—Dewey's paper, as far as it gives results, does not indicate a very great danger of insanity after surgical operation. He calls attention to the neuropathic or psychopathic conditions, hemorrhagic diathesis, etc., as matters to be guarded against, as well as the mental condition of the patient. Toxemia, malnutrition, previous attacks of neurasthenia or insanity, alcohol or drug habits and anesthesia, all have a bearing on the possibility of insanity after operation.

67. **Arthritis Deformans.**—Abt discusses the condition in children and reports a case.

74 *Chronic Sphenoiditis in Its Relation to Disease of the Middle Ear. Francis P. Emerson.
75 Tonsillitis Localized in a Supernumerary Tonsil. Fayette C. Ewing.

70. **Eustachian Electrolysis.**—Pierce concludes that in otosclerotic disease electrolysis is useless. In the great majority of catarrhal cases it has no advantages over other methods of treatment. In a limited number where there is probably a soft exudate near the isthmus, it may be regarded as of some value.

74. **Chronic Sphenoiditis.**—Emerson reports the results of an analysis of 268 cases where caries of the sphenoid was found 25 times. Twenty-one cases were associated with chronic catarrhal and 4 with chronic suppurative ears. Seven presented catarrh on one side and chronic suppuration on the other. In 2 there was only a record of cerumen. Various nervous symptoms, headache, etc., were noted, and in a large proportion ethmoid tumors occurred. While but little difficulty was experienced in probing the sinus, still there was a considerable number with narrow ostia, where a flexible silver probe one-half the size and with the head fused on the end, added greatly to the detection of small rough areas and in some was the only practical instrument. It seemed to have a special beneficial effect in these old chronic cases. There was a practical gain in hearing in many of the cases that was unexpected.

77. **Atropin Idiosyncrasy.**—Phillips reports a case where homatropin and atropin produced myosis instead of the usual effects. The same homatropin used on another patient produced a mydriatic effect.

80. **Uveitis.**—An accident first showed to Morton eleven years ago the beneficial action of large doses of salicylates in plastic iritis. Since that time he has used these drugs in practically all cases of inflammation of the uveal tract with very satisfactory results. The usual dosage of from 10 to 20 grains is attended with no noticeable benefit, but the administration of 30 to 60 grains of the salicylate of soda and repeated will often prove efficient in hastening resolution and acts most favorably as an analgesic. In severe cases he gives 40 grains every two or three hours until relief is obtained or continuance is inadvisable. If any unfavorable results appear it may be discontinued for an interval and again repeated. He finds it best administered in cold water on an empty stomach.

83. **Amblyopia.**—After noticing some cases in the literature, Friedenwald reports the case of a man 78 years of age who had cataract with marked impairment of vision in the right eye, and in the left chronic glaucoma, with the usual visual disturbance. An operation was done for removing the cataract and recovery was rapid and smooth. It was a disappointment, however, to find that, notwithstanding clear media, the patient still saw very badly. Some months later when again seen the vision of the left eye had become further reduced, but the right eye had markedly improved. After operation the vision was so poor that glasses were not ordered, the impression being that the sight was impaired beyond recovery. Nine months passed before decided improvement was noticed and glasses were then given and the sight improved gradually so that in two months more it had reached 10.40 and in 2½ years equaled 16.40. He thinks no other hypothesis than the production of amblyopia from non-use will satisfactorily explain the later gradual recovery of vision.

86. **Magnet Operations.**—Fisher describes the method of the use of different magnets, more especially the Haab giant magnet. He favors removal through the anterior chamber on account of the risk of the episcleral opening. If the metal fragment is very large, the chance of injury to the lens is not of much importance, for a large piece usually destroys the eye. With small ones it is often possible to draw it around the lens through the zonula into the anterior chamber without wounding the lens.

88 *Contusion of the Abdomen. Geo. S. Rennie.
89 Four Cases of Herniæ. Thomas J. F. Murphy.
90 *Tonsillar Hypertrophy: Its Operative Treatment, and the Comparative Value of the Different Methods. Perry G. Goldsmith.
91 Some Notes on Examinations for Life Assurance. John L. Davison.

88. **Contusions of the Abdomen.**—Three cases of this condition are first reported by Rennie, one of which terminated fatally. He then reviews the symptoms and the indications for operation. He thinks the condition is often overlooked and the symptoms are frequently deceptive and the seriousness of the case not appreciated until it is too late. An exploratory operation is not only safe but it is the only means of arriving at a correct diagnosis where there is no possible suspicion of injury to the internal viscera. Therefore, he advises early operation in all cases.

90. **Tonsillar Hypertrophy.**—The indications for removal of the tonsils in Goldsmith's review are: 1. Deafness associated with overgrowth, enlarged tonsils in debilitated children or adults, frequent attacks of tonsillar or peritonsillar inflammation, tonsils filled with caseous material, causing impaired nutrition, foul breath, as well as keeping up a chronic pharyngitis, enlargement sufficient to impede speech, respiration or deglutition and small submerged tonsils, whose structure is often one suppurating mass and associated with subtonsillar disease. The various methods are noticed and he advises against the use of the guillotine in people above 17 years of age and also in submerged tonsils, except when projecting during an acute attack of inflammation. It is best to remove the whole tonsil, and this is not always easy with this instrument. The cold snare is thorough and safe. It should not be too fine. The tonsil should be crushed rather than cut on account of possible hemorrhage. The Dundas Grant tonsil punch is especially useful in the small hard tonsils of adults and the long flat tonsils where it is almost impossible to get sufficient of their substance into the guillotine. He has had no experience with the hot snare and sees no advantage with it on account of hemorrhage, which is a serious matter. Even in the milder dressings he advises that great care be taken for some time after operation as hemorrhage may be delayed for one or two weeks. Avoidance of all exertion, and any tendency to clear or separate the crust should be guarded against and the eschar which forms should be allowed to come away itself. In cases of hemophilia operation should be refused. He reports cases illustrating his remarks.

99 *Spinal Cord Conditions in Severe Anemias. Archibald Church.

92.—This article appeared elsewhere. See THE JOURNAL, xxxix, title 95, p. 1137.

94. **Dacrocystitis.**—Clark remarks on the paucity of the literature of this subject and suggests that lack of a plan of treatment may be the cause. The method he has employed has been the use of chlorid of zinc. He reports two cases. In the first, other measures failing, he injected into the sac three drops of a 20 per cent. solution. There was violent reaction, but the treatment restored absolutely every function of the drainage system permanently. He would hesitate to advise so strong a solution as this, feeling that one would be safer in not going over 10 per cent. Froelich, who recommended the method, used a 5 per cent. strength. His results make him enthusiastic as to this method of handling dacryocystitis.

96.—This article appeared elsewhere. See THE JOURNAL, xxxix, ¶44, p. 1619.

97. **Congenital Phimosis.**—Hunt protests against the too frequent practice of operation for this condition, holding that it cures itself in a great majority of cases. He is convinced that the so-called reflex influences attributed to it have been greatly exaggerated.

100 Creosote. Cornelius Skinner.
101 *A Preliminary Report on Tetra-ethyl-Ammonium-Hydrate and Solution of Chlorid of Platinum. Joseph W. Irwin.

101. **Tetra-Ethyl-Ammonium-Hydrate.**—Irwin's attention was called to this drug by notice of it in the journals and having several cases that needed a uric acid solvent, he prescribed it. These included several cases of chronic rheumatism and three of arthritis deformans, in which the results were most satisfactory. He gave it in the usual recognized dose, 5 to 15 minims of a 10 per cent. solution in mixture three times a day. He also notes a case of what he considers gastric cancer treated with chlorid of platinum, one drop of a 1 per cent. solution, increased gradually up to 5 drops, with great benefit. In a second case which he has also treated in the same way it has relieved pains and the cachexia is disappearing.

3. **Morbid Impossibility to Remain Seated.**—Haskowic first described this condition last November and applied the term "Akathisia" to it. The subject can seat himself and remain seated a few minutes, but then the contortions begin, and unless he gets up he suffers actual torture. When he rises to his feet the symptoms vanish. Haskowic was inclined to seek for some organic foundation, but Raymond has recently observed a case with the same syndrome, and the circumstances and general aspect of the case classed it at once as a professional phobia.

4. **Biologic Life of a Xiphopagus.**—The Chinese united twins, or xiphopagus, now being exhibited in Europe, were subjected to a physical examination by all the known laboratory tests. The results show a most interesting harmony between the individual life of each twin and the fundamental biologic life in common.

11. **Organic Lesions in Tabes.**—This article is based on the clinical and postmortem examination of 11 subjects, observed in Déjérine's service. The results demonstrate that the essential lesion in tabes is a dystrophy affecting the entire peripheral sensory neuron, although most pronounced in the central prolongation of the nerve cell. It generally affects also certain portions of the motor protoneuron and of the sympathetic system. The histologic alterations are characterized by modifications of the nerve fibers comparable in certain respects to those noted in the course of toxic neuritis. They differ completely from those of Wallerian degeneration. The cell body of the sensory protoneuron generally seems intact, but at times it presents evidence of atrophy. Even in the absence of actual definite lesions, it is legitimate to suppose that its trophic function is to some extent compromised under the circumstances.

17. **New Tendencies in Therapeutics.**—In this address at the Egyptian Congress Bouchard expatiated on the absurdity of dosing with 6 gm. of sodium salicylate, for instance, to cure a single joint lesion. If the diseased part weighs 50 to 100 gm. in a man of 120 pounds, for instance, then only 5 to 10 mg. finds its way to this diseased part and cures it, while the remaining 599 cg. is not only useless and superfluous but directly injurious. He has been proclaiming this principle for some months and now brings details of cases showing that the proportionate fraction of the general dose, injected locally, will heal a local rheumatic arthritis. He has also been successful in the same way with pleurisies and even in rheumatic pericarditis. In the latter affection a local injection of 10 cg. reduced the temperature from 39 to 37.6 C. and the friction sounds vanished after a second injection in one case. Benedikt has reported the cure of severe peri-, endo- and myocarditis in the course of acute articular rheumatism, by local injections of phenic acid, but Bouchard has not been so successful in endocarditis. He has cured by local salicylic medication painful muscular contracture of the adductors of the thigh, injecting it into the insertions of the tendons. Also sciatica and the neuritis of zona. In inflammation of a serosa he does not inject the medicine into a closed cavity but into the diseased tissues or the vicinity. He has also attempted this method in the treatment of the fulminating pains of tabes, but without results, although successful with local medication in syphilis as an adjuvant to general treatment. He has witnessed the subsidence of gummata and neuritis after local injections of 1 to 6 c.c. of potassium iodid or .2 mg. of bi-iodid of mercury. He reiterates that wise therapeutics tends more and more to supplement or supplant general with local measures either for their antiseptic action or for their stimulating influence on the antitoxic reaction.

20. **Pathogeny of Tabes.**—Nageotte believes that he has established that tabes is the result of a transverse interstitial radicular neuritis, an inflammatory lesion variable in its virulence and capricious in its localization. It is preceded by a syphilitic meningitis, and clinicians should recognize and treat this before the development of the process affecting the noble elements. Thanks to Widal, we have now a certain means of detecting this meningitis while it is still uncomplicated, before any symptoms have developed. No one should hesitate to perform lumbar puncture in syphilitics at the slightest suspicious symptoms, he remarks, perhaps even as a routine measure at a certain stage of the syphilitic infection without waiting for symptoms to develop.

21. **Gingivo-Dental Treatment of Alopecia.**—The trophoneurotic theory of alopecia suggests treatment of the jaws and teeth as important factors in its cure. Trémolières reviews recent experience in this line. In all but 2 out of 21 cases attention to the mouth was followed by the regrowth of the hair. The failures may be possibly attributed to the development at the time of the wisdom teeth.

22. **Exaggeration of Reflexes Sign of Carcinosis.**—De Buck published last year an account of a case of carcinoma of the breast in which the degeneration of the spinal cord was as marked as in case of compression from a metastasis. This led him to study the nervous system in case of carcinosis and he found that in almost every case of carcinoma or sarcoma, wherever its location, the tendon reflexes were more or less exaggerated. The cutaneous reflexes were variable, exaggerated in some. Babinski's sign was never noted. The exaggeration of the tendon reflexes was observed before the cancerous dyscrasia was very pronounced, the tumor very large, or the lymphatics involved. It is not found with the same intensity, regularity nor constancy in the incipient stages of any other toxemia, according to his experience.

28. **The Bryocytic Diseases.**—Bosc proposes the name bryocytobe for the living parasite which induces proliferation of cells, or the more euphonious term, bryocyte. The organism reacts differently to various parasitic invasions, the defense being along different lines. In acute microbian diseases, for example, the cellular proliferation affects the leucocytes more particularly; in other diseases the fixed cells are affected. From the study of the various morbid groups and especially of the blastomycetic reactions, he has become convinced of the existence of a type of disease hitherto ignored. This new type has structural and histogenetic characteristics in common with true cancerous neoplasia, while at the same time it is infectious and virulent. It includes variola in which the pustules are characterized by a proliferation of the epithelium with invading tendencies, degenerative and irregularly progressing. The pustule is evidently the means of defense employed by the organism. The polynucleosis observed is directed principally against the remains of the degenerated cells of the pustule. The peculiarities of this group of diseases are best studied in the variola of sheep, sheep-pox, which seems to be the intermediate type between variola, vaccine and aphthous fever on one hand and syphilis and cancer on the other. He describes in detail the various points which have led him to this conception of the cancerous tumor as an indefinitely progressive inoculation pustule. The chancre in syphilis is also of this type, accompanied by evidences of participation of the lymphatics in the defense, as occurs also in sheep-pox. The long duration of the eruption and the recurrence of symptoms from time to time show that it partakes of the character of indefinite progression, which is a marked attribute of cancer. In syphilis, as in the other diseases of this group, mononucleosis at first chiefly prevails. The polynucleosis occurring later is evidently due to secondary infection or to the disintegration of the lesions. The essential lesion is an epithelial proliferation; the pustulous lesions in the organs are similarly epithelial, while the connective tissue involvement in the lesion is precisely like that observed in sheep-pox. All these diseases are links in the

chain of lesions which are defensive processes on the part of the organism seeking to immure the parasite in its nest. The various phases of the inflammatory process show it to be the most exalted and specialized type of defensive inflammatory reaction, with cancer as its ultimatum. He has succeeded in producing an anti-sheep-pox serum which has proved powerful and effectual, and these results encourage the hope that the same method of treatment may yet prove successful for all the diseases in this group. In regard to the causal germ, he is inclined to accept the cell inclusions observed in vaccine, variola and cancer and suggests the term bryocytes as mentioned above, from the Greek word to make proliferate. This group should, therefore, be classed as the bryocytic diseases.

30. **Homogenization of Clot in Search for Bacilli.**—The method described is like Jousset's, mentioned below. Five c.c. of blood are mixed with 5 c.c. of distilled water and 5 drops of caustic soda until the coagulum is dissolved. Twenty c.c. of water are then added and the whole boiled for ten minutes. It is then poured into two tubes and centrifugalized, when tubercle bacilli are easily distinguished in the sediment under the microscope.

35. **Anaerobic Microbes in Urinary Infection.**—Albarran remarks that bacteriologic inspection of urinary infection is not complete without search for anaërobic bacilli. He found 9 different varieties in a number of patients examined. In one case of pyonephrosis the anaërobics were alone; in 3 associated with aërobics, and in 2 the latter were alone. In 3 cases of tuberculous renal infection he found anaërobics in one. In cases of infection of the bladder and cystitis he found sometimes aërobics exclusively and sometimes anaërobics or both combined. A very virulent anaërobic was found in one out of 4 cases of suppurative prostatitis. In 25 cases of periurethral infection from infiltration of urine or urinary abscess, anaërobics were absent in only 2; in 16 they were associated with aërobics, and in 7 the anaërobics were alone. The importance of the anaërobics in the generation of secondary infections by way of the blood is demonstrated by one case observed in which there was infiltration of urine and a secondary phlebitis with abscess at the knee. The colon bacillus and an anaërobic were found associated in the perineal focus, but the latter was found alone in the metastatic abscess.

41 *Du myelome multiple des os (of the bones) avec albumosurie. Etude des tumeurs primitives multiples du squelette. P. Vignard and L. Gallavardin.

37. **Intermittent Hydronephrosis.**—Bazy describes 2 cases cured by ureter-pyelo-neostomy. In these, and in 2 somewhat similar cases the obstruction to the flow of urine proved to be one or more folds in the ureter as it entered the pelvis, the folds held in place by external adhesions, or else there was actual constriction of the ureter at this point. Removal of the adhesions or excision of the stricture resulted in a complete cure. In 2 of these cases there were no evidences of infection. In order to study the possible origin of the adhesions in these aseptic cases he examined the ureters and kidneys in a large number of newborn infants which might include some who would have had hydronephrosis if they had lived to grow up. More than 100 were examined and injected, and he gives cuts of 63 such ureters still attached to the pelvis. Only a few were regular. The others exhibited numerous strictures, folds and other irregularities. Only 15 presented a normally regular aspect their entire length. All the others exhibited folds, constriction or torsion, and generally multiple. Some of the ureters and some of the pelves were large; others very small. Some must have allowed the absolutely free passage of urine; others would have favored retention on the slightest provocation. Reviewing the data observed and his clinical experience Bazy thinks that they explain why surgical intervention limited to resecting a portion of the renal parenchyma, or something of the kind, in the hope to abolish the cavities or culs-de-sac, is usually useless and is based on an incomplete knowledge of the pathologic physiology of hydronephrosis. It is due, especially the intermittent form, to some congenital predisposition of the pelvis and accessorily of the ureter. The maximum of these conditions is the combination of a large pelvis, horizontal, shaped like an elbow or bagpipe, with strictures, folds or torsion of the upper end of the ureter. Hydronephrosis may be the consequence of a movable kidney, but generally the ptosis and movability are consecutive to the hydronephrosis. The torsion, folds or constriction may be rendered permanent by adhesions or by a sclerosis of the walls connected with some irritative process, from attenuated infection or aseptic irritation.

41. **Multiple Myeloma of the Bones.**—Reviewing a case personally observed and four collected in the literature, these writers claim a special place for primary multiple tumors of the bones. They develop at several points in the bony frame apparently simultaneously, although it is not always possible to distinguish between the primary tumor and the metastatic nodules. The tumors develop principally in the bones with red marrow, sternum, ribs, vertebræ and skull. They are never accompanied by visceral generalization, and they remain restricted to the skeleton. Some of this group of tumors exhibit the aspect of lymphadenoma, others of endothelioma, while still others have the special structure of myeloma, as in the case personally observed. The latter class is further distinguished by the large numbers of the tumors, their possible clinical latency, the rapid cachexia, fever and terminal coma, and the finding of Bence Jones' albumose in the urine. His patient was a man of 56, with no alcoholic, malarial nor syphilitic antecedents. The affection commenced with a sudden pain in the ribs, coughing and expectoration and entailed rapid cachexia and death in less than six weeks. All the ribs and the sternum were affected with the tumors, some as large as a walnut.

46 *Inoscopy or Fibrinoscopy. A. Jousset.—Nouvelle méthode pour isoler le bacille de Koch des humeurs de l'organisme.

42. **Site of Gallstones.**—Ehret thinks that important information may be derived in regard to the location of gallstones by observing the character of the febrile attacks, the icterus, the pain and the composition of the blood, in cases with little, if any, icterus in the intervals and with the color of the stools showing the influence of bile. The fever, for instance, is abrupt, rises high and disappears in a few hours when the stone is in the lower biliary passages. On the other hand, when the stone is in the gall bladder the fever is apt to be less intense, or it may be prolonged for several days. Numerous attacks of icterus, rapidly succeeding each other, indicate stones in the bile duct. This is indicated further by the character of the pains, which are not violent. The patients may feel no pain or merely a dull ache in the region of the liver. Violent pains accompanying the attacks point to the gall bladder. When the number of leucocytes is increased and remains high even during the intervals, the purulent focus indicated by this hyperleucocytosis must be in the gall bladder. The evidence of bile in the color of the stools is incompatible with the assumption of an ascending suppurative angiocholitis originating in the bile duct. On the contrary, if the number of leucocytes is normal in the intervals, while it increases notably during attacks, the fact is strongly in favor of a gallstone impacted in the bile duct.

43. **Cystoscopy of the Nasopharynx.**—Valentin calls the little instrument he has invented for the purpose of examining the internal orifices of the eustachian tubes, the salpingoscope. It is inserted through the lower nasal meatus and the views obtained far surpass those attainable by any other method. He

gives cuts showing the behavior of the orifice of the tube, which varies in pathologic conditions. The findings may prove an additional means of diagnosing certain affections of this region.

44. **Hemolysis in Cerebrospinal Fluid.**—Bard has examined the hemolytic power of the cerebrospinal fluid, supplementary to cytologic findings, and proclaims that important information may be derived from it. Very little of the fluid is required; the procedure is rapid and simple and the results can be determined with the naked eye. Five to 10 drops of the cerebrospinal fluid are placed in each one of a row of centrifugalizer tubes and distilled water added to each in turn. The first tube has no water; to the second 2 drops of water are added; to the third 4 drops; to the fourth 6 drops, and so on. In normal conditions hemolysis is first observed with 12 drops of water to 10 drops of cerebrospinal fluid. If it occurs with less water or is very marked with 12 drops, the fluid is pathologic. The hemolytic power is high in the commencement of an affection, but, as the defensive powers of the organism come into play, it falls and is frequently below normal as recovery approaches. The findings parallel those of cytology in certain affections but differ widely from them in others. The method has proved especially useful for the differentiation of obscure causes of hemiplegia, and also to separate purely functional troubles of the central nervous system from those which depend on an infectious or toxic origin.

46. **Inoscopy.**—Jousset has coined this term from the Greek word for fibrin to describe his method of distinguishing the Koch bacillus by artificial digestion of the fibrinous matters in the sputum, blood or effusion to be examined. He has found the most effective fluid for the purpose to be a mixture of 1 to 2 gm. of pepsin in glycerin and hydrochloric acid, each 10 c.c., and 3 gm. of sodium fluorid, with 1000 gm. water. The results were positive in 23 cases of pleurisy examined, working on 10 to 500 gm. of serous fluid. In 12 cases of ascites the bacillus was found in 8, and in 3 of these the clinical signs all pointed to a liver affection, but the autopsy confirmed the tuberculous nature of the disease. Differentiation was also possible by this means in 2 cases supposed to be typhoid fever, and in a number of cases of unsuspected tuberculous affections. The method also reveals gonococci and other pathogenic germs, but is especially useful in respect to the tubercle bacillus.

71 Apparat zur Cervix- und Uterus-Behandlung mit flüssigen (fluid) Medikamenten. Ibid.

61. **Operative Treatment of Puerperal Pyemia.**—Sippel states that he advocated operative treatment long before Trendelenburg, but has had no opportunity to apply it. Two of his four patients recovered spontaneously, and the others for external reasons could not be operated on, and both died. The intervention he proposes is to remove the uterus in case of purulent phlebitis with the clinical picture of acute pyemia, and at the same time resect the veins involved. He does not approve of the extraperitoneal method followed by Trendelenburg in the case he reported of successful ligation of the hypogastric and uterine veins. He remarks, in conclusion, that operative intervention should be reserved for a last resort, as many cases of pyemia terminate in spontaneous recovery.

63. **Ventrofixation of Uterus.**—Kreutzmann gives several reasons why ventrofixation should be discarded, advocating in mobile retroflexio vaginofixation or the Alexander-Adams, and in other cases, mobilization followed by the shortening of the round ligaments.

73 (No. 11.) *Ueber direkte Fettanreicherung (fattening) atrophische oder drüsenkranker Kinder (emaciated or scrofulous children). L. Furst.
74 (No. 12.) Fall von Purpura hemorrhagica nach Masern (after measles). L. Falk.

72. **Importance of Lymph Glands in Tuberculosis and Scrofula.**—Furst earnestly advocates extirpation of all accessible swollen glands when they do not promptly subside spontaneously, even when they do not seem to threaten secondary infection. If operation is refused he thinks that iodin and bromin in combination in a natural mineral water, such as the Darkauer Iodbrom water is an almost infallible means of treatment. Enlarged angry glands subside better under this treatment than under iodin salves, cod liver oil, etc. He applies to the neck or trunk compresses dipped in a quart of tepid water in which has been dissolved one dessertspoonful of Darkauer iodin salts. The compress is renewed every three hours. In case of very extensive lesions he orders a general bath with one-half to one kilo of the Darkauer salts to the bath. On suspicion of bronchial or mesenteric adenitis he gives the Darkauer water internally before breakfast, and has never observed any gastric or bowel disorders from its use.

73. **Carbonated Cod Liver Oil.**—Fürst has found that carbonated cod liver oil is assimilated much more rapidly than ordinary oil and the children fatten on it in one-third of the time. It is now produced in a durable form by impregnation under pressure, so that the carbonic acid gas does not escape when the bottle is opened. It keeps better and the taste is improved, while the digestibility and diffusion through the chyle are much enhanced.

77. **Syphilitic Heart Affections.**—Runeborg cites evidence to prove that the localization of the syphilitic process in the

heart is not a rare occurrence. It may take the form of gummatous affections of the vessels and muscle, of aortitis with dilatation and aneurismatic enlargement of the aorta, or occasionally of a valvular affection of this artery, coronary arteritis with myomalacia and connective tissue indurations (Schwielen) in the heart muscle, or it may appear as a diffuse gummatous myocarditis. The most striking symptoms are recurring pains suggesting angina pectoris, cardial asthma, uneven and irregular contractions of the heart with nonresonant heart sounds and indistinct pulse beat, and occasionally, when the orifice or valves of the aorta are involved, with accessory murmurs. In a few cases in addition to these symptoms there will also be progressive insufficiency of the heart, associated with hypertrophy and dilatation of the organ. When these symptoms develop in young or middle-aged subjects free from extensive sclerosis in the peripheral vessels, and no other cause can be assigned, there is considerable probability that syphilis may be incriminated, especially if there are suspicions of syphilitic infection even years before. Specific treatment may entail the reabsorption of recent gummatous neoformations in the vessels and heart and avert the secondary consequences and thus actually cure the patient. Even in the cases in which secondary alterations have developed, they can be improved and further progress arrested or at least postponed. Large aneurisms of the aorta and advanced gummatous or indurated myocarditis are also liable to be favorably influenced by specific treatment. In Runeborg's experience in a life insurance company, '84 out of 734 deaths were attributable to syphilis. This includes 43 deaths due to a syphilitic affection of the central nervous system, and 33 due to a syphilitic affection of the heart or aorta. In 24 of these 33 death occurred from sudden paralysis of the heart. The mortality from the central nervous system and from the heart in syphilis is, therefore, more closely parallel than is usually supposed. The parallelism becomes still more striking if we omit from the 43 "nervous" deaths the 22 due to progressive paralysis. The large proportion of deaths from heart affections is undoubtedly to be ascribed to the lack of correct diagnosis and consequently of specific treatment. Nervous affections are more likely to be differentiated and treatment instituted accordingly while there is yet time for their progress to be checked.

78. **Scleroderma in Children.**—Ebstein urges the necessity of applying the therapeutic lever in the very beginning of such affections. After the contractions and callosities are once established he knows of no means to induce their retrogression. In abortive treatment he places massage in the front rank. He describes the details of two cases. In one the affection developed suddenly in a healthy child after he had slept one hot afternoon in a damp meadow under a tree. He was hot and restless that night, but the next day seemed well, when isolated red spots appeared on one hand and arm, resembling flea bites. These spots remained unchanged for a year, when they gradually became bluish and hard and cracked. The physician who saw the red spots the day they appeared describes them as slightly raised, round spots like flat pimples, of different sizes, some almost as large as a quarter. They were redder and not so solid as the wheals of ordinary urticaria, but gradually became a paler red.

82. **Movable Heart.**—Rumpf describes a case of extreme mobility of the heart which he has had under observation for a number of years, and which has aroused much discussion. When the subject reclined on his back he experienced no discomfort, but when he lay on his side dyspnea and distress developed. Rumpf mentions parenthetically that the assumption that beer drinking necessarily entails hypertrophy of the heart, is not justified by the facts. He has examined employes of breweries who consumed ten quarts of beer a day, but performed constantly heavy manual work; and there was no hypertrophy of the heart. This was also the case with his patient, who had been in the habit of drinking large amounts of beer, but at the same time doing heavy work. He was robust and stout until he became emaciated from some cause, after which the symptoms of the abnormally movable heart developed. After he had been restored to his former weight the heart no longer slid around to such an extent, and he was completely relieved from his disturbances.

85. **Treatment of Following Head.**—Steffeck advises as a very effective and expeditious means of hastening the delivery of the head to place the woman in the Walcher pendant position and then, without regard to the position of the head or the possibility of the child s breathing, to press slowly and at brief intervals, with both hands downward and backward directly on the head of the child, as soon as the shoulders are spontaneously delivered. He describes 6 complicated cases, which he thinks establish the superiority of this method, and states that in 30 uncomplicated cases delivery was rapidly completed with all the children living.

89. **Ultimate Results of Operations for Tubercular Coxitis.**—This communication from Kocher's clinic at Berne is based on 44 cases and statistics collected from the literature, presented in tabulated form. In a previous series of 40 cases since 1893, Kocher cured 70 per cent.; in the present series of 44, 67.8 per cent. The general average is 27.1 per cent. cured in suppurating cases, the mortality 48.8 per cent. The mortality in the non-suppurating cases was 16.5 per cent., with 74.2 per cent. cured. Kocher teaches that a tubercular abscess should not be opened unless there is a prospect of removing the primary process in the bone or the causal tubercular process. The abscesses usually communicate with the joint and infection of one means infection of the other. Twenty-eight of his patients have been followed to date. The general health in all is good or very good. All limp more or less, with one exception. None use crutches, but half require a cane or high soles. Half have a good movable joint. All except 2 can walk for two to four hours without fatigue or pain. These 2 exceptions complain of fatigue after a half-hour walk. The working capacity is unimpaired in all, but 3 still have pain in the joint and a fistula persists in 2. The names of his private patients were not recorded and consequently they could not be traced, but the results presumably were superior to those of the above, as the after-care is more scrupulous in such cases.

93. **After-Sensations Following Amputations.**—One of Hilger's patients feels the missing foot like a normal foot, can move the toes and feel the contact between them. Another after amputation of a finger was still conscious of the presence of the finger, and could feel it. After removal of the dressings and visual evidence of the absence of the finger, these after-sensations vanished. From these experiences and those of others, Hilger is convinced that the after-sensations which follow amputation are the result of memory pictures of the missing organ. They have always been noticed in every case that has been under observation after the amputation, and are evidently a psychic phenomenon. In certain cases these memory pictures are prolonged by some irritation in the stump. Several cases are known in which the pain of a tuberculous knee or ingrowing nail was felt long after the limb had been amputated. He concludes that in case of failure to discover any source of irritation in the stump, psychotherapeutic measures might be successfully applied.

95. **Relations Between Syphilis and Trauma.**—Stolper emphasizes the fact that an insignificant wound may be the entering point for the syphilitic virus, and that trifling injuries may have serious results in syphilitics as the manifestations of the disease may develop at the site of a recent or long-healed traumatic lesion. Syphilitics are especially liable to spontaneous fractures and affections of the vessels of the joints. The psychic excitement of a brawl may kill a person with a syphilitic affection of the coronary arteries as surely as a blow on the chest. Stolper reviews the extensive literature on the subject, and his own experience with 20 cases. In 7 a syphilitic cutaneous muscular lesion developed at the point of the traumatism, and in 8 traumatically injured bones were the seat of the lesion.

106. **Plastic Operation for Tendon Defects.**—Hertle sutures the stumps of the tendon to a sound tendon near by, without traction. There is thus an interval between the implanted stumps in the sound tendon corresponding to the extent of the defect. After allowing three weeks for healing he slits the sound tendon to correspond to this space between and including the stumps. This leaves the sound tendon with only half its width at this point. The other half forms the connecting link between the stumps of the second tendon.

109. **Tabic Arthropathy.**—Wolde has had occasion to treat three cases and mentions that the knee was affected in more than half of the cases on record. Conservative treatment with orthopedic apparatus is superior to operation, as the joint rarely heals in a good position. A long stay in bed favors decubitus and other complications of tabes. Trauma is important, as tabetic subjects are frequently able to continue their occupation undisturbed, while an intercurrent traumatism will determine some joint affection which is liable to accelerate the course of the tabes and unfits the subject for earning a livelihood.

115. **Pancreatitis with Hemorrhage and Necrosis.**—The autopsy of the first of the three cases described showed that the inflammation in the pancreas could not have been responsible for the hemorrhage and necrosis, as the latter did not occur at the most inflamed points and sometimes was quite remote from any signs of inflammation. Neither could they be ascribed to the action of trypsin, as they occurred mostly outside of the gland. There was nothing to indicate a direct causal relation between these three processes. All three seemed to be the co-ordinated effect of some still unknown infectious agent. The acute affection proved fatal in twelve days. There was no trace of sugar in the urine at any time. The only sign to locate the disease in the pancreas was the localization of the pain at this region and its persistence. The leucocytes were always normal. The pain is important in differentiating, not only on account of its extreme intensity but for its persistence. The violent attacks of pain may also occur at a time when all the other symptoms and the general condition indicate improvement. This does not happen in ileus or peritonitis. The pain is probably due to the compression of the plexus behind the pancreas by the hemorrhage and inflammation.

118. **Adrenalin in Threatening Hemorrhages.**—With 25 c.c. of adrenalin Lange was able to save the lives of 6 patients who were threatened with death from hemorrhage. The first patient was a hemophilic young man, constantly bleeding from a cut in the thumb. The hemorrhage was checked for twenty-four hours by gelatin internally and by the rectum, but then recurred. The wound was then dressed with gauze impregnated with 50 per cent. adrenalin and the hemorrhage stopped at once. The same result followed the application of the gauze in 2 cases of hemorrhage during the changing of the dressings of an appendicitis incision. The secretion from the wound much decreased after the application of the adrenalin. Two other patients received the adrenalin internally in treatment of recurring hemoptysis or hematemesis. After taking 30 drops of adrenalin twice in two hours, the hemoptysis ceased permanently. The same effect followed in a case of morning hematemesis from a gastric cancer.

125. **Boric Acid in Internal Medicine.**—Merkel recalls that several years ago he administered boric acid internally on account of its assumed diuretic action. One to 2 gm. a day were taken in an aqueous solution by 11 patients, but never longer than for eight days. The polyuria that followed even small doses surpassed twice and three times the normal amount, and the boric acid could be detected in the urine for seventeen days after suspension. Seven of the patients complained of various gastric disturbances while they were taking it, besides colics and diarrhea. Another patient who experienced relief from local insufflation of boric acid in catarrhal affections found that an erythem always developed afterward which persisted for several days.

126. **Hepatico-Duodenostomy.**—Kehr found it necessary to resect nearly the entire length of the common bile duct on account of an annular carcinoma. The gall bladder was removed with it, and the hepatic duct just below the fork was sutured to the duodenum a short distance from the tied-off stump of the common bile duct. The patient was a man of 53 and was dismissed immeasurably improved. He tabulates the differences between carcinoma and stone of the bile duct from a clinical standpoint. Carcinoma is more frequent in men than in women; there is seldom colic, and usually icterus begins very gradually, but becomes intense and regular. The stools are constantly clay colored, although they may vary in case of a polypoid tumor. The duration of the affection does not

exceed six months. Chills and fever are rare; the cachexia is very pronounced toward the last, and the gall bladder is large and palpable in 80 per cent. There is usually ascites. His success in the case reported compels him to extend the scope of surgical intervention to cancers of the bile duct, which he has hitherto considered beyond the reach of surgery. He always recommends an operation in case of chronic icterus, which suggests an obstacle in the bile duct or pancreas, in the hope that the trouble may be merely a chronic pancreatitis. He describes his technic in the case reported, which is the first case of carcinoma of the bile duct operated on to his knowledge, and the first hepatico-duodenostomy. The dressings were soaked with bile during the first few days, but it did not proceed from the hepaticus but from the minute severed biliary passages in the liver where the gall bladder had formerly rested. He did not use a button, and left the tampon in place for two weeks. He did not tampon the anastomosis, but interposed a layer of omentum. Before performing a laparotomy on account of gallstones, he has lately adopted the practice of accustoming his patients to the use of the stomach sound, and in 50 such cases found this measure of marked benefit.

139. Concretions Found in Cortex of Kidneys.—Marchetti states that he found a number of concretions in the cortex of the kidneys of a person who had succumbed to pneumonia, with no signs of tuberculosis. The concretions resembled in every respect—even to the positive response of the nucleus to the tests for elastin—the descriptions of the bodies found enclosed in the giant cells of tubercular lesions.

140. Alleged Discovery of Germ of Rabies.—This communication proceeds from the Institute of Hygiene of the University of Pavia, of which Prof. G. Sormani is director. It announces the discovery in the salivary glands, pancreas and nervous system of animals known to be rabid or artificially infected with rabies, of a specific germ, which could be isolated and cultivated, and reproduced rabies when injected into other animals (guinea-pigs and rabbits). It stains the culture media in its growth by the elaboration of a yellow pigment, most marked on potato. It liquefies gelatin, although sometimes not until after the culture is a month old; coagulates milk and induces acidity in wine, while in broth it may enhance the original alkalinity, developing a characteristic odor. In anaërobic media it generates gas. The most characteristic cultures were obtained on a sterilized red beet, which Levy has found the best culture medium for various germs, including the lepra bacillus. The beet was inoculated with scraps of choroid tissue from the fourth ventricle of a rabbit's brain. It is usually a small sphere, .6 to 1 micron in size, and the name proposed for it is the *Blastomyces* or *Saccharomyces aureus lyssæ*. The parasite locates by preference in the pia mater, and in this anaërobic medium generates carbon oxid. It is evidently to the noxious influence of this gas on the nerve centers that a large proportion of its pathologic effect is due, as the spectrum and chemical tests revealed marked carbon oxid hemoglobinemia in the inoculated animals. This fact suggests that benefit might be derived from inhalation of oxygen in cases of hydrophobia. The photographs accompanying the communication will appear in the next issue of the *Giornale*.

146. Operations on the Biliary Passages.—Robson's paper is a general review of the treatment of morbid conditions of the gall ducts and bladder. He holds that as soon as gallstones give serious trouble their removal by operation is the most rational method of treatment, but his methods and views to some extent have been changed since his earlier work. When gallstones are once formed no medicine can relieve them, though much can be done for the accompanying catarrh; medical treatment should be thoroughly tried before surgical treatment is resorted to. It is often impossible to say what operation will have to be done and the surgeon who attempts to relieve these conditions must be prepared for whatever he may find. Robson goes into detail as to the preparation of the patient, including saline infusions in asthenia and the treatment of the tendency to hemorrhage in cholemic patients. The only special instrument he uses is the gallstone scoop. His ligatures and sutures are formalin catgut prepared by the xylol process and he uses celluloid thread for the outer and serous sutures in stitching the incision in the duct in choledochotomy. His assistants all wear rubber gloves, though he himself does not, as they interfere with his sense of touch. A firm sandbag under the patient at the level of the liver is essential. Formerly he used to make a vertical incision through the linea semilunaris, but he now always makes his incision over the middle of the right rectus in a line parallel with its fibers, which are then separated by the finger, the posterior sheath of the rectus and peritoneum being divided together. Where the gall bladder is distended and there is no jaundice, a small incision of two or three inches only may be required, but often it is necessary to explore the ducts and instead of prolonging the incision downward as formerly, he carries it upward in the interval between the ensiform cartilage and the right costal margin as high as possible, thus exposing the upper surface of the liver very thoroughly. He finds by lifting the lower border of the liver in bulk it is necessary to first draw the organ down from under cover of the ribs, the whole of the gall bladder, cystic and common ducts are brought quite close to the surface and the gall bladder is usually strong enough to endure gentle traction, which holds the parts well exposed. The surgeon then has under his eye the whole length of the ducts with the head of the pancreas and duodenum and can deal with the gall bladder, cystic and hepatic quite easily. When the duct is incised, there is generally a free flow of bile, which is almost always infected, but by rapidly emptying it out and using sterile gauze pads, the flow can be drained off without infecting the parts. After removal of the obvious concretion, he passes the finger behind the duodenum, along the course of the hepatic ducts, to feel if gallstones are there and then the common duct is incised, his gallstone scoop is passed into the primary division of the hepatic duct in the liver and down to the duodenal orifice of the common bile duct, and if thought necessary to ensure the patency of the opening into the duodenum, a long probe is passed into the bowel. Incision into the bile duct being made, it is closed by the ordinary

curved round needle and continuous catgut sutures. A continuous fine green catgut and a spun celluloid thread are employed to close the peritoneal edges of the duct. Where the gall bladder is contracted and the pancreas indurated and swelling from chronic pancreatitis is likely to press on the common duct, he inserts a drainage tube directly into the duct, passing it upward into the hepatic duct and closing the opening around it with purse-string sutures, but where this is not done and the size of the gall bladder permits, he usually fixes a rubber tube into the fundus of the gall bladder in the same way, thus shortening the area of infected bowel and avoiding pressure along the newly-sutured opening of the duct. He now never spends a long time in manipulating the impacted stone, but at once incises the duct, removes the concretion and closes the opening. Although there is seldom any fear of leakage or infection there is usually some tendency to pouring out of fluid in the first few hours. He therefore generally inserts a gauze drain through a split drainage tube, bringing it out by the side of the gall-bladder drain and usually removes it within twenty-four hours. The wound is then closed by a continuous catgut suture, first, peritoneum and deep rectus sheath, then the anterior rectus sheath, and lastly the skin margins are sewed with silkworm gut. He employs forcipressure for the immediate arrest of hemorrhage, but finds it more satisfactory to ligature the bleeding points, as in jaundiced cases the vessels are apt to bleed subsequently. If the liver is torn the bleeding must be carefully arrested before the abdomen is closed. Ordinary cholecystotomy with a distended gall bladder is a very simple operation. He condemns the so-called ideal operation of Langenbuch and the two-stage operation of Bloch. In contracted gall bladder, cholecystectomy may be necessary or advisable. The operation is described. It is easy to remove very contracted organs and use the cystic duct as a pedicle and ligature it. A method of treating the pedicle which he finds useful is to seize it with strong pressure forceps and crush it, thus making a groove in which the ligature lies very snugly. Bleeding vessels are ligated, and as a precaution a strip of iodoform is left in contact with the end of the ligated duct and brought to the surface through a split drainage tube. He has not found Dr. Mayo's operation of shelling out the mucosa of the gall bladder always practicable where there has been much inflammatory disturbance. The operations of duodenocholedochotomy and cholecystenterostomy are described. In case of malignant disease much more extensive operations may have to be done and a careful search should always be made for intravisceral fistulæ, of which he gives examples. If neglected they probably mean extravasation and death. If pyloric stenosis exists, pyloroplasty or gastroenterostomy will have to be performed. If the head of the pancreas is enlarged as a whole, causing a suspicion of malignancy, it is advisable to reserve one's opinion as there is a possibility that cure may occur as in the instance he reports. The after-treatment is a pint of saline fluid with an ounce of brandy given by enemata and 5 minims of liquor strychnia (B. P.) given subcutaneously, repeated if necessary. Beside a teaspoonful of hot water or hot tea from time to time all feeding is by the rectum for the first twenty-four hours, though more water may be given if there is no vomiting. After forty-eight hours, if vomiting does not appear, milk and soda and barley water can be freely given. After the fourth day light custards, puddings and fish and chicken on the fifth and sixth day, after which the diet becomes almost normal. The bowels are not disturbed before the fifth or sixth day, and then only by enemata, unless there is vomiting and distension. In this case a grain of calomel is administered, followed by two ounces of aperient water. He does not believe in the use of morphin under any circumstances. If a sedative is needed 10 grains of aspirin will be found useful. It should be repeated in two hours, if required. If vomiting is troublesome or epigastric distension persists, gastric lavage will be found useful. As a rule recovery is uneventful and the after-treatment for the most part negative. Stitches are removed on the eighth day, the tube coming away at the same time. The wound left, he says, heals by granulation. Only simple dressings are used. The chief point he wishes to make is that we should operate early before serious complications have ensued and that the operation should be thorough, expeditious and careful.

147. **Cholecystectomy.**—The operation of cholecystectomy is described by Moynihan as follows:

> A vertical incision near the outer margin of the right rectus muscle is made and the muscle fibers split. The usual length of this incision is 5 in. If additional room is required it is best obtained by continuing the upper end of the incision along the costal margin upwards and inwards. All adhesions of the gall bladder, ducts and liver having been cleared, the liver is rotated by gentle traction upon the gall bladder until the cystic and common ducts are straightened and brought on a level with the wound. By this maneuver the operation is rendered simpler and quicker. The peritoneal investment of the gall bladder is then cut through along the line of its reflexion on to the liver, and the gall bladder is quickly stripped from the liver and grasped in the hand, so as to exert a gentle traction on the cystic duct. A few bleeding points are occasionally seen on the denuded liver surface, and a ligature or a suture transfixing the bleeding point may be needed. A circular incision is now made through the peritoneum, at the neck of the gall bladder, and a cuff of peritoneum reflected from the neck and from the commencement of the cystic duct. A catgut ligature is tied round the duct, and the gall bladder is cut away. The mucous membrane of the severed end of the cystic duct is gently cleansed and wiped with a 1 in 500 biniodid lotion, and the peritoneal cuff is replaced and sutured. A purse-string suture may be applied over this, the first line of suture being buried when the purse-string suture is tied. No drainage tube is needed as a rule. If, however, owing to great thickening and adhesion at and around the cystic duct there is difficulty in performing all the steps indicated, and if the closure of the cystic duct is imperfect or its peritoneal hood not completely satisfactory, drainage may be provided by a split rubber tube or by a petticoat of rubber tissue packed with sterile gauze. If in any case the precise closure of the duct were impossible, I should leave a long clip on the end of the duct and drain by the side of the clip with a large split rubber tube having a gauze wick. Throughout the operation the most scrupulous attention is paid to the details of cleanliness. The viscera are carefully protected by gauze or sponge packing, and all swabs which are soiled with bile or inflammatory effusions are at once discarded. If the peritoneum be unavoidably soiled it may be wiped over with a swab wet with sterile salt solution. The hands are rinsed always in salt solution. No antiseptic is at any time allowed to touch the peritoneum.

A number of cases are reported. He mentions Mayo's operation, but does not express an opinion on it.

151. **Hemolysins.**—Ruffer and Crendiropoulo found by experiments that if the urine of a healthy man was injected two or three times subcutaneously into a rabbit the serum of this rabbit acquired a marked hemolytic action on human red corpuscles. They detail their experiments and the results. They remark that the specificity of these serums are not absolute, but this is not astonishing when one reflects that one is dealing with a liquid as complex as urine, for among the hemolysogenous substances contained in the urine there must be several common to many kinds of animals.

152. **Bottle-Finisher's Cataract.**—Robinson describes cataract as he finds it among bottle finishers, who, as a rule, have their eyes most exposed to the intense glare of the glass furnace. Only exceptionally do other workmen in the works suffer in this way. The bottle finisher has to pick out just so much melted glass as will be required to make the rim of the bottle. This takes some time, and, of course, exposure. He explains the mechanism of cataract growth being due to the special focusing on the lens of heat rays. The contraction of the pupil by the light protects the periphery of the lens at first from damage.

153. **Tuberculosis.**—Riviere reports three cases of perforation of the esophagus by tuberculous glands and remarks on its comparative rarity. He finds few instances recorded in the literature.

154. **Urea Estimates.**—Following a suggestion derived from Halliburton's Text-book of Physiological Chemistry, Pechell thought the ordinary method of estimate for clinical purposes might be improved by converting the urine to be examined into artificial "diabetic" urine. This was done by the addition of 2 c.c. of 25 per cent. glucose solution, to 5 c.c. of urine, used in Dupre's method, which gives a urine containing about 7 per cent. of sugar. Details of a few observations are given by comparing the readings thus obtained by those recorded by the same urine without the addition of sugar, a practically constant excess of one-eleventh (9 per cent.) was noticed. He can not explain the difference in the evolution of nitrogen of urea in watery solution and in urine, nor the reason why glucose increases the nitrogen output.

New Patents.

Patents of interest to physicians, etc., January 20 and 27:

718896. Electrotherapeutic apparatus. Wm. H. Ames, St. Louis, and E. E. Clement, Washington, D. C.
718594. Massage apparatus. Charles J. Bailey, Newton, Mass.
718746. Invalid bedstead. Silas W. Bennett, McDonald, Pa.
718764. Dropper for medicines. George B. Hutchings, Galveston, Texas.
718766. Massage machine. Thomas D. Ingram, Washington, D. C.
718785. Respirator. James W. McNary, Dayton, Ohio.
718801. Dropping mouthpiece for bottles. Wm. L. Straus, New York.
718958. Massaging apparatus. Fenton B. Turck, Chicago.
719175. Applicator. Henry A. Bierley and J. G. Nehrbas, Indianapolis.
719078. Supporting rest for invalids. Joseph A. Blanchard, Waterbury, Conn.
718979. Hypodermic syringe. Milton Campbell, Philadelphia.
719311. Body brace. Wm. B. Dewees, Salina, Kan.
719206. Obstetric sheet. Sarah Faulkner, New York.
719228. Disinfecting device. Louis E. Jones, Conshohocken, Pa.
719059. Litter. Joseph A. Tabor, Scranton, Miss.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., from Jan. 26 to Feb. 7, 1903:

Fletcher, Jr., Richard M., contract surgeon, U. S. A., is relieved from duty at Fort Niobrara, Neb., and will proceed to his home, Huntsville, Ala., and on arrival report by letter to the Surgeon-General of the Army for annulment of contract.

Gilchrist, Harry L., first lieut. and asst.-surgeon, U. S. A., will proceed to Fort Screven, Ga., on official business pertaining to the Medical Department of the Army, and on completion of this duty will return to his proper station in this city.

Straub, Paul F., captain and asst.-surgeon, U. S. A., is granted leave of absence for four months, with permission to go beyond sea.

Tweedie, Hedley V., contract surgeon, U. S. A., is relieved from duty in the Department of California, and will proceed to his home, Jackman, Me., and on arrival report by letter to the Surgeon-General of the Army for annulment of contract.

Arthur, William H., major and surgeon, U. S. A., is detailed as a member of the examining board convened for the examination of officers of the Corps of Engineers at the Army Building, New York City, vice Captain James Wilson, asst.-surgeon, hereby relieved.

Brown, Ira C., contract surgeon, U. S. A., now at Buffalo, N. Y., will proceed to Fort Niobrara, Neb., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the Missouri.

Kennedy, James S., contract surgeon, U. S. A., now at Chambersburg, Pa., will proceed to San Francisco, and report in person to the commanding general, Department of California, for assignment to duty.

O'Neill, Joseph A., contract surgeon, U. S. A., is directed to report in person to the commanding general, Department of the Lakes, at Chicago, not later than Feb. 18, 1903, for assignment to duty with the Fourteenth Infantry, and to accompany that regiment to the Philippines, and on arrival at Manila to report in person to the commanding general, Division of the Philippines, for assignment to duty.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Feb. 7, 1903:

P. A. Surgeon H. C. Curl, discharged from treatment and ordered to duty at the Naval Hospital, Mare Island, Cal.

P. A. Surgeon R. W. Plummer, detached from the U. S. S. *Prairie* and ordered to the Navy Yard, New York.

P. A. Surgeon F. M. Furlong, detached from the Navy Yard, New York, and ordered to the U. S. S. *Prairie*.

P. A. Surgeon L. W. Curtis and P. A. Surgeon M. B. Pitts commissioned surgeons from Dec. 2, 1902.

P. A. Surgeon M. R. Spear and P. A. Surgeon W. B. Grove, commissioned passed assistant-surgeons from Nov. 7, 1902.

Drs. L. H. Schwerin, H. T. Nelson, Jr., and C. C. Grieve, appointed acting assistant-surgeons from Jan. 29, 1903.

Medical Director W. G. Farwell, retired, detached from the Marine Recruiting Station, Philadelphia, and ordered to the Navy Yard and Hospital, Portsmouth, N. H.

Medical Director C. H. Cooke, retired, ordered to the Naval Recruiting Station, Philadelphia.

Medical Inspector J. C. Spear, retired, ordered to the Marine Recruiting Station, Philadelphia.

Surgeon Clement Biddle, detached from the Naval Recruiting Station, Philadelphia, and to continue duty at Naval Hospital, Philadelphia.

P. A. Surgeon L. Morris, detached from duty at the Naval Hospital, Philadelphia, and granted sick leave for three months.

Asst.-Surgeon J. C. Thompson, detached from duty with the Marine Detachment, Dry Tortugas, Fla., and to duty on the U. S. R. S. *Columbia*.

Asst.-Surgeon J. P. DeBruler, ordered to the Naval Hospital, Norfolk, Va.

A. A. Surgeon H. L. Brown, to duty at the Naval Proving Grounds, Indian Head, Md.

A. A. Surgeon H. W. Judd, to the Naval Station, Key West, Fla., for duty at Dry Tortugas, Fla.

A. A. Surgeon P. S. Rossiter, to the Naval Recruiting Station, Baltimore.

Asst.-Surgeon J. A. Murphy, detached from the U. S. S. *Don Juan de Austria*, and to duty on the U. S. S. *Monadnock*.

Asst.-Surgeon W. Seaman, detached from the U. S. S. *Monadnock* and to duty on the U. S. S. *Don Juan de Austria*.

Medical Inspector G. E. H. Harmon, to duty at the Naval Station, Port Royal, S. C.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Feb. 5, 1903:

Geddings, H. D., assistant surgeon-general, detailed as recorder of board to meet at Washington, D. C., for the physical examination of an applicant for the position of second assistant engineer, R. C. S.

Surgeon H. R. Carter, to report at Washington, D. C., Feb. 6, 1903, for duty as temporary member of Sanitary Board.

P. A. Surgeon Rupert Blue, relieved from duty at Milwaukee, Wis., and directed to proceed to San Francisco, and report to Surgeon A. H. Glennan for duty.

Asst.-Surgeon R. H. von Ezdorf, granted eight days' extension of leave of absence.

Asst.-Surgeon J. W. Kerr, to report at Bureau for instructions.

Asst.-Surgeon B. S. Warren, relieved from duty as recorder of board to meet at Washington, D. C., for the physical examination of an applicant for the position of second assistant engineer, R. C. S.

A. A. Surgeon E. Alexander, granted leave of absence for twenty-seven days from February 1.

A. A. Surgeon H. J. Hamilton, granted leave of absence, on account of sickness, for thirty days from December 27.

A. A. Surgeon B. Y. Harris, granted leave of absence for ten days from February 21.

A. A. Surgeon F. F. Sams, granted leave of absence for fourteen days from February 4.

Pharmacist W. W. Kolb, granted leave of absence for twenty-eight days from February 12.

APPOINTMENTS.

Henry R. Carter, appointed acting assistant-surgeon for duty at Newport News, Va.

Robert H. Gray, appointed acting assistant-surgeon for duty at Shreveport, La.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Feb. 7, 1903:

SMALLPOX—UNITED STATES.

California: San Francisco, Jan. 18-25, 8 cases, 1 death.
Illinois: Chicago, Jan. 24-31, 14 cases, 3 deaths.
Indiana: Jan. 24-31, Elwood, 2 cases; Evansville, 4 cases; South Bend, 1 case.
Kentucky: Jan. 24-31, Lexington, 12 cases; Newport, 1 case.
Maine: Biddeford, Jan. 24-31, 26 cases.
Maryland: Baltimore, Jan. 24-31, 2 cases.
Massachusetts: Jan. 24-31, Boston, 7 cases, 1 death; Haverhill, 3 cases, 1 death.
Michigan: Grand Rapids, Jan. 24-31, 9 cases.
Nebraska: Omaha, Jan. 24-31, 1 case.
New Hampshire: Manchester, Jan. 24-31, 3 cases.
New Jersey: Camden, Jan. 24-31, 4 cases; Hudson County, including Jersey City, Jan. 25-Feb. 1, 5 cases; Newark, Jan. 24-31, 2 cases, 1 death.
New York: New York, Jan. 24-31, 3 cases, 1 death.
Ohio: Cincinnati, Jan. 23-30, 12 cases; Cleveland, Jan. 24-31, 10 cases, 3 deaths; Dayton, Jan. 24-31, 1 case.
Pennsylvania: Altoona, Jan. 20-31, 6 cases, 5 deaths, imported from Pittsburg; Erie, Jan. 24-31, 9 cases; Johnstown, Jan. 24-31, 10 cases, 1 death; McKeesport, Jan. 24-31, 3 cases; Philadelphia, Jan. 24-31, 29 cases, 4 deaths; Pittsburg, Jan. 24-31, 16 cases, 6 deaths; Pottsville, Jan. 24-31, 11 cases.
South Carolina: Charleston, Jan. 24-31, 3 cases; Greenville, Jan. 17-24, 1 case.
Tennessee: Memphis, Jan. 24-31, 2 cases.
Utah: Salt Lake City, Jan. 17-24, 16 cases.
Washington: Tacoma, Jan. 18-25, 1 case.
Wisconsin: Milwaukee, Jan. 24-31, 8 cases, 1 death.

SMALLPOX—FOREIGN.

Canada: Hamilton, Jan. 1-31, 1 case; Winnipeg, Jan. 17-24, 1 case.
France: Marseilles, Dec. 1-31, 37 deaths.
Great Britain: Jan. 10-17, Birmingham, 1 case; Bradford, 35 cases; Dublin, 2 cases; Liverpool, 42 cases, 2 deaths; London, 2 cases; Manchester, 16 cases, 1 death; Nottingham, 13 cases.
India: Bombay, Dec. 23-Jan. 6, 18 deaths.
Italy: Palerma, Dec. 27-Jan. 30, 24 cases, 1 death.
Mexico: City of Mexico, Jan. 11-18, 3 cases.
Russia: Moscow, Jan. 3-10, 3 cases, 1 death.
Spain: Malaga, Dec. 1-31, 10 deaths.
Straits Settlements: Singapore, Dec. 13-20, 1 death.

YELLOW FEVER.

Colombia: Panama, Jan. 19-26, 4 cases, 2 deaths.
Ecuador: Guayaquil, Jan. 3-17, 35 deaths.
Mexico: Vera Cruz, Jan. 19-26, 4 cases.

CHOLERA—INSULAR.

Philippines: Dec. 7-13, Manila, 7 cases, 5 deaths; Provinces, 318 cases, 207 deaths.

CHOLERA—FOREIGN.

Malta: Quarantine Island, Jan. 17, 7 cases, from Alexandria.
Egypt: Alexandria, Jan. 5-12, 1 case.
Straits Settlements: Singapore, Dec. 13-20, 5 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Jan. 18, 1 death.

PLAGUE—FOREIGN.

India: Bombay, Dec. 23-Jan. 6, 341 deaths; Karachi, Dec. 21-28, 39 cases, 20 deaths.
Mexico: Mazatlan, to January 5, 60 deaths.

THE IMPROVEMENT OF GENERAL ANESTHESIA ON THE BASIS OF SCHLEICH'S PRINCIPLES:

WITH SPECIAL REFERENCE TO ANESTHOL.

WILLY MEYER, M.D.

Professor of Surgery at the New York Post-Graduate Medical School and Hospital; Attending Surgeon to the German and New York Skin and Cancer Hospitals; Consulting Surgeon to the New York Infirmary.

NEW YORK CITY.

In the writer's previous paper[1] on this subject the principal points brought out were the following:

Ether as well as chloroform are poisonous substances. We probably do not go wrong in assuming that one out of every 10,000 patients dies while under the influence of ether and one out of every 2,000 while under that of chloroform. This estimate refers only to cases succumbing on the operating table. Thus there surely is a certain amount of risk involved in every case of general anesthesia, although the exact extent of same can not be determined beforehand in the individual case.

It is this element of uncertainty as to the fate of the patient to be narcotized that has prompted many medical men, since the discovery of cocain, to discard general anesthesia as far as possible and try to get along with local cocain anesthesia. Although in the hands of an expert even major operations can be performed with the help of local (infiltration) or regional anesthesia, it nevertheless remains a fact that general narcosis can not be abolished entirely; there are and always will be many surgical interventions that can be carried out only with the patient under general anesthesia. Can the risk, which the individual patient runs in undergoing general anesthesia, be diminished?

The efforts of medical men and chemists heretofore have been directed toward finding a new, less dangerous narcotic substance as well as toward improving the chemical condition of the known anesthetics by aiming to obtain them in an absolutely chemically pure state.

SCHLEICH'S REASONING.

Schleich conducted his investigations on entirely new lines, namely, by starting from a physical instead of from a chemical basis. His reasoning,[2] based on experimental studies on animals, is briefly as follows: The amount of a narcotic substance that evaporates in a given time—barometric pressure being equal—depends on two factors:

1. The surrounding temperature, that is to say, in connection with general anesthesia: the temperature within the lungs or within the body (T. B.[3]). This is rather constant, about 100.4 F.

2. The boiling point of the narcotic (B. P.[3]), or, as one might also term it, its maximum of evaporation.

Both of these factors greatly influence the absorption into the blood as well as the elimination from it of an anesthetic introduced into the human or animal body. If a person or animal inhales an anesthetic that has its B. P. at 59 F. (15 C.), as, for instance, ethyl chlorid, it is obvious that more of the drug quantitatively is introduced into the lungs, and through these into the blood, than would be of an anesthetic that has its B. P. at 149 F. (65 C.), as has for instance chloroform.

The ability of the organism to eliminate the narcotic is increased in the measure as the B. P. of the narcotic corresponds to the T. B., provided this relation be not disturbed by a momentary firmer chemical combination. This relation can be well studied with the narcotics mostly in use to-day, i. e., ether, chloroform and ethylbromid. As experience has proved, their chemical combination is generally volatile and loose.

If the B. P. of the narcotic corresponds to or approaches the T. B., the lungs alone are capable of properly regulating the elimination of a gaseous poison. By their increased action they can prevent the accumulation and retention of directly fatal doses; exactly as much of the narcotic is exhaled during expiration as was inhaled during inspiration. This explains the fact that a deep narcosis can not be produced at all if the B. P. of the narcotic and the T. B. correspond.

If, however, the B. P. of the narcotic is considerably higher than the T. B., as is the case with chloroform, namely, 149 F., more is retained during inspiration than is eliminated during expiration. Only so much of the amount as was retained by the blood corpuscles and blood serum can be eliminated with each expiration as corresponds to the B. P. of chloroform at the temperature within the lungs, namely, 100.4 F. The superamount can not be eliminated by the lungs, physically. This must be done somewhere else within the system. Other parenchymatous organs must be called into action, i. e., heart, kidneys and liver. This explains why the after-effects on those organs are so much more pronounced after the administration of chloroform than after that of ether. It also accounts for the fact that we find no lesions within the lungs, but rather in the other parenchymatous organs of a person who died under chloroform.

In distinct contrast to these findings we notice the greatest amount of damage in the pulmonary paren-

1. Read Dec. 27, 1897, before the Medical Society of the County of New York, entitled: "The Improvement of General Anesthesia by Adapting the Boiling Point of the Narcotic to the Temperature of the Body (Schleich)."

2. Schmerzlose Operationen, II Aufl., Berlin, 1897.

3. In the following résumé of Schleich's paper temperature of the body will be indicated by T. B., and boiling point by B. P.

chyma of the lungs following the administration of sulphuric ether. Sulphuric ether, having a B. P. at 93.2 F. (34 C.) fills the alveoli of the lungs, and at their temperature of 100.4 F. must expand and thus distend the alveoli and oppose an abnormal intra-alveolar pressure to the elimination of carbonic acid gas from the blood. It is thus that the inhalation of ether disturbs respiration and immediately causes a certain degree of cyanosis. This initial cyanosis is, therefore, the consequence of retention in the blood of carbonic acid gas. Further consequences of this retention are: reflex salivation and secretion of mucus, stretching of the alveolar epithelial cells, and, in direct connection therewith, the frequent occurrence of secondary pneumonic infiltrations. The alveolar cells, when under such abnormal pressure, are not able to overcome the effects of inflammatory material which may have become aspirated. They can do so under ordinary conditions by their normal vital resistance (Nauwerck).

However, the disturbance in the intrapulmonary diffusion of gases gradually becomes regulated. The partial pressure of the carbonic acid accumulating within the blood gradually reaches and partially overcomes the tension of the ether vapors within the alveoli sufficiently to permit its escape from the blood into the same. The cyanosis disappears with the initial carbonic acid asphyxia and the true ether narcosis begins. But the carbonic acid within the alveoli still encounters an abnormal resistance from the ether which is constantly pouring into the lungs. The complete escape of carbonic acid gas in expiration is, therefore, obstructed. The gas gradually accumulates in the lung parenchyma and at a certain tension its intra-alveolar pressure helps to force the ether into the blood. It is this gradual increase of the pressure of the carbonic acid gas within the lungs that enables the blood to retain a certain amount of ether. Although elimination of ether is almost equal to its absorption, it is the slight excess that remains in the blood which suffices to affect the brain and produce unconsciousness. The greatly accelerated rhythm of breathing, which increases the amount of oxygen entering the blood, facilitates the elimination of carbonic acid by the laws of diffusion of gases involved in normal respiration. Incidentally the elimination of ether is also facilitated. For this reason death from ether on the operating table is almost impossible as long as respiration is efficient.

On the other hand, all these processes just described account for the fact that ether narcosis sometimes has such deleterious effects on patients suffering from lung trouble. The primary and only condition for the regular elimination of the ether vapors is an absolutely intact lung—a lung that is able, if necessary, to do more than the usual amount of work.[4]

To sum up: Schleich believes that it is only on account of its high B. P. that chloroform, when administered for narcosis, is absorbed by the blood to a greater extent than is needed for the purpose. It, moreover, leaves the organism only by degrees. In doing so it overtaxes all the parenchymatous organs, thereby injuring their cells. Ether, on the other hand, with its B. P. at 93.2 F. (34 C.), is converted into vapor so rapidly when inhaled into the lungs with their temperature of 100.4 F., that it would not enter the blood at all—loosely bound as it is—if the alveoli did not first become overfilled with carbonic acid gas, producing primary cyanosis and dyspnea. It is with the help of this cyanotic attack that, it seems, the narcotic effect of the sulphuric ether begins.

4. Whether this physical reasoning of Schleich is correct *in all its details*, I do not propose to discuss here.

ANESTHETIC MIXTURE.

Being personally convinced of the correctness of these deductions, supported as they were by the results of his experiments on animals, Schleich started his research for the purpose of finding a narcotic, the B. P. of which would correspond to the T. B. That is to say, he wanted to find a safe and inexpensive narcotic of which the amount eliminated during expiration would almost equal that absorbed during the previous inspiration. If this could be accomplished, such new narcotic substance would not—Schleich felt confident—share the annoying effects of ether and chloroform when administered alone, nor the many dangers involved as regards the patient. Such new anesthetic could be found in a mixture only.

The use of mixtures of ethereal substances for general anesthesia is nothing new in the history of anesthetics. Thus the English have had their A.C.E. mixture of world-wide fame for the last thirty-three years. At Vienna a mixture of one part of chloroform and six parts of ether has been used so extensively as to be known for a long time as "the Vienna mixture." The late Professor Billroth of Vienna used a mixture of one part of ether and alcohol each and three parts of chloroform. These mixtures were liked and praised by many; they were absolutely denounced as ineffective, dangerous, etc., by others. Kocher of Bern stated that he never permitted the use of the latter mixture in his clinic, because he was sure that in administering it to patients a small quantity of chloroform, of ether and of alcohol would be absorbed. He declared himself opposed to mixing narcotics. In an article by an American writer[5] we find the following words: "Against such mixtures the argument has always been urged that a new chemical is not thus made with a single rate of diffusion; and that, while the rate of relative evaporation is doubtless in part modified by the mixture, the patient substantially gets first ether, then chloroform, then alcohol, in order of volatility. The writer agrees with the majority of authors in feeling that a gain in security is not made thereby. 'Straight drinks' are the safest, to speak after the manner of the world."

Correct as this may seem theoretically, in practice mixtures have proved safer than ether or chloroform alone. Our English colleagues have reported 15,000 cases of major anesthesia with the A.C.E. mixture without a single death. It is also stated from Vienna that there have been 8,000 administrations of the Vienna mixture without a death. The reason for the greater safety of the so-called mixtures, according to Schleich's investigations, consists in the fact that they are chemical solutions—not mixtures—having a new B. P. different from that of any of the components. Thus the B. P. of the A.C.E. mixture is about 119 F. (49 C.), certainly a good deal nearer the T. B. than chloroform, with its B. P. at 149 F. (65 C.). Schleich was the first to make this assertion.

SCHLEICH'S EXPERIMENTS WITH MIXTURES.

On the basis of this conviction, Schleich experimented with different ethereal substances with a view to finding a mixture the B. P. of which would correspond to the T. B. After considerable experimenting he at last selected ether, chloroform and petrolic ether (that is, benzine). The latter's action, as Schleich maintains, is indifferent, as far as its narcotizing effect is concerned.

5. R. H. M. Dawbarn: General Considerations on Major Anesthesia, etc., New York Polyclinic, April and June, 1897; Atlanta Medical and Surg. Journal, August, September and October, 1897.

It is used for the purpose of diluting the chloroform, that is to say, for the purpose of diminishing the latter's poisonous effects on the system. In order to be effective it must have its B. P. almost equal to that of chloroform, about 149 F. (60-65 C.). Schleich makes the following postulates:

1. By so mixing various ethereal substances the resulting fluid is a real solution in a chemical sense;[6] a new fluid, a new narcotic, if you so wish, and not a mixture of different ethereal substances which evaporate each, individually.

2. By changing the proportion of the components we can change the B. P. of the solution at will, according to necessity arising in a given case. We can thus individualize, i. e., we can in a given case adapt the B. P. of the narcotic to the T. B. as the thermometer may have shown before operation.

3. These facts hold good and are verified in regard to cold-blooded as well as warm-blooded animals. Frogs and crabs did not react differently from doves, rabbits and cats with reference to an anesthetic, the B. P. of which did not correspond to the T. B.

4. The result is the same, no matter whether the solution be inhaled, given per rectum or injected subcutaneously.

5. In administering the solution to the human subject the results are exactly the same as those observed in animals.

The possibility of changing the B. P. of the new anesthetic mixtures at will induced Schleich to recommend three different mixtures, their proportion to be based on the facts mentioned above: that the higher the B. P. of a narcotic the slower will be the process of elimination from the system. Schleich thus made three standard mixtures of the following composition, prepared by volume, not by weight:

Chloroform	45 cc.=1½ oz.	45 cc.=1½ oz.	30 cc.= 1 oz.
Sulphuric ether.	180 cc.=6 ozs.	150 cc.=5 ozs.	80 cc.=2 2/3 ozs.
Petrolic ether...	15 cc.= ½ oz.	15 cc.= ½ oz.	15 cc.= ½ oz.

THE AUTHOR'S EXPERIENCE WITH PETROLIC ETHER.

The paper comprising the foregoing points, also my clinical observations made with Schleich's original mixtures in 100 cases, and read before the Medical Society of the County of New York on Dec. 27, 1897, never appeared in print. A rather extensive report of the same, however, can be found in the New York Medical Record, Jan. 8, 1898, furnished by one of the reporters of that journal, who had been present at the meeting. The reason for my not publishing the paper I will briefly mention here:

Schleich's mixtures, as just stated, contain chloroform, ether and petrolic ether, the latter being benzine with a B. P. of 60-65 F. (15-18 C.). Petrolic ether being a substance which I had never heard of as possessing anesthetic properties, I asked Dr. S. J. Meltzer of this city, the well-known physiologist, a few weeks before I presented the above-mentioned paper, to oblige me by making some animal experiments in order to ascertain the action of this agent on the animal organism. In a letter received from Dr. Meltzer,[7] under date of April 13, 1898, he stated: "According to my experiments petrolic ether, as used in Schleich's mixtures, if administered pure, has no narcotizing effect at all, but produces in rabbits and guinea-pigs convulsions, soon followed by tetanus and opisthotonus; if the inhalation be continued the animals die with symptoms of tetanus. If petrolic ether is administered in combination with sulphuric ether, the resulting paralysis remains unchanged. The conclusion seems justified that if this mixed narcosis were extended the animals would most probably die of paralysis of the respiratory muscles."

Petrolic ether, as stated by Schleich, was added in order to reduce the effect of the chloroform in the mixtures "for the purpose of dilution." The small amount of petrolic ether in these mixtures—1/16 to 1/8 per cent. of the entire volume—explains, it seems to me, why those who had employed Schleich's anesthetic mixtures did not meet with deplorable accidents in some of their patients.

Shortly before I received Dr. Meltzer's communication, my friend, H. P. Weidig, Ph.D., of Newark, N. J., an expert chemist, found, on analyzing these mixtures, that they contain a permanent nucleus—a chemical combination of chloroform and ether according to their molecular weight. Chloroform has a molecular weight of 119.5; sulphuric ether, 74. Thus, 119.5 grams of chemically pure chloroform and 74 grams of absolute sulphuric ether, or, expressed in volume: 43.25 parts of chloroform and 56.75 parts of ether mixed together, enter into chemical combination, which truly represents a new anesthetic. It contains neither free ether nor free chloroform and has a B. P. of its own at 125.6 F. (52 C.). We called this product "molecular solution" (of chloroform and ether), or abbreviated, "M.S."

I would emphasize that this finding of Dr. Weidig's of a true chemical combination of chloroform and ether according to their molecular weight, constitutes a hitherto unknown chemical fact, as it seems, a fact which I consider to be of great practical importance.[8]

Schleich's mixtures, according to Dr. Weidig's investigations, contain this fixed molecular solution of chloroform and ether (M.S.) plus 36 to 53 per cent. (in volume) of free ether, plus petrolic ether, the latter most probably not in chemical combination. Therefore, our patients when subjected to general anesthesia by means of Schleich's mixtures, in the beginning of the narcosis inhale pure ether plus M.S. plus petrolic ether. As soon as the ether and petrolic ether, which are not in chemical combination, have evaporated—and this will probably soon be the case—the narcosis continues with M.S. In other words, in the administration of Schleich's mixtures the anesthetic was adapted to the temperature of the body at the beginning of the narcosis only; soon after the latter was continued with one of a higher B. P., 125.6 F. (52 C.).

THE ABANDONMENT OF PETROLIC ETHER.

These physiologic and chemical facts, established through our efforts here in New York, convinced me of the inadvisability of continuing the Schleich's mixtures for purposes of general anesthesia, and prompted me to withhold from publication the paper I had read on the subject—a paper which had been written for the sole purpose of bringing before the profession the supposed advantages of Schleich's mixtures. On Dec. 27, 1897, I proclaimed these mixtures, on a basis of my personal clinical experience, before a large audience of medical men as "having come to stay," and now, three months later, in view of these absolutely unexpected revelations, I felt in duty bound to abandon their use!

6. This is not in accordance with the result of the chemical analysis made by Dr. H. P. Weidig, which see later.

7. Conf. author, N. Y. Med. Rec., 1898, p. 607, "Schleich's Mixtures for General Anesthesia."

8. It is not claimed, that ether and chloroform form a new body, such as, for instance, acetone and chloroform do. The term "chemical combination" is, used in the sense that the two components, chloroform and ether, dissolved in each other in molecular proportion, will resist fractioning by distillation to the last, i. e., this molecular solution of chloroform and ether has an evaporating point of its own.

However, I parted from them with sincere regret, for I had been charmed with their effect. During sixteen weeks of continuous use in my surgical work in private and hospital practice the narcoses with these mixtures had been so uniformly good that I was convinced that the improvement in general anesthesia, so much sought after, especially in regard to our daily practice, would have to be looked for principally in the direction of physical improvement of general anesthesia rather than in the chemical improvement of anesthetics. I therefore determined to try to find a mixture that would contain neither petrolic ether nor free ether, and yet have a boiling point corresponding to the temperature of the human body.

It was due to the invaluable and continued assistance of Dr. Weidig that I was enabled to successfully pursue the task I had set for myself. During the time of experimentation (the first part of the year 1898) I administered M.S. for general anesthesia and found it to be an excellent narcotic.[9] I might mention parenthetically that M.S. is still used by a number of surgeons at the German Hospital.[10]

THE ORIGINATION OF ANESTHOL.

As stated before, the B. P. of M.S. is 125.6 F. (52 C.). Now, if Schleich's reasoning were correct it was clear that if M.S. could be modified in such a way as to give it a B. P. at 100-104 F. (38-40 C.), such modified anesthetic—being in absolute conformity with Schleich's principles—would be still safer than M.S. and represent at the same time the logical mixture for general anesthesia. After considerable experimenting it occurred to Dr. Weidig to try the admixture of ethyl chlorid, which has a B. P. at 59 F. (15 C.) and M.S. He found that a mixture of 18 per cent. volume of ethyl chlorid plus 82 per cent. volume of M.S. has B. P. at 100.4 F. (38 C.); 17 per cent. volume of ethyl chlorid plus 83 per cent. volume M.S. has B. P. at 104 F. (40 C.); 16 per cent. volume plus 84 per cent. of ethyl chlorid volume of M.S. has a B. P. at 107.6 F. (42 C.).

Considering it unnecessary to make so fine a distinction I proposed that the first and third mixtures be dropped and the second one only be used, viz., 83 per cent. volume of M.S. plus 17 per cent., volume of ethyl chlorid, which has a B. P. at 104 F. (40 C.), thus employing one and the same mixture for all cases. Just at that time the anesthetic properties of ethyl chlorid as such were published by R. Ludwig[11] and G. Lotheissen.[12] The success and lack of accidents in the employment of pure ethyl chlorid for general anesthesia, as brought out in these articles, gave me sufficient courage to test Dr. Weidig's new mixture in the living without previously experimenting on animals. This new mixture we termed "anesthol."

THE FIRST USE OF ANESTHOL.

I used anesthol for the first time Oct. 15, 1898, in an interval operation for appendicitis. The narcosis and its sequelæ were all that could be desired, equal to the best I had seen from the use of Schleich's mixtures. Since that time I have used anesthol almost exclusively in all my operations requiring general anesthesia, in hospital as well as private practice, that is, for a period of nearly four years. The only exceptions were such operations on the face where I deemed pure chloroform preferable.

DESCRIPTION AND PROPERTIES.

Anesthol is a clear, transparent fluid of very agreeable odor; it has a sp. gr.[13] of 1045 and a B. P. at 104 F. (40 C.). It is a chemical combination of ethyl chlorid and M.S., not a mixture; for, on evaporating 1000 c.c. of anesthol for five hours at a uniform temperature of 104 F. (40 C.) 22 c.c. (2.2 per cent. volume) with a sp. gr. of 1,262, were left. The sp. gr. of chloroform is 1,490. This fact proves that up to the last moment a "solution of components" discharges and does not leave a final residual chloroform, the narcotic with the highest B. P., as is the case in Schleich's mixtures (Weidig).

The analysis with regard to the actual quantity of each of the three drugs contained in anesthol according to volume, as made by Dr. Weidig, showed that anesthol contains 17 per cent. of ethyl chlorid, 35.89 of chloroform and 47.10 per cent. of ether, representing as will be seen, a proportion of about 1:2:3. It certainly is of interest and worthy of note that the proportion of the renowned English A.C.E. mixture is the same. The latter, however, was constructed in an empiric way, while anesthol is based on scientific principles, being the result of an attempt at adapting the B. P. of an anesthetic chemical combination of chloroform and ether, M.S., to the temperature of the human body. After this had been accomplished on a strictly scientific basis the resulting new anesthetic chemical combination of ethyl chlorid, chloroform and ether (anesthol) was analyzed with the above stated result.

Any one can, of course, prepare anesthol; it is not patented. It is put up in 4, 8 and 16 ounce bottles. It can be had at the principal drug stores.[14]

(To be continued.)

9. Conf. N. Y. Med. Rec., April 23, 1899, p. 607.

10. Braun of Leipzig favors a mixed narcosis of ether and chloroform, both administered at the same time, but each individually, by means of a special apparatus, not, as we did, both at the same time in chemical solution on one mask. (Report of Congress of German Surgeons, Berlin, 1901.)

11. "Ueber Narkose mit Aethylchlorid," Beitr. z. Klin. Chir., vol. xix, p. 639, 1897.

12. Arch. f. Klin. Chir., vol. lvii, p. 865, 1898. See also: M. W. Ware, "One Thousand Personally Conducted Cases of Ethyl Chlorid Narcosis," paper read before the Section on Surgery and Anatomy, of the American Medical Association, Saratoga, 1902. THE JOURNAL A. M. A., Nov. 8, 1902, p. 1160.

13. I might state here as an interesting fact that the specific gravity of anesthol is very near that of the human blood, viz., 1,056-1,059, certainly nearer than that of any other anesthetic in use.

14. Personally, I have always procured anesthol of Messrs. Chas. Cooper & Co., 194 Worth St., New York, of which firm Dr. H. P. Weidig is a member. It is prepared under the latter's personal supervision. Its purity and correct composition are guaranteed. In order to insure results that will be of value in drawing conclusions from the observations of others, I would strongly urge that anesthol of this manufacture only be used.

SOME NOTES ON AURAL VERTIGO.*

B. ALEX. RANDALL, A.M., M.D.
PHILADELPHIA.

Aural vertigoes have attracted a great deal of attention, especially of late years, yet they constitute a very little known field of our work, while their serious inconvenience or their actual disablement of the patients render them of great practical importance. Like the matter of subjective noises in the head the causation is so multiform that each case presents a problem of considerable difficulty and demands close and discriminating study in order to locate and improve the condition. Advance in this direction has undoubtedly been made by those who have laid stress on the tympanic origin of many of these cases, except when they have ignored or belittled the other elements of etiology and have assumed, because cure has been occasionally reached by

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. Emil Mayer, C. R. Holmes and G. H. Makuen.

procedures directed to the tympanum, that no labyrinthin cases exist. "Menière's disease" as a distinct entity has certainly suffered much eclipse of late years and our views on the subject have expanded; but the narrowness of view, which would exclude it wholly from consideration as a complex of symptoms due to labyrinthin involvement, is certainly little calculated to advance the general understanding of the subject.

Especially since the grippe epidemic of the last ten years cases of labyrinthin involvement have been not infrequent, and a history such as that of the following case can leave little doubt as to the nature of the lesion. A trained nurse, 25 years of age, awoke one morning after a period of entire health to find herself too dizzy to lift her head from the pillow, falling back helpless at the effort and becoming nauseated by the rotation of everything about her. The left ear was totally deaf, without discharge, pain or other involvement. The condition grew better after some days in bed and at my first examination I found only moderate vertigo and no hearing on the affected side for any tone from the lowest to the highest. Under alterative measures she speedily recovered and was able to resume her duties. Her hearing returned for all notes of the Galton whistle (some 40,000 down to 4,000 double vibrations per second), but below this point she remained absolutely deaf to all tones and was therefore unable to hear any speech in this ear. No evidence of tympanic disease was at any time present and the lesion was probably hemorrhagic and undoubtedly in the upper turns of the cochlea.

Politzer[1] says: "For the differential diagnosis between the labyrinthin form of Menière's symptom-complex and that due to middle-ear affection, the tuning-fork tests are of importance. If the Rinne test is positive in advanced defect of hearing, the duration of perception of the fork-tone through the bone shortened, the loud watch-tick unperceived by bone conduction, while deep tones are well heard by air conduction, no doubt underlies the diagnosis of a labyrinthin affection."

It is in these labyrinthin cases that our testing of hearing by tuning forks and other methods must be complete and precise, and in these, therefore, the limitations and uncertainties of these tests will come most conspicuously to notice. The tuning forks may elicit contradictory and valueless responses from our patients and show the fallibility common to subjective tests; yet the judicious employment of a sufficient variety of tones should bring the matter fairly within the control of the examiner and explain or eliminate many of the contradictions. Those who have employed but a single fork and endeavored thereby to discriminate between tympanic and labyrinthin affections are generally confessedly unable to afford us any clear criteria for their views, which they claim empirically to have verified; but this must not discourage us from the more thorough study of the range of hearing and the relation of sound conduction by air and by bone as a means of learning the truth in these matters and better deciding our lines of treatment.

The severe cases of aural vertigo are certainly rare and the number seen even in extensive practice will always form but a poor basis for any sweeping dicta as to the general subject; and the differences which are encountered by different men will always present illustrations of the two sides of the shield and the importance of the point of view of the observer. It will fairly define my own position if I say that in the past ten years I have been seeking cases suitable for relief by intratympanic operation, and in upward of a hundred cases have met but a single one in which I could feel justified in operation for the relief of pressure on the stapes, and this in a woman of utterly neurasthenic type, who was notably relieved at first by catheter inflation. She has been anything but a brilliant example of the benefits of operative treatment, and would probably have been as much helped by the anchoring of her floating kidney as she claims to have been only after months by the operation on the incus. In the great majority of the cases of vertigo which have come under my observation neurotic and general vasomotor influences have seemed largely at fault for the symptom, except in the considerable group in whom the catarrhal affection of the eustachian tubes and tympanum was so clearly at fault that treatment by the catheter directed to this condition could be fairly expected to give the relief which was obtained.

In the neurotic individual benefit by the catheter may be at first also notable; but the strain of its employment tells unfavorably on their impaired physique, and continuance of the procedure is unwise or detrimental. Its influence must, therefore, be considered similar to that of any impressive measure whether operative or not, and to whatsoever part directed, and is ascribable more to emotional shock than to any physical or physiologic change of relations.

It is as to the third group of generalized vasomotor conditions that I feel that I may offer some suggestions rather constructive than destructive. Some of these cases present a nearly typical Menière attack, with tinnitus, vertigo, deafness and unconsciousness; but some of the worst instances lack one or the other of the most characteristic elements and the impression has a transitory character, which excludes all probability of notable physical change. Even the serous exudation into the labyrinthin structures, which Gruber has urged as the causation of many aural vertigoes, can hardly be assumed for conditions which are so sudden in onset and so immediate in recovery; and the perfect hearing which persists in some of these cases, although the attack is severe enough to fell them as though struck by a hammer, raises the question as to whether the lesion is not wholly central. Its vasomotor causation is rarely in doubt and moderate arteriosclerosis is fairly discernible in most of these cases. The therapeutic test well bears out this view of their etiology, and medicaments directed to improve the vascular condition, the iodids and other absorbents, strychnia, quinia and other vascular tonics, but especially the adrenal extract, have given me a notable gain in many of these cases which had proven stumbling blocks to previous attendants. Combination of the various elements is to be expected in many cases, and our therapeusis and regimen must be judiciously directed to the needs of the individual; but I desire particularly to direct attention to the value of adrenalin for the forstalling of these attacks and building up of that self-confidence which is often so seriously impaired in the subject of such a disorder. It is needless to go into any disquisition on the physiologic effect of this potent addition to our remedies, nor is it needful to point out its usual antagonism to nitroglycerin and the need for tentatively employing these opposed medicaments quite empirically in some instances. Yet it may be generally laid down that in the cases of marked vertigo of transient and otherwise undeterminable causation the adrenal may be expected to steady the circulation of the premonitory phase of the

1. Text-Book, Fourth Ed., p. 601.

trouble and prevent the occurrence or greatly abate the severity of the vertiginous attack. Its cautious employment for this tonic as well as prophylactic effect has been most happy in a number of cases which had yielded to no other line of treatment and in some of which the experimental use of nitroglycerin had greatly increased the disturbances.

I would recommend, therefore, that in all cases of vertigo coming to the otologist he should employ minute methods of study as to the tympanic and labyrinthin condition, but also investigate personally or through the aid of a judicious physician all the general aspects of his patient's case. He should exclude or relieve all involvements of the accessory nasal cavities, investigate the refraction and muscular relations of the eyes, as well as learn whatever teaching may be given him by the eye-grounds and, abating nothing of the local treatment by inflation and massage, which the aural condition may seem to demand and using strychnia and other tonics according to the general needs of the patient, he may yet employ as a direct and almost specific means of treatment this vigorous vascular tonic, which has been given us in the adrenal extract.

DISCUSSION.

DR. GEORGE L. RICHARDS, Fall River, Mass.—I have at the present time a troublesome case of aural vertigo, which illustrates one phase of which the Doctor spoke. This man improved for a number of weeks under the catheter and aural massage in connection with such general treatment as was given him by his family physician. But now the period of improvement seems to have passed, and I am not apparently doing him any good. Given a sudden change of temperature from warm to cold and an attack may come on at any time. He is better under continuous warm weather, and he has gone south for a number of winters. Our New England temperature is so changeable that he has never dared to go away from home without taking his wife or daughter with him, for several years, for fear of being overcome with an attack when alone.

DR. C. H. BAKER, Bay City, Mich.—I think the author of the paper made the statement that a case he mentioned was probably hemorrhagic and that the lower tones were lost so that the patient did not recover the power of hearing speech, and I think he gave that as an indication that the hemorrhage was in the upper convolutions of the labyrinth. I was under the impression that the destruction in the lower portion of the labyrinth causes impairment of the lower tones and that the higher tones are disturbed by the involvement of the upper portion. As to the case mentioned by the last speaker, the effect of sudden lowering of the temperature would be to raise the blood pressure by contracting the arterioles, and there I would think adrenalin would be contraindicated, since it would practically do the same thing, and nitroglycerin, from theory, we would expect to be more beneficial. The most distressing case of this disorder I have seen occurred in a man so youthful that it could hardly be thought of as a case of arteriosclerosis. Before the vertiginous attacks began he had symptoms of tinnitus, without impairment of hearing. He has now apparently lost the hearing. The bone was apparently undergoing hyperplasia and filling up the canals, the pressure destroying the activity of the nerve elements.

DR. RICHARDS—In my case, the patient always had nausea with the attacks.

DR. SARGENT F. SNOW, Syracuse, N. Y.—I wish I could have heard this paper before, for I had a case last summer in which I believe adrenalin would have been of much temporary benefit, which probably is all the Doctor hopes for from its use. The chief thing to think of is the removal of the cause, and eustachian destruction is often the main factor of these vertigoes. In the last year I have had two cases. In one case, a woman, the only abnormal condition I could find was some enlargement of the middle turbinates. She could not stay for prolonged treatment, but could have some operative work done. Removal of the turbinates was followed by a cure, and there has been no return. The other case was a man, about 55 years of age, with such intense vertigo that at times he had to be led about the street. He also had obstructed eustachian tubes. I removed the turbinates without avail. Looking further into the condition of the man, I found the whites of the eyes very yellow and the other general appearances that go with a torpid liver. I could get no results that remained at all constant until his liver was aroused. At first I gave him a good sized blue mass pill twice a week and later every week. The eustachian tubes in this case, as well as the first, were obstructed, but this has now cleared up.

DR. GEORGE M. CASE, Elmira—I think Dr. Snow has well represented the condition of affairs. We have not only to look to the local conditions but also to the constitutional conditions. My experience in the treatment of aural vertigo is that you will often find a toxemia or a lithemic condition. A great many of these cases would be relieved by the combined treatment. If we attempt to cure them by only relieving the stenosis of the nose and eustachian tube, we will often fail. It is noteworthy that in many cases of tinnitus and vertigo the constitutional condition is an important factor. In the great majority of cases in plethoric patients I use pilocarpin. Of course, I suppose adrenalin might take the place of it as a temporary expedient.

DR. C. R. HOLMES, Cincinnati—This is a subject of great importance, because we encounter it so frequently. I have had a few cases of severe vertigo. In fact, I have the records of three cases with epileptoid seizures, which were entirely relieved by opening the eustachian tube. One man, in particular, who was entirely deaf from childhood, began having these attacks. On his way to Cincinnati he had two attacks. While sitting in the car he slipped off the seat. He had attacks similar to those of epilepsy, but without the biting of the tongue. They were relieved by opening the eustachian tubes, but they recurred until the general condition was looked after. I now never undertake the treatment of a case without going into the patient's manner of living, to find the conditions that it may be necessary to correct, such as the method of living, eating, drinking and clothing. I have printed, for the benefit of my patients, slips, which I hand to them that they may not need to ask me a lot of questions, the answers to which they will forget. I give these slips to all my nasopharyngeal and aural patients. I think the general treatment is of vast importance.

DR. J. C. BECK, Chicago—I have in mind one case of aural vertigo in which no trouble was found in the nose or throat. I could clearly obtain the history of specific disease. The patient does not need to reach the usual age of arteriosclerosis to have that condition after syphilis. We find many cases of vertigo are syphilitic in nature, and, therefore, constitutional treatment is certainly called for. Iodid of potassium and the thorough use of mercurial inunctions cured my case.

DR. B. A. RANDALL, Philadelphia—When my paper is read I think the gentlemen will note that the constitutional conditions are fairly gone into, and that I am almost as bad as Haig in attributing to gout and the uric acid diathesis every ill that flesh is heir to. The point made by Dr. Snow is good, that the effect from the adrenal is temporary; but it is often important to get the effect quickly, even though only temporarily, to meet the crisis that is imminent in these cases. We may give the adrenalin chlorid if the aura is very short and no time remains for the slower absorption of the powder, but otherwise the desiccated adrenal or its solution should be used, for with it a more prolonged effect can be secured. If we contract the vessels with adrenalin we may expect some reactive expansion in most cases, and we must meet this with strychnia and other tonics. But the promptness with which the adrenalin can act in the stage of aura or prodrome, which is recognized in not a few of these cases, enables us to permit them to walk abroad like free men and women and that is no small gain. As to nitroglycerin, it is distinctly indicated in some of the very flabby neurasthenic cases, who will improve very much

under its employment and lose the dread of vertigo. But, on the other hand, one of my patients, a gentleman who seems to have been so pleased with the effect of the adrenal that he has been sending me patients ever since, was apparently made worse by the employment of nitroglycerin. He is distinctly neurotic. He is one of the type who can ride in an automobile or trolley without catching a cold, but is stuffed up at once when he rides behind a horse. Of course, these cases are known, but they are relatively rare. Whether these cases are rheumatic or due to some other intoxication, they are subject to easy impression, and the use of adrenal is of special value.

I need hardly answer the point raised as to the structure of the cochlea, which entails the disputed Helmholtz theory and is one of the paradoxes of the auditory apparatus, of which we have so many. In the first turn of the cochlea, where the tube and the expansion of the bony lamina is at its broadest. the basilar membrane of the cochlea is at its smallest. Where all the other parts of the cochlea are smallest, the fibers of the membrane are longest, and here at the apex the lower tones are heard, while the high tones are heard in the lower portions of the cochlea.

TRANSILLUMINATION OF THE NASAL ACCESSORY SINUSES DURING ACUTE CORYZA.*

CAROLUS M. COBB, M.D.
BOSTON.

Transillumination of some of the accessory sinuses has been one of the stock tricks of traveling showmen for many years, and in every village where they exhibited a few of the more daring boys learned to make "fire come out of the eyes," and were a decided nuisance with it until something else took up their attention. That a lighted taper held in the closed mouth would, under proper conditions, illuminate the pupils of the eyes has probably been known for many years, but it was not known that the phenomenon was of any practical importance as a means of diagnosis until Voltolini of Breslau published the results of his experiments in 1888. In 1889 Heryng of Warsaw elaborated these experiments and placed transillumination on a practical working basis. Brown Kelly of Glasgow first called attention to the fact that the rays of light entered the eye and could be perceived by the patient. This was in 1892, and his observation was shortly followed by similar ones by Garel of France and Burger of Germany. Davidsohn called attention to the fact that if the eyes were opened during the experiment a dull red reflex could be seen in the pupil, and in a scientific way we have made useful, as a means of diagnosis, the trick of the traveling showman which was copied by the small boys of making "fire come out of the eyes."

In transillumination of the antrum of Highmore the rays of light pierce the hard palate, and first enter the nasal chambers and from there through the external nasal wall to the antrum, and then through the roof of the antrum, which is the floor of the orbit, and then the coats of the eye, and so become visible as a dull red reflex in the pupil. It is evident that this is the course of the light, for in a vast majority of the cases the floor of the antrum does not extend over the hard palate far enough for the rays of light to enter it directly. The floor of the antrum is generally just above the alveolar process, and therefor light would meet with less resistance in following the route as given above. The course of the light leads to a source of error which we will call attention to later.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. Emil Mayer, C. R. Holmes and G. H. Makuen.

MEANS OF ILLUMINATION.

To obtain satisfactory results it is necessary to have a dark room and an electric lamp of sufficient candle power. The dark room is generally easy to get, but it has been my experience that it is not so easy to obtain electric lamps of the requisite candle power. When I first began to transilluminate the sinuses I was not at all satisfied with the results which I obtained, and during my investigation to find the reason for my unsatisfactory results I took my lamps to the General Electric Company and had the candle power measured. I found that lamps which I had bought as two and four candle power were all less than one, and some of them of less than one-half candle power. I have had the same experience when I have bought lamps of instrument dealers, until I have come to the conclusion that they make no effort to ascertain the candle power of the lamps which they sell. One reason for the lack of illuminating power of the lamps ordinarily sold for this purpose is that they are too small and it is absolutely impossible to get sufficient light from these toy lamps. Lamps of sufficient power can be obtained from reliable manufacturers of electric lamps, but they are quite likely to sell you what you ask for, and if you demand a small lamp you will get as efficient a lamp as can be made in that size, but probably it will not be what you want for the work. Even if it is fairly satisfactory for a time, it will soon lose its efficiency and be worse than useless because the results obtained will be unreliable.

TECHNIC.

The technic of transillumination of the accessory sinuses is very simple, provided that you have lamps of sufficient candle power, and by its use we may get confirmatory evidence in regard to the condition of the antrum and frontal sinus. We can compare the two sides, and, what is of more importance, we can compare the condition of the sinuses, as shown by the light reflex, at different stages of an acute attack. The method which I have used for transillumination of the antrum is to have the patient hold a four or five candle-power electric lamp in the closed mouth, being particular to have the lamp held as nearly horizontal as possible. If the antrum is healthy this will usually give the light crescent under the lower lid and the red reflex in the pupils. I have not had sufficient experience with the method of Escat to form an opinion of its merits. His method, briefly, is to carry an electric lamp protected by a metal funnel, to the outside of the antrum, between the cheek and the external wall of the antrum. It is claimed for it that it gives the same results as the other method, and that it overcomes a source of error, i. e., the obstruction to the passage of the rays of light caused by growth, hypertrophies or deformities in the lower meatus. The frontal sinus is illuminated by pressing a small electric lamp, protected by a hood, against the inner angle of the orbit, just below the superciliary ridge. All of the members of this Section are perfectly familiar with the sources of error in transillumination, and I shall call your attention to only one, which can, with a little care, ordinarily be overcome. The one to which I allude is the effect that blocking of the lower meatus may have in preventing the passage of the rays of light. Obstruction in the middle or superior meatus does not have so much and often not any influence. If the obstruction in the lower meatus is of a permanent nature the question of removal is to be considered, but temporary congestion can be removed by

the application of adrenalin, and I have found it an advantage to use it if the congestion is at all marked.

CLASSIFICATION OF CASES.

What diseases may extend to the nasal accessory sinuses and what proportion of the cases of inflammation of the nasal chambers, from whatever cause, are accompanied by involvement of the accessory sinuses, is a question of the utmost importance. I have to report the results of some work which I have done in transillumination of the accessory sinuses during the course of acute coryza. These results are, of course, subject to all the sources of error that may be encountered in transillumination in general, and the conclusions to be drawn from the findings can be accepted only subject to this element of doubt. I have transilluminated 30 cases of acute coryza, and I shall not weary you with a detailed account of each case, but rather divide them into classes or groups. This division is, to a certain extent, arbitrary, but will serve to study the condition.

Under the first group I have included all of the cases that were seen during the first twenty-four hours of the beginning of the acute coryza. There were six of these and transillumination gave negative results, although two of them later on in the course of the disease gave a shadow in one antrum. Two of them I did not see again, and in two of them the antrum and frontal sinuses remained clear.

The second class includes those cases which were seen during the later stages of the attack, or rather the cases in which the attack persisted longer than the usual cold and gave discomfort enough so that the patients sought relief from special treatment. These cases were originally more severe than the ordinary cold, or had become so by neglect or exposure. There were five of these and in two the antrum and frontal sinuses were clear, one gave a dark shadow in one antrum and one in both, and one had one frontal sinus that was dark.

The third class includes those who had pain either in the face or head. All but one of these cases had that peculiar form of headache that usually begins about 9 or 10 a. m. and continues with more or less severity for 5 or 6 hours and then disappears completely until about the same time the next day. If the pain is unrelieved it may come earlier on succeeding days and last later until it is nearly continuous. It is known under various names, such as hemicrania, brow ague, sun headache, etc. In the four cases which had this pain I found the antrum dark on the same side as the pain. I was surprised to find the frontal sinus invariably clear. I fully realize that four cases do not furnish sufficient data from which to draw conclusions, but I certainly feel that even this number of cases may stimulate others to continue the research. At present we can only say that it is interesting and, while it may be merely a coincidence, it may, on the other hand, lead to some definite knowledge of this class of headaches and in this way be of benefit to our patients. The other case was interesting from the fact that he had had a variety of diagnoses made of his disease. The pain was diffuse over the left side of the head and in the back of the neck, and he was told at first that he had beginning typhoid fever, later that he was suffering from eye strain, and after he had had his eyes examined and glasses gave no relief, that he was suffering from brain fatigue. He then consulted Dr. C. E. Meader of Lynn, Mass., who suspected the true cause of the pain and sent him to me for transillumination. I found the left antrum dark and treatment to improve the nasal drainage gave him relief from his pain, although it was several weeks before the antrum was entirely clear.

The fourth group includes the cases which had otitis media as a complication during the course of the acute coryza. There were fourteen of these and they were of the usual severity. In ten of these cases one or both antra were dark on illumination. In many of the cases the ethmoid cells were also involved, but the frontal sinus was very rarely dark on transillumination. As a matter of fact, in all of the thirty cases the frontal sinus was involved alone in only one case. I do not wish to be understood as claiming that all cases of otitis media have also involvement of the nasal accessory sinuses, but what I have found in these cases is that if the otitis media exists as a complication of acute coryza the nasal sinuses are likely to be involved. It does not seem surprising that the nasal accessory sinuses should be involved if the infection is severe enough to affect the middle ear, because the ear infection can only result from the disease extending a much longer distance than would be the case in involvement of the accessory sinuses. All of the explanations that are given for the extension of the inflammation to the middle-ear cavity apply with equal or still greater force to the extension of the disease to the nasal accessory sinuses. All cases of otitis media which did not originate as a complication of an attack of acute coryza have been excluded, and I have made no attempt to find what proportion of the cases of otitis media originate in this way. I have no theories to advance, but have confined myself to a statement of the facts which I have observed, and while it may be possible that I have had an exceptional series of cases, still I can not help feeling that, under ordinary circumstances, we shall find the nasal accessory sinuses involved in a much larger percentage of these cases than we now believe to be the case.

SUMMARY.

In closing I wish to call your attention to the following summary:

First, that to do satisfactory work it is necessary to have lamps of much greater candle power than those usually sold by instrument dealers.

Secondly, that it is rare to find the acessory sinuses dark on transillumination during the early stages of acute coryza.

Thirdly, that during the later stages of a prolonged attack it is the usual result to find one or more of them dark.

Fourthly, that hemicrania is often closely associated with antrum disease.

Fifthly, that it is almost the rule to find one or more of the nasal accessory sinuses involved when the ears are affected during acute coryza.

DISCUSSION.

Dr. Allen DeVilbiss, Toledo, Ohio—I believe my failures—to a considerable extent—in getting transillumination have been for the very reasons Dr. Cobb has stated. I shall certainly try a stronger light. His ideas of voltage are good.

Dr. B. A. Randall, Philadelphia—I wish to claim the priority in this matter for a Philadelphia man. In the Pennsylvania state medical meeting of 1885 was the first time I saw it, but Dr. Addinell Hewson had demonstrated it before that time. He then showed points that are still too much ignored. Dr. Cobb has spoken of the difficulties of darkening. Hewson made use of a small hood, something like that used in the stereoscopic apparatus or like an inverted fluoroscope, and, placing that between his own face and the patient's face, he could demonstrate everything as well in a bright room as if it were all dark. It is a convenience to remember that

a photographic dark cloth, preferably of velvet, is all that is needed to give the darkness required for this examination. These simplifications are of very great importance, because they will lead us often to make the examination when otherwise it would be passed over. One objection to the large lamps, which otherwise are strongly to be approved, is that they are inconvenient to hood. I use habitually a small lamp and, with the aural speculum, you can get transillumination of the frontal very nicely. You also can transilluminate the anterior ethmoidal cells to a large extent by throwing the light through the bridge of the nose.

The essential point that Dr. Cobb has made is that if we want to get many of our pieces of apparatus right we must go to the commercial men, who are in close competition. All kinds of batteries, with all sorts of claims not borne out in the least, and all sorts of lamps are on the market. We must have better apparatus, that will stand the fire of commercial competition. We can go to the general electric companies, if necessary, rather than to the regular instrument makers, to get pieces of apparatus that are satisfactory. One further clinical point. When I have suffered, myself, with an acute filling of the antrum of Highmore there is, ordinarily, at first no dimming of the transillumination. But on one occasion I remember being a little stuffy and greatly inclined to sniff in order to clear my head, and every time I did so I would feel the tension provoked by the rarefication of air. The sinus that was at first clear, became suddenly dark. We read of cases of polypi of the Highmore. The mucous membrane of the Highmore can puff up with edema to an inch in thickness, which is not polypoid but edematous, and this may disappear in a short time. This is due frequently to error on the part of the patient, through trying to clear the nose by sniffing, thus producing suction, rather than by blowing out the mucus. The normal delivery of the fluid secreted within is really a matter of evaporation and the moist air is carried away. In normal respiration there is sufficient exchange of air in the sinuses. I believe, to all intents and purposes, the ear is an accessory sinus in the same sense and is to be so regarded in all coryza cases. The ordinary tidal respiration produces a certain ventilation that is desirable. I know I have saved patients a good deal of discomfort and possibly more than mere temporary suffering by directing them to avoid this sniffing with its rarefication of air in the nasal chambers, when the mucous membrane was ready to take on changes quickly through vasomotor and other influences.

DR. CHARLES H. BAKER, Bay City, Mich.—This paper is a very timely one and very suggestive. In the matter of lamps there has always been great difficulty. The lamps which have been put on the market, the small lamps particularly, have been nearly always below the candle power at which they are rated. I have secured recently some lamps, smaller than the ones here, which are suitable especially for transillumination between the cheek and the jaw. They are of low voltage and they were very cheap, so that if I did burn them out they could be readily replaced. The Doctor spoke of the transillumination of the cheek and the supramaxillary fossa, but said, I believe, that he had not used it much. I believe it was at Columbus this same subject came up, and it was strongly urged that transillumination be made through the retromaxillary fossa. The following week I found a case, in which transillumination through the mouth showed no difference, apparently, but on transilluminating through the retromaxillary fossa there was considerable difference between the two sides. Following the suggestion made at that meeting, I operated through the canine fossa and I immediately got a purulent discharge, showing that the lamp had done its work satisfactorily and had enabled me to make a correct differential diagnosis. The device which I have used for operating these lamps is as follows: I have the alternating current and the alternating current controller. The usual light current received in the building is passed through a coil of moderately heavy wire, and over this is a coil of very much coarser wire, and I can regulate the current so that the voltage is lowered and the amperage increased. With this you can illuminate any lamp, from the small dental lamps to the ones here exhibited. If you have such a current, you will find that form of controller the most satisfactory. It is certainly better than any form of battery, in that it is permanent and always ready when the current is flowing. It is a great satisfaction to the surgeon to be able to demonstrate whether the sinus is involved in acute coryza, and it is important to know whether you have the sinus involved at all. In the headaches coming on periodically, say at 9 or 10 o'clock, and continuing until 3 or 4 in the afternoon and increasing in severity until perhaps an hour before they disappear, the form of the headache is almost diagnostic in itself. In a number of cases this peculiar headache has lead me to the diagnosis of the condition. The relief of the obstruction of an involved sinus has led to the cure of the headache and also to a cure of the disease.

DR. D. A. KUYK, Richmond, Va.—I would like to ask Dr. Cobb, could not the tuning fork be used as a subjective test, in addition to the transillumination? Suppose we have a heavy, dense bone, instead of a cavity, would the tuning fork reveal a difference, depending on the conduction on the affected side?

DR. C. M. COBB, Lynn, Mass.—I see no reason why the tuning fork should not be used as a method of confirming the diagnosis. I have made no claim in regard to what might be in the sinuses, as to whether they are filled with a fluid or with a swollen mucous membrane. But one point needs emphasis, and that is that all of these cases do not need operation. A much larger proportion of them will get well than in cases of acute otitis media. They recover by a process of resolution in probably nine out of ten cases and the antrum will become clear. They will always be helped by increasing the drainage. It is the rule for them to recover spontaneously.

AN UNUSUAL CASE OF NASAL SYPHILIS IN A CHILD AND A CONSIDERATION OF SYPHILITIC NASAL TUMORS (SYPHILOMATA.)*

CLEMENT F. THEISEN, M.D.

Instructor in Diseases of the Nose and Throat, Albany Medical College; Attending Laryngologist to St. Peter's and Child's Hospitals, Albany, and to the Troy Hospital.

ALBANY, N. Y.

The consideration of syphilitic affections of the nose has always been of such interest that another paper on the same subject needs no apology, even though no new ideas can be advanced. Syphilitic conditions involving the nose at times take on very unusual forms, and very often do not in the slightest degree follow the classical picture described in the text-books. This is particularly true of late tertiary lesions. Tertiary manifestations, such as broken-down gummata, destructive ulcerative processes and caries followed by the well-known deformities, are, of course, very common, and are usually easily recognized. This is not so, however, when the tertiary lesion takes the form of a tumor—a syphiloma—particularly when no history of syphilis can be obtained. This form of the disease will be the only one considered in this paper.

A considerable number of cases of tertiary nasal syphilis have come under the writer's observation, and among them there were three in which the only manifestation of the disease was the presence of tumors in the nose. In two of the cases they were attached to the septum and in one the tumor sprang from the inferior turbinate. By these tumors I do not mean the usual gummata or granulomata, which almost invariably break down if the patient does not promptly receive anti-syphilic treatment, but distinct new growths

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. Emil Mayer, C. R. Holmes and G. H. Makuen.

covered with an intact mucous membrane and not showing any tendency to ulceration. The following case demonstrates very well the fact just mentioned and the difficulties that are sometimes met in making a correct diagnosis.

CASE 1.—About a year ago a boy, aged 7 years, was brought to one of our clinics for nasal treatment. The mother, a French-Canadian, and not a very intelligent woman, gave the following history of the child's illness: During the past eight or nine months he had been breathing very badly, and this difficulty in breathing had increased very much during the past two or three months. He had lost weight and slept very badly, in fact had to almost sit up in bed during the night.

Examination.—On examination of the nose, we found both nostrils completely occluded by tumors springing from the septum, and about the size of small cherries. There were two tumors in each nostril, one of which had a distinct pedicle and looked rather like a papilloma. They were fairly firm to the touch, of slightly irregular shape, grayish in color, but covered with an intact mucous membrane, which showed absolutely no evidence of ulceration. Examination of the pharynx and larynx showed normal conditions, with the exception of slightly enlarged tonsils. He had been treated for a number of weeks in the eye and ear clinic of the hospital for a severe, right, dacryo-cystitis. Externally there was a small fistulous opening on the cheek, about an inch below the lachrymal sac, communicating with it, and discharging pus. The boy was very anemic and had a severe reflex asthma. Examination of the urine and sputum gave negative results. After carefully questioning the mother we discovered that her husband had died of tuberculosis, and that she had lost a sister by the same disease, but we could at this time obtain no history of syphilis. It was positively denied.

Treatment.—The boy was given Fowler's solution, and treated locally for a time, because the mother objected to operative procedures. His condition finally became so pitiable and the asthma increased to such an extent, that we were allowed to operate. Under ether, both nostrils were thoroughly cleaned out. Careful examination with the probe during the operation failed to reveal the presence of caries. He improved very much for a time, but within two months both nostrils were again completely obstructed. The mother then finally admitted that her husband had acquired syphilis, and that she had been infected before the birth of this child. There being now no doubt of the diagnosis, the boy was given potassium iodid and began to improve at once. Within two months he was practically well, the nasal tumors and the asthma having entirely disappeared. We saw him from time to time during the next six months, and both nostrils remained entirely free.

Histologic Examination.—Portions of the removed growths showed that the tissue was made up of round cells, with here and there cells similar to spindle cells. There was also a connective tissue formation, and thickening of the walls of the blood vessels. Tubercle bacilli and tubercles were not present. This examination, with the result of the treatment, made the diagnosis of syphiloma positive.

The case, I think, presents some very unusual features. Here was a boy with congenital syphilis—the only indication of the disease being the presence of the nasal tumors—who had never before received anti-syphilitic treatment, and nevertheless the nasal growths at the time he was examined showed no evidence of breaking down. This one fact, without the histologic examination, is enough to prove that they were neither gummata nor tuberculous granulomata. Another interesting point is the distinct pedicle that one of the tumors had and the presence of the syphilomata in both nostrils. In most of the cases of nasal syphiloma the tumors are confined to one nostril. One of Frank's cases was also an exception to this rule. I would very briefly like to refer to two other cases, observed during the past few years:

CASE 2.—Mr. G. S., aged 36, married and the father of healthy children, consulted the writer in May, 1897, for what he thought was a "cold in the head." His family history was excellent, there having been no cases of either tuberculosis or syphilis. The patient had had a chancre some years before I saw him, but had not had any other symptoms of syphilis.

Examination.—The sputum and lungs were negative. The posterior nares, pharynx and larynx showed normal conditions. A growth the size of a walnut, firm to the touch and showing no evidence of breaking down, was present in the right nostril, and was attached to the septum.

Treatment.—This was removed with a snare, and the seat of attachment thoroughly cauterized. Recurrence after three months. The patient was then put on iodid of potash, and recovered completely, the tumor entirely disappearing and not recurring.

Histologic Examination.—As in the last case there was a connective tissue formation and thickening of the walls of the blood vessels, but a considerable number of tubercle bacilli and giant cells were also present.

An examination of the patient's nose four years afterward showed that both nostrils were in a normal condition. There was no indication in the right nostril of a return of the growth, and examination of his nasopharynx, larynx, pharynx and lungs was also negative.

In this case the histologic findings, with the exception of the endarteritis, would speak rather more for a tuberculoma than for a syphiloma. The absence of any ulceration, however, and the rapid disappearance of the tumor when iodid of potash was administered make the diagnosis of a syphiloma positive, I think. Giant cells as shown by a number of writers (Kuttner, Browics, Manasse) are sometimes present in syphilitic tumors. The presence of tubercle bacilli in this tumor is of considerable interest, because it has been claimed that they are never found in syphilomata. Tubercles with cheesy centers were not found.

CASE 3.—The last case of my own, which I wish briefly to mention, is that of a man, aged 58, who consulted me March 1, 1901, for nasal obstruction. For several months he had not been able to breath at all through the right nostril, and he had suffered a great deal from headache. I had removed polypi from his nose several times, and thought, of course, that he was suffering from a recurrence of the same condition.

Examination.—On examining the nose, however, I discovered a large tumor completely filling the right nostril, and apparently springing from the inferior turbinate. It had an irregular surface, was firm to the touch, and had an intact mucous membrane, with the exception of two or three small superficial erosions, but there was no evidence of any breaking down. The glands on the same side of the neck were somewhat enlarged, and the right cheek in the region of the antrum was very hard and much swollen. I told the patient that I could not make a positive diagnosis without removing a piece of the growth for examination. I really thought, however, from the appearance of the growth and the patient's age, that it was probably a sarcoma, having its origin in the antrum of Highmore. Most of the tumor was removed with the hot loop and examined by Dr. George Blummer of the Bender Laboratory, who reported that it was not malignant, but that it was a granuloma and probably a syphiloma. The histologic findings were the same as in the first case reported. The patient now admitted that he had had a chancre five years before.

Treatment.—He was given iodid of potash, and what was left of the tumor rapidly disappeared, every trace of it subsiding within six weeks. There has been no recurrence since that time.

Syphilitic nasal tumors of this kind are certainly of a distinct and unusual type, and belong in a class by themselves. The term syphiloma, first given to these tumors by Wagner, although objected to by no less an authority than Virchow,[18] is, I think, a good one, because, as will be brought out in the differential diag-

nosis, they are not exactly the same as syphilitic granulomata, and they are certainly not gummata. Kuttner,[15] in his able article on nasal syphiloma, has reported four cases of this kind, of which I will give brief abstracts.

Case 4.—Woman, aged 33; no history of syphilis. In the right nostril grayish-red tumor masses, attached to the middle turbinate. On microscopic examination, walls of the vessels were found thickened. Recurrence after removal. Anti-syphilitic treatment and cure. No recurrence after nine months.

Case 5.—Woman, aged 42; no history of syphilis. Large tumor in right nostril attached to septum. Microscopic examination of removed portion negative. Recurrence after removal. Anti-syphilitic treatment followed by cure. No recurrence after six months. Giant cells were present in large numbers.

Case 6.—Woman, aged 31, who some years before had been infected with syphilis. Small tumor attached to inferior turbinate, right nostril. Microscopic examination showed presence of giant cells and thickening of vessel walls.

Case 7.—Woman, aged 28. Right nostril filled with hard, red tumor masses attached to septum. No history of syphilis. Microscopic examination the same as in the other cases.

Ripault[12] has also reported a case. Manasse[7] has reported five cases of the same nature from Kuhn's clinic, based on careful microscopic examinations. In his cases the tumors also had smooth surfaces and seldom showed any indication of ulceration. According to his conclusions they may occur singly or they may be multiple, and are usually attached to the septum. Their color is grayish red. They may be attached by a pedicle or may have a broad base. They were composed of granulation tissue and round cells, which were separated by very little intercellular substance. In a number he found giant cells, but never real tubercles with cheesy centers nor tubercle bacilli. He considered them connective tissue tumors arising from the submucous connective tissue, and very similar to tuberculomata, from which they differ by the absence of tubercles with cheesy centers and bacilli. Thickening of the arterial walls speaks for lues, but Chiari[17] has found this in nasal tuberculomata. Three cases have been reported from Kuhn's clinic by Frank.[4] The tumors in these cases were at first thought to be sarcomata. They disappeared after iodid of potash was given. In two of the cases the tumors were attached to the septum, in the third case, a child 12 years old, both nostrils were filled with hard tumors. A case has been reported by Krecke[11] in which two granulation tumors, the size of pigeon eggs, were present, one on the posterior wall of the pharynx and one in the nose. Scheinmann[13] describes cases in which he speaks of a syphilitic thickening of the turbinates. This particular type of tumor (syphiloma) is not mentioned at all in many of the well-known monographs and text-books on the nose and throat.

THE DIAGNOSIS.

In considering the differential diagnosis we find that these tumors may be mainly confounded with tuberculosis granulomata, simple granulomata, inflammatory fibromata, lupus nodules, gummata and malignant neoplasms. First it must be remembered that no one of the symptoms that patients with nasal syphiloma complain of, the pain in the head, face and arm, is absolutely characteristic. The same symptoms are present in other affections of the nose, i. e., tuberculosis, caries and malignant tumors (Kuttner). There are several points which macroscopically distinguish these tumors from tuberculomata. They are usually of a peculiar grayish or grayish-red color, firm to the touch and are at times covered with a tenacious, fibrinous exudate. There are sometimes small erosions on the surface of the tumors, but very rarely much ulceration and they do not break down easily. Manasse observed a deep ulceration in one of his cases. In cases of true syphiloma there is very rarely caries present, and it is doubtful whether a number of the cases on record (the first, fourth and fifth reported by Manasse, and Kuttner's fourth case), in which the syphilitic tumors had their seat in close proximity to septal perforations, belong in this class. Septal perforations occurring during the course of syphilitic affections are undoubtedly the result of gummata breaking down and involving the periosteum. The inflammation of the surrounding tissues accompanying this destructive process may be the cause of some of these granulation tumors arising near the perforation. In the writer's three cases no evidence of caries could be found. The tuberculoma almost invariably has its seat on the anterior part of the septum, although there are a few exceptions, as in one of Kuttner's cases, in which the tumor was attached to the middle turbinate, two of Störk's and one of Chiari's. They show a much greater tendency to break down and usually have either superficial or deep ulcerations. Histologically the diagnosis may be almost always positively made. Goerke[8] claims that the finding of tubercle bacilli in these tumors is a positive differential diagnostic sign. That this is not always true is proved by the writer's second case, in which tubercle bacilli were found in an unquestioned syphiloma. The vegetative form of nasal tuberculosis described by Gourdiat,[6] which simulates a malignant neoplasm, must also be considered. These growths also have their seat on the septum and are of slow development. The diagnosis can usually only be made by the histologic examination.

The syphiloma microscopically is made up of round cells and between them some spindle cells. There is also a formation of connective tissue. Walls of the blood vessels are thickened. There are never real tubercles with cheesy centers and very rarely tubercle bacilli, as in the tuberculoma. It must be borne in mind, however, that Chiari has found thickening of the vessel walls in tuberculomata, and that simple granulomata, which also have their seat on the septum, sometimes contain giant cells and thickening of the walls of the vessels. Baumgarten was the first to point out the fact that giant cells are present in gummata, and they were also found by Manasse, Browics,[1] Brodowski[2] and others. Kuttner and Manasse have also found giant cells in typical syphilomata. So that histologically the structure of syphilomata and tuberculomata is very nearly the same, really the only points of difference being the presence of tubercle bacilli and tubercles in tuberculomata. Tubercles with cheesy centers, so far as I could discover, have not been found in a syphiloma, and when found would make the diagnosis of a tuberculous tumor positive. Thickening of the vessel walls, as a rule, speaks for a syphilitic tumor. After all, then, when all is said, the administration of iodid of potash is one of our greatest diagnostic measures.

The diagnosis of a simple granuloma has been sufficiently considered. It differs not only in appearance, but in its histologic structure. That of fibroma and lupus can usually also be made microscopically. The differential diagnosis of a syphiloma from a malignant neoplasm, and particularly from a sarcoma, often presents difficulties which are not always cleared up by the microscopic examination. It is sometimes very difficult, as shown by Finder,[14] to distinguish a granulation tumor from a small, round-celled sarcoma. This has been well brought out in a case reported by Levy,[10]

in which a small tumor was present in the region of the middle turbinate. A portion was removed and examined by two competent pathologists, and both agreed that it was a small, round-celled sarcoma. The growth entirely disappeared when iodid of potash was administered. The tumors in Frank's cases were also at first considered to be sarcomata. The diagnosis of a malignant growth in the nose can, however, as a rule, be easily made by the subsequent history of the case, by the microscopic examination and by exclusion. The diagnosis of gummata has already been partially considered. Macroscopically they differ from syphilomata in that they are much less elevated above the surrounding mucous membrane and break down very readily. They resemble the syphiloma more nearly than any other tumor. Histologically they are made up almost entirely of granulation tissue (Langenbeck[9]).

In conclusion, a statement made by John N. Mackenzie[3] some years ago should always be remembered. In considering late forms of congenital syphilis he said, "that it may lie in a quiescent state in the system for many years after birth, and when it does make its appearance the outbreak usually occurs in the pharynx and in the form of deep destructive ulceration."

So that when a tumor such as I have attempted to describe in this paper (and I realize but poorly and insufficiently), is found in the nose, especially of a young person, and if it resists the ordinary methods of treatment and promptly returns after removal, this unusual form of syphilis should be thought of.

DISCUSSION.

DR. W. S. ANDERSON, Detroit—This paper has been very interesting to me, because I have had an opportunity to study a number of such cases. A young girl, about 15 years of age, came to my clinic with an obstruction in the right nostril of three or four months' duration. I found a small growth on the cartilaginous portion of the septum, and back of that was another tumor. The nasopharynx was filled with the growth. There was a large infiltration of the lymphatic glands under the jaw. There was no history of syphilis in the family, so at that time the diagnosis, to my mind, was either sarcoma or gumma. There were many points in favor of each diagnosis. There was no pain and only in the nasopharynx did the growth appear to be of a malignant nature. I put the child on inunctions and iodid of potassium, and the growth gradually disappeared, until at the end of three months there was not a vestige left. The patient completely recovered. There are several points I would like to make. First, we can not depend very much on the history. Very often we find syphilis where we can get no history whatever. Second, we should not be in haste to operate until we have excluded syphilis. It would be much better to put these patients on a course of antisyphilitic treatment before operating. Third, mercury is of distinct service, and we should not depend on iodid of potassium alone. There is nothing so satisfactory as mercury by inunction, together with iodid of potassium. In my experience, and I believe it is true in the experience of others, these cases occur very often about the age of puberty, and they seem to be more common in females than in males. Why, I do not know. In some cases I have been able to find diagnostic signs that would indicate that early in life they had had syphilitic manifestations. For instance, in one case there was an iritis, and in another affection of the pharynx and Hutchinson's teeth. In the majority of cases the syphilitic manifestations are so light as to have been passed unnoticed. I have under observation at present a man who has a swelling over the ethmoidal region, pressing the nose out, with a distinct history of syphilis 25 years ago. The diagnosis of syphilis was made by the attending physician, but he said he had him under antisyphilitic treatment without result. It appeared to be either syphilis or sarcoma. It disappeared under antisyphilitic treatment. It seems to me we should not place too much stress either on the lack of a history of syphilis, or on the statement of the family physician that he has given antisyphilitic treatment. If we put these cases on thorough courses of mercury and iodid of potassium we will often secure excellent results. This is just as true in other parts of the body as in the nose. We should give the patient a chance by antisyphilitic treatment before operating.

DR. WILLIAM L. BALLENGER, Chicago—I wish to suggest that perhaps one of the diagnostic points is not so reliable as stated by the essayist and by the last speaker. Is it not true that antisyphilitic treatment will reduce other growths than those due to syphilis? My impression is that it will in some instances. If that is true, it is not of so much importance as a means of differential diagnosis.

QUESTION—What kind of growths?

DR. BALLENGER—Sarcomata, tubercular growths, and I am not sure but carcinomata.

DR. J. C. BECK, Chicago—The paper interested me very much from the pathologic point of view, in regard to finding tubercle bacilli in specific growths. I have in mind a case of ablation of the nose from specific involvement, where what appeared like the tubercles of tuberculosis were excised and examined microscopically, we found the tubercle bacilli. These were absolutely proven to be tubercle bacilli by culture. The case was demostrated by Klebs, who for a short time resided in the United States, and it was proven to be a tubercular growth and beside a distinct syphilitic lesion. The child recovered absolutely under antisyphilitic treatment. Fraenkel, as well as many other authors, has found several times mixed infection of this nature, so that these double infections do occur. The disappearance of the growth, after the positive diagnosis was made, and the non-recurrence of the growth, are interesting. A distinct carcinoma of the larynx was shown by Dr. Head of Chicago, in which the diagnosis was confined by microscopic examination. The administration of large doses of iodid of potassium reduced the tumor to half the size for two months, when the case went on in the usual course of carcinoma. Sarcoma does not involve the glands, as a rule, so that when the glands are involved that condition would not come in for consideration. The involvement of the glands would speak rather for syphilis. Iodid of potassium does reduce infiltration, transudations and exudations, whether they are of specific or malignant nature.

DR. D. A. KUYK, Richmond, Va.—I wish to report a case of inherited syphilitic rhinitis in an infant, 11 months old,

referred because adenoids were suspected. Instead, the mucous lining of inferior turbinates was enormously enlarged, almost protruding from the nares. The cartilaginous portion of the nose was much enlarged, looking blue, due to venous stasis. Emaciation was very marked. Family history was unsatisfactory, but from mother's personal history and infant's appearance inherited syphilis was diagnosed. Inunctions of blue ointment were freely used and flexible collodion applied externally to the swollen cartilaginous extremity. In two months the growth had reduced so that there was some nasal breathing. In another month improvement in every respect was very marked, and I have since learned that the child is practically well, though still continuing at intervals to use the antisyphilitic treatment. The diagnosis in this case, though no history was obtainable, was undoubtedly confirmed by the result of the treatment.

DR. PETER J. GIBBONS, Syracuse, N. Y.—It is true that iodid of potassium will reduce many tumors, as well as syphilitic enlargements. But be sure that the iodid is a preparation that you can rely on. Be sure that it is pure and run up the dose to tolerance. As the essayist said, you often find not only general practitioners but members of our branch giving iodid of potassium in gr. vi-xv-xx and not getting desired results. It is hardly necessary to call attention to this at this time, but you must get the dose up to tolerance, which may be anywhere from gr. ii to gr. c., three, four or five times a day. But be sure that your iodid of potassium is iodid of potassium and not sawdust, pipe clay, or some other substitute. If the case is cured by iodid of potassium, we might safely say that it is syphilis, although we, no doubt, get relief in other tumors.

DR. EDWIN PYNCHON, Chicago—Dr. Baldwin of Chicago assures me that he has given iodid of potassium in doses as high as 800 grains a day, and thus gets much better results, that we ordinarily would fail to get with the usual maximum dose.

DR. CLEMENT THEISEN, Albany, N. Y.—Dr. Anderson spoke of cases in which the ethmoidal cells were involved. I tried to differentiate between the syphilitic granuloma and the conditions present with inflammatory processes. In regard to Dr. Anderson's statement that antisyphilitic treatment should be tried before operative treatment, I agree with him, whether there is a history of it having been tried before or not. But in the cases I mentioned it had not been used before. I have, myself, had much better results from iodid of potassium alone than from the combined use of the iodids and mercury in tertiary lesions. Iodid of potassium certainly does influence other growths, as has been said. But in the one case I mentioned, there has been no return for four years, and in the other case there has been no return now for a year and a half.

PERFORATION OF THE NORMAL INTESTINE BY AN ASCARIS LUMBRICOIDES.*

LOUIS C. AGER, M.D.
BROOKLYN, N. Y.

NARRATION OF A CASE.

History.—The patient was American born, 36 years old, a carpenter. On Sept. 24, 1901, about 9 a. m., he walked into the Norwegian Hospital, Brooklyn, complaining of diffuse abdominal pain; temperature, 99; pulse, 90. He gave a history of diarrhea for a week, which had been checked by cholera mixture. The previous night he had taken a dose of castor oil.

He was kept under observation, and rapidly grew worse. At 11 o'clock his temperature was 102; pulse, 120. The abdominal pain was localized in the right iliac fossa, and a diagnosis of appendicitis was made. An operation was decided on. At 12:15 p. m. his temperature was 104, pulse 136.

Operation.—At 4 p. m. the abdomen was opened and a congested appendix was removed. Although there were indications of intestinal perforation, the alarming condition of the patient prevented any search. The operation was completed hurriedly; pulse 167.

The patient died at 4 a. m. the next day, and an autopsy was made at 10:30 a. m.

Autopsy.—On opening the abdomen a large amount of mucopurulent fluid gushed out. There was an acute exudative peritonitis most marked in the right lower quadrant. The intestines were matted together with an exudate, in some places a quarter of an inch thick. On separating the coils of intestines a living lumbricoid was found. After a short search a small round perforation was found in the small intestine, about ten inches above the caput coli. On opening the intestine no other lumbricoid was discovered, and the mucous membrane seemed, except for the clean-cut perforation, entirely normal.

CASES AND OPINIONS IN THE LITERATURE.

On looking up the history of this subject I find various opinions recorded. Many authors are of the opinion that the ascaris is utterly incapable of puncturing the intestinal wall, while others after reviewing the evidence are convinced that the accident does happen at times. In fact, those who deny the possibility do so on entirely theoretical grounds, while those who admit it do so only after a careful study of facts. In Meigs & Pepper's "Diseases of Children," edition of 1870, p. 875, is the following:

> Among those who advocate the possibility of perforation independent of previous change in the intestinal coats by disease are M.M. Mondiere and Charaday, the former of whom has examined the subject with a great deal of care. . . . Rilliet and Barthez and M. Guersant. . . .
>
> We confess ourselves inclined to believe . . . that worms may in some instances cause a perforation independently of previous disease of the coats of the intestine.

Leuckart, in his "Parasites of Man," p. 138, says:

> The possibility of such perforations has been much questioned. . . . It has been attempted to explain these cases . . . by the supposition that the worms play only a secondary part. . . . I think the denial of these perforations is quite unfounded. . . . In some cases the boring is not confined to the wall of the intestines.

T. S. Cobbold, in his book on "Parasites," London, 1873, takes the same view and cites eleven cases, some evidently due to slow erosion, others apparently direct perforations.

In the "American Text-book of Pathology," p. 341, is the statement in regard to ascaris, "It may perforate the alimentary canal." Dr. Stengel, in his "Text-book on Pathology," expresses the opinion that previous intestinal ulceration is an important factor in these cases.

Dr. Flint, in his "Practice of Medicine," edition of 1886, p. 560, says: "It is not probable that the worms ever perforate the intestines as was formerly supposed."

C. Davaine, in his article on "Lumbricoides" in the "Dictionnairre Encyclopedique des Sciences Medical," analyzes 47 cases and expresses the opinion that such puncture can not take place.

AUTHOR'S THEORY OF THE CASE REPORTED.

My own theory, after a careful study of this specimen in a fresh state, is that the worm became blocked in a transverse position in the intestinal canal with one end caught by a fold or irregularity of the mucous membrane, and that partly by its own movements and partly by peristalsis it was slowly forced through the intestinal wall. This process may have been going on during the whole week that the patient was having intestinal disturbances, the peritonitis coming on suddenly as soon as the worm passed completely into the abdominal cavity, permitting the escape of the intestinal contents.

DISCUSSION.

DR. HENRY B. WARD, Lincoln, Neb.—I know of a number of cases in which the worm was found to have penetrated a diseased bowel, but I believe only one case has been reported in which a positively normal gut has been penetrated by this parasite. I can hardly understand how the worm can become blocked in the intestine and gather sufficient force to push itself through the normal wall. The ascaris has a firm body, and can not coil itself closely, as the body breaks when bent. Usually the head of the male worm is more pointed than that of the female, and the worm in this specimen is evidently a male.

DR. W. A. EVANS, Chicago—This worm has been found frequently in the lower animals, imbedded in the wall of the intestine below the mucous membrane, but rarely ever penetrating the muscular coat. This is seen especially in hogs.

DR. HENRY B. WARD, Lincoln, Neb.—I have known the wall of the intestine to be penetrated by certain other worms, as the ankylostoma or uncinaria and trichocephalus, but it is exceedingly rare for the ascaris to penetrate the mucous membrane.

DR. LOUIS C. AGER, Brooklyn—There are cases reported in which large numbers of these worms have gotten into a mass and, by erosion, produced ulceration. There are also cases of umbilical abscess reported, in which the worm has been discharged from the umbilicus, probably due to a patency of the fetal duct leading to the umbilicus. No histologic examination of the gut was made in this case, but the macroscopic appearance gave no indication of chronic ulceration. Moreover, it would be a strange coincidence if a single small ulcer had existed in the gut and that this worm should have found that spot. I think this worm must have worked its way through the bowel by a slow process of erosion of the tissues. There have been cases reported in which lumbricoides have been found in the kidney, inguinal glands, and other places adjacent to the intestinal tract, and they have even been discharged from the eye duct and from the auditory canal. I do not believe that this worm braced itself transversely, but more obliquely, in pushing its way through the bowel. The lumbricoid can coil itself to a limited extent. I have seen one case in which 50 or 60 worms were in one mass, all being coiled on themselves and on each other. One case has been reported in which 5,000 worms were discharged in the course of 18 months.

Typhoid Fever at Lille, France.—Professor Lemoine, in discussing the marked and permanent increase in the number of cases of typhoid fever at Lille, remarks that the majority occur among the well-to-do, and in the fall. Most of the patients had spent the summer elsewhere, and had thus lost their relative immunity to the local water, while the early fall rains pollute the water more or less. The extensive work on the streets has brought to the surface long buried generations of microbes which are whirled about in the dust and fill the hospitals during the dusty season. The only time when the hospitals are comparatively empty is during wet, foggy weather when the microbes are held down by the moisture under foot. But this is the time when the typhoid germ is most active, as it reaches the system in the drinking water. His article appeared editorially in the *Nord. Med.*, Dec. 15, 1902.

THE CLINICAL APPLICATION OF SOME THYROID GLAND EXPERIMENTS.*

L. BREISACHER, M.D.
Consulting Gastroenterologist, Harper Hospital; Formerly Professor of Comparative Physiology, University of Pennsylvania; Member of American Physiological Society.
DETROIT.

In 1890, at a time when little or nothing was known of the chemical constitution of the thyroid gland and when we were unaware that it possessed any particular therapeutic action, the writer offered the first experimental proof that the thyroid gland was in some manner concerned in the general metabolism of the organism.[1] While even to-day we are not in possession of any positive proof of the true physiologic rôle of the thyroid gland, its action as a therapeutic agent, and further the clinical and experimental results following total extirpation along with the action of diet in various thyroid diseases and after total extirpation of this gland, indicates that it is in some manner invested with a metabolic function, but which we are not as yet able to particularly define. It would lead us too far were I to attempt to give a résumé of the various phases through which the subject of the function of the thyroid gland has passed. For the reason, however, that both Victor Horsley[2] and F. Blum[3] have misconstrued my position in reference to the metabolic significance of the thyroid gland to the organism, I should like, in a few words, to explain the circumstance which prompted me to study the influence of diet on thyroidless animals.

In 1888, when I first took up this subject, Professor Munk, in whose laboratory I was pursuing my work, believed that the thyroid gland could not be looked on as being of absolute vital significance to the organism, for the reason that some animals remain perfectly normal after total extirpation of this gland, and as late as 1897 Professor Munk[4] again emphasized this statement. He believed that the symptoms following the total extirpation of the thyroid gland were in a large measure the result of irritation of the vagosympathetic nerves and their branches.

The writer instituted a series of experiments in which he applied both chemical and electrical irritation to the various cervical nerves without, however, producing in any case symptoms resembling those noticed in thyroidless animals. To definitely decide this question the writer devised the following method of experimentation: First, the left vagosympathetic and the superior laryngeal nerves were extirpated, the superior incision being made at the superior ganglion and the lower incision half an inch below the lower border of the thyroid gland. The animals were carefully observed during a period of three weeks following the operation; they remained perfectly normal. Following this period the right thyroid gland was totally extirpated and the animals again carefully watched for a period of three weeks, during which time they remained in an absolutely normal condition. Finally the thyroid lobe on the side on which the vagosympathetic had previously been removed was extirpated, and it was shown that the dogs succumbed in precisely the same manner as did the dogs in whom this method had not been resorted to, thus proving that nerve irritation is not absolutely necessary to the production of death after total extirpation of the thyroid gland. Professor Munk, and also E. Fuhr,[5] had noticed that the first thyroid symptoms, fibrillar, clonic and tonic muscu-

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. Alfred Stengel, L. Hektoen and Winfield S. Hall.

lar contractions with cardiac and respiratory distress, following total thyroid gland extirpation often were developed after the feeding of meat. They ascribed this circumstance to the mechanical irritation which the meat produced during its passage into the stomach.

The negative results of the experiments which I have just detailed in reference to nerve irritation, etc., in connection with several observations I had made in feeding boiled meat, led me to institute the experiments on the influence of the feeding of milk and eggs and raw and boiled meat on thyroidless animals.

These experiments consisted in keeping dogs on a diet of milk or milk and eggs for a number of days and then performing a total extirpation of the thyroid gland, or a partial extirpation and then finally a total extirpation and thereon noting the influence of a milk, egg, boiled and raw meat and beef-broth diet. It was shown that 30 per cent. of all animals fed on a milk or boiled meat diet, but particularly a milk diet, remained entirely healthy, but died when put on a raw-meat or beef-broth diet. All of my animals that were fed on raw meat from the beginning of the experiment succumbed to the operation.

These experiments then furnished the first evidence of the metabolic significance of the thyroid gland to the organism, and further, that a milk diet acts more favorably than a raw-meat diet in dogs in whom a total thyroid gland extirpation has been performed.

Following the publications of these results, De Quervain,[6] Rosenblatt,[7] Glinatz,[8] Glunzinki,[8] Lanz[9] and Blum[3] repeated my experiments and corroborated the conclusions I had reached, viz., that a milk diet acts more favorably than a meat diet after total extirpation of the thyroid gland.

Clinically the results of these experiments have been found to be of considerable importance. Thus, Nothnagel, in his chapter on myxedema, recommends the withdrawal of meat and the substitution of a milk and vegetable diet in the treatment of this disease. Rumpf, v. Ziemssen and Blum likewise recommend the same course of dietary in the treatment of thyroidal diseases. Professor Ewald, in his work on the thyroid gland, also states that the clinical application of the milk-feeding experiments is of great value in the treatment of various thyroidal conditions. He remarks:[10] The best results are achieved in the treatment of myxedema and cachexia strumipriva where a milk and vegetable diet is persisted in. Both Strich and Lanz independently came to the same conclusion.

Lastly, Moebius[11] recommends the same course of dietary in the treatment of Basedow's disease. I have been prompted to give a short sketch of these experiments and their clinical application for the reason that while most clinicians on the other side of the water lay considerable stress on diet in the treatment of thyroidal disease, American clinicians have paid little or no attention to the subject.

THE CHEST-PANTOGRAPH.

ITS PHYSIOLOGIC SIGNIFICANCE AND ITS CLINICAL APPLICATION.*

WINFIELD S. HALL, Ph.D., M.D.
Professor of Physiology, Northwestern University Medical School.
CHICAGO.

Not long ago a prominent clinician of Chicago requested the writer to contrive an apparatus by which chest contours could be accurately measured and recorded. Such an instrument was said to be needed by those who specialize in diseases of the thorax or who have any occasion to record thoracic conditions for statistical or other purposes.

The writer's first attempt to solve the problem given him by the clinician was a rather expensive experiment, with an instrument which consisted of about twelve curved lever arms, which came down to the thoracic walls, touching its circumference at any desired plane. The short arm of these levers was provided with a needle which pricked in a paper a line of holes which represented the chest contour. This was found to be a faulty apparatus in several important points, and it was discarded.

One day the writer saw an artist making charts for lecture room use, by enlarging figures from a book, the

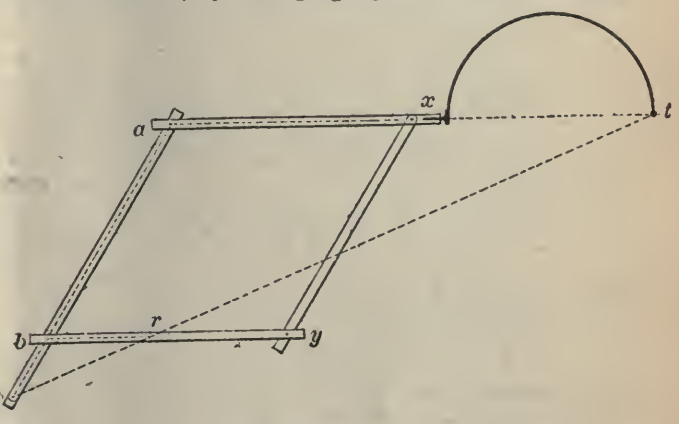

Figure 1.

outline of the figure being traced with a pantograph. The idea of reversing the process and making a reduced outline of the chest was adopted, and the first apparatus made was a success.

Figure 1 shows the instrument, which is constructed of brass or wood, with brass or steel semicircle. The joints, *a, b, x* and *y,* move easily in the plane of the instrument. The semicircle, 40 inches in diameter, rotates at *x* around the diameter *tx*. The point *f* is fixed to a table. With *f* a fixed point, all movements of *t,* the tracing point, are accompanied by corresponding movements of *r,* the recording point. The triangles *frb* and *fta* are similar triangles in all positions of the instrument. If these two triangles are similar, their corresponding sides must be proportional, therefore, *fb:fa::fr:ft;* but *fb:fa::1:5,* therefore, the distance *fr* is always one-fifth the distance *ft*. In other words, the recording point, *r,* which is represented in the instrument by a pencil which records its movements on ruled paper, is always one-fifth as far from the fixed point, *f,* as is the tracing point, *t*. This recording point, *r,* moves in the same direction as the tracing point, *t,* the only difference being that it moves only one-fifth of

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. Alfred Stengel, L. Hektoen and Frank B. Wynn.

the distance through which *t* moves. This results in the formation on the paper of a contour tracing of the thorax, absolutely accurate in every curve and diameter, except that it is reduced to exactly one-fifth the actual dimensions.

The object of the semicircular arm is, of course, to permit the tracing point, *t*, to be carried around the thorax. The seat on which the subject sits may be adjustable in height, or the table on which the instrument is fastened may be adjustable in height; in fact, it has been found that there is advantage in having both an adjustable table and an adjustable seat. If one wishes to take contours at various levels of the body between the shoulders and the pelvis, there should be a back rest to keep the subject's body from swaying backward and forward or from side to side. This back rest can take the form of a simple rod about one foot in length, inserted into the edge of the table. This rod should extend out horizontally and at right angles with the edge of the table, and should be located opposite the point in the table where the pantograph socket is fastened to the top of the table.

With all these conditions satisfied (and they are not difficult conditions), let the subject to be examined sit beside the table, with table and seat so adjusted as to bring the plane of the thorax to be examined into the plane of the instrument, that is, on a level with the top of the table. Place a sheet of the record paper on the table parallel with the sides of the table and held in place with thumb tacks. Let the subject inflate the lungs, place the tracing point, *t*, on the distal side of the thorax at a point marked on the skin; sweep the tracing point around the posterior aspect of the thorax to a point on the proximal side; rotate the semicircle so that its convex side will be anterior; sweep the point, *t*, around to the starting point. You have now traced a contour at the end of inspiration. Let the subject exhale to the position of repose, or, if desired, to the position of forced expiration. Then retrace in the opposite direction, and the result will be such as shown in Figure 2. This tracing has the advantage of showing the general type of the thorax, and the relative diameters in any direction. It shows the amount of expansion, and, furthermore, it shows whether or not this expansion is symmetrical.

The accompanying figure shows two such contours from healthy, well-developed men. Two millimeters in the figure equal one centimeter of actual measurement. The inner contour is that of forced expiration, while the outer one is that of forced inspiration. In contour A the increase of lateral diameter by forced inspiration is 2 cm., while the increase of dorsoventral is 3 cm. In the same contour the cross sectional area of the thorax in the plane of the ninth rib is represented by 25.52 of the larger squares containing 25 square cm.; total area equals 637.5 square cm., while the cross sectional area of the chest in forced expiration is 517.5 square cm. Forced inspiration shows an increase of 120 square cm., or about 23 per cent. over cross sectional area of forced expiration. Furthermore, both contours show a prominence in the right side (left of the figure) possibly due to stronger musculature on that side.

The instrument accomplishes the purpose for which it was intended, and seems to be well adapted for use in all cases where chest contours are desired for either clinical or statistical purposes.

Any abnormalities in contour, even slight though they may be, are instantly made apparent in the outline, when an inspection would not reveal them and measurements of diameters would do so only after a laborious comparison of results with tables of average and typical measurements.

The general character of the chest, whether flat or deep or normal, is also made apparent to both observer and subject, and the record is an important part of the data which indicate a line of exercise to develop those dimensions which are below grade or to diminish dimensions which may be abnormally large. One's thought turns in this latter instance to cases of "pigeon-breast" in boys, cases which, even in mild degrees, are made strikingly apparent in the contour, and cases in which the influence of proper exercise in early youth may be wholly corrective or decidedly ameliorative.

The insurance examiner, the physical examiner of the Y. M. C. A. or of the college gymnasium, the physical examiner for the army and navy, as well as the specialist in chest diseases, will at once see the utility of having these records of chest contours.

In closing, the writer wishes to call attention to some of the advantages of this instrument over other instruments which are intended to accomplish a similar purpose:

1. The chest pantograph is so simple in construction that it does not easily get out of adjustment and can not readily be injured in use.

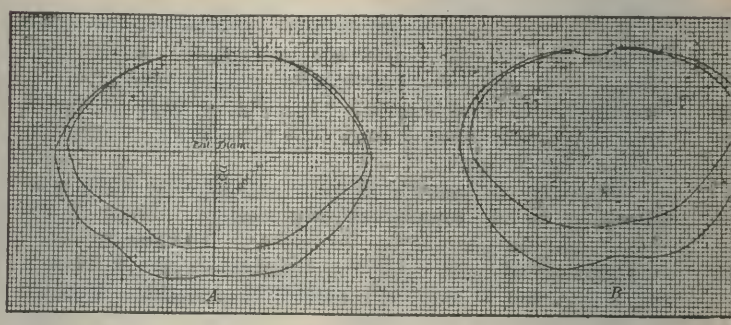

Figure 2.

2. It is inexpensive.

3. It is compact; when not in use it can be folded back along the back of an office table or lifted from the table socket and hung on the wall.

4. The record is accurate, and is reduced in size to dimensions readily adapted to filing away with clinical records.

5. The record being a graphic one appeals at once to the eye and reveals all divergencies of the contour from the normal without the necessity of reference to tables of averages.

An Unheeded Peril in Preserved Meats.—Giovanni Grixoni has found that the fluidification of the gelatin contained in cans of meat, and in bottles of concentrated broth is a very certain sign of damage, even when other signs are lacking. This fluidification is due to the action of living bacteria and trypsinic ferments secreted by them. Peptonized preserved meats have toxic powers, for, whether inoculated into, or eaten by rats and mice, they cause their death. The toxins produced in fluidified preserved meats have a powerful antibacterial action, prevent the development of putrefaction, and are soluble in water. They are destroyed by a temperature of 100 C. Serum diagnosis in infections of alimentary origin is an excellent method for the recognition of the etiological agent. The prolonged presence of microbes in the can profoundly modifies their biological properties, prevents their development, and finally causes their death. Cans containing living germs, even if these are saprophytic, should be excluded from the dietary. —*La Rif. Med.*

NERVE NOSTRUMS AND THEIR DANGERS.*

WILLIAM P. SPRATLING, M.D.

Medical Superintendent of the Craig Colony for Epileptics, Secretary of the National Association for the Study of Epilepsy and the Care and Treatment of Epileptics.

SONYEA, N. Y.

Nerve nostrums and their dangers constitute a subject far too comprehensive for full discussion in the brief time at our disposal, and we will omit the presentations of facts that aim to show what a race of nostrum makers and nostrum takers the American people are coming to be, and take up other matters connected with the subject that should engage our undivided attention, and which are as follows:

1. Why do people take nerve nostrums; or, indeed, nostrums of any kind?

2. Wherein does the use of nerve nostrums tend to impair the public health?

3. What measures, if any, can we take to lessen or destroy the nostrum-taking habit?

Longfellow plainly expressed a lack of faith in, if not contempt for, nostrums when he wrote

> Purge with your nostrums and drugs infernal
> The spouts and gargoyles of these towers; not me;

and reference to the meaning of the word "nostrum" shows at once the secret of the power they possess over the public mind.

"Nostrum," says a high authority, means "a medicine the composition of which is kept secret"; "a quack medicine"; and the key to the whole situation lies in the word "secret." The element of mysticism always holds our interest. It is that alone which gives the juggler's trick its charm. Remove our ignorance as to the manner in which the trick is done, and simultaneously you destroy our interest in the method of its performance.

Venders of nostrums, with a fine show of commercial shrewdness out of all proportion to any sense of common virtue, understand this frailty, this very common lack of logic on the part of the public mind, and trade freely on our credulity purely for commercial gain. They approach us from every side, in every place, and under all possible guises, with the most marvelous and glowing propositions designed to catch the public eye; then feed the little flame so adroitly kindled by dosing us with things about which we know nothing, and which we are pleased to swallow, in testimony of our simple faith.

The quack's secret is his own and forms his most valuable stock in trade, and often enough it is his only asset. Remove the seal of secrecy from his nostrums and his business of ruthlessly despoiling the public health and depleting the individual purse for the sole purpose of enhancing his own financial gains, will disappear like the mist before the rising sun.

Taking up the second proposition, viz.: Wherein does the use of nostrums tend to impair the public health? We may answer that the empirical use of any drug for the cure of a given disease is less logical and less scientific than if that drug produced specific action necessary for the relief of specific morbid conditions. This makes empiricism the basis on which nostrums are supposed to act; and this in itself might not be so bad in some cases if the disease for which the individual is being treated had first been correctly diagnosed.

But that is far from being the case. The mail bag with the quack takes the place of the instruments of precision and personal judgment of skilled physicians, so that the quack is doubly handicapped in his attempts to treat disease; first, by not knowing the nature of the disease he is treating, and secondly, by having to rely entirely on the less scientific principles of empiricism as compared with more rational forms of therapy.

Nostrums, however, do sometimes seem to effect a cure by suppressing the activity of symptoms in diseases like epilepsy. But, after all, it is only suppression, and not cure. In the Craig Colony report for 1898 we spoke of the matter as follows:

> And so it is that the manufacturers of patent nostrums and the great army of quacks who thrive throughout the land, find in the epileptic their readiest victim. They beguile him with vivid representations of wonderful cures and then deliberately set about to rob him of his honest means, and what is worse, of what little vigor of constitution he may possess. He is deceived with a drug that suppresses his attacks for a little time, but which does not cure, and which must be taken in such large doses that in time it destroys his mind and ruins his physical health. We are not giving hearsay evidence, but facts, and to make sure of such facts we tried one of the "surest cures" at the colony with the result that two patients were made temporarily insane.
>
> A young man of excellent family and personal attainments was admitted to the colony whose malady for the past year had been rapidly growing worse, and who had in his possession at the time of his admission 26 separate and distinct quack and patent remedies, all of which he had been using to some extent. He was at once relieved of them, with the result that he at once began to improve.

Two years later, after having collected much additional evidence of the infinite amount of harm nerve nostrums do in cases of epilepsy, we again referred to the matter in our annual report, citing the following case:

> C. B. M., a young boy, died at the colony September 24, from the direct effects of much drugging with "R.'s Nervine." He came to the colony first in January, 1897, remaining here a year and going away very much improved.
>
> While here he attended school, made very satisfactory progress and bid fair to be able in a few years to return to his home and take up some vocation. After returning to his home, he grew rapidly worse. He was then made to take "R.'s Nervine" in large quantities. He rapidly became stupid and apathetic, his circulation sluggish, his skin harsh and dry and his body covered with sores. Still his parents could not see that "R.'s Nervine" was the cause of the boy's deplorable condition and continued to give him the poisonous drug. He soon became so bad that he was returned to the colony, but the drugging with the nostrum had gone too far; he did not respond to proper treatment and died very shortly after his readmission. His mental condition, when he came back, resembled that of most pronounced primary dementia.

Numerous other instances similar to this, but in which the nostrum treatment was stopped before it had gone so far, have come under our observation; and we know that nostrums for other nervous diseases produce effects equally as disastrous; and the giving of powerful drugs to patients, concerning whose drug idiosyncrasies he is ignorant, is but another of the quack's dishonorable methods.

We come now to the third proposition, by far the most important of all, and that is: What means, if any, can we take to lessen or destroy the nostrum-taking habit? A well-known clergyman in the city of Rochester lately said, in a public speech, that "the widespread practice of such arrogant quackery as that which universally pertains to-day is a blot on every honorable physician's escutcheon"; and I fear the indictment stands on solid ground.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

As guardians of the public health, it is plain that the suppression of quackery is a duty we have not yet fulfilled. To make any impression for good on the unsavory practice will be a long and tedious uphill task, but this ought not to deter us for a moment, and it would seem that now, since the prospects seem so fair for cementing into a closer fraternal union the physicians of the entire country, is a good time to start the work on its way.

There are three things I have to propose that would be effective in lessening or destroying the nostrum evil. Two of them, while less effective than the third, are easier of application; while the third, which would be wholly effective in itself, could only be given force through national legislation.

The first is, an arrangement by which a continuous series of articles could be written for publication in the leading medical journals of the country, and which would specifically and unmistakably set forth the dangers of advertised nostrums; the same articles being afterwards published in the daily papers and in the literary magazines, in the form of standing advertisements if need be. Having the authoritative backing of the best medical journals, such matter would be bound to command attention and respect on the part of the public.

The second plan is to inaugurate in every city a course of lectures to show the evils of indiscriminate medication through patent nostrums, making the object lessons plain and forceful and placing the lecture course on a popular basis.

To carry out these plans would cost something, but there is no question that the money could be raised, either through private contributions, or by an assessment against the members of the medical profession.

The third plan, and the only one bound to be entirely effective if once established, is to have a national law regulating the manufacture and sale of nostrums and the practice of quackery, the feasibility and utility of which has been demonstrated in many countries abroad.

In Austria the sale of any nostrum or arcanum is strictly prohibited, and proprietary medicines may be sold only if their ingredients and the manner of compounding them have been made known. Such medicines, however, can not even then be purchased without physicians' prescriptions, unless they have been designated by sanitary authorities as harmless.

In the same country the law even undertakes to regulate the price to be charged for such preparations, for it provides that whenever the reasonableness of the price of a proprietary medicine is questioned, it shall be rated on the basis of the official tariff approved by the Austrian pharmacopoeors. It is evident that patent medicine men do not become millionaires in Austria.

In Belgium the law holds a pharmacist responsible for every drug sold by him, which provision applies to proprietary articles as well as to all others, and requires that in the sale of proprietary articles the composition of the same in detail shall appear in connection with its label.

The French government, the most advanced of any of the nations in this respect, in order to carefully guard the health of its citizens and to prevent the evils arising from the manufacture and sale of deleterious drugs and compounds, has from time to time passed strict laws and regulations covering the practice of pharmacy and the preparation and sale of chemicals for industrial and commercial purposes. The sale of medicinal compounds or remedies, the ingredients of which are only known to the proprietors, is absolutely prohibited in France. The law requires the inventors or owners of such remedies to communicate the formula of their preparations to the minister of commerce, with the list of diseases to which they are applicable, and a statement of the actual trial to which the medicines have been submitted. The National Academy of Medicine then examines the composition of the remedies to ascertain if their administration might be dangerous in certain cases; if the remedies are good in themselves; if they have produced or will still produce beneficial effects on humanity; the proper price is paid by the government to the inventor of a remedy recognized to be useful. This recompense is based on the merit of the discovery, on the advantages which have been obtained or which are to be obtained in curing human ills and on the personal advantages which the inventor has already derived from the remedy or may hope to derive from its adoption. An agreement is then drawn up between the minister and the inventor, ratified by a higher authority, and the secret published without delay.

In Germany the use of patent nostrums is greatly discouraged by the German government, and every notice or advertisement of this class of preparations must distinctly embrace an accurate analysis of the ingredients or component parts used in such preparations.

In Russia no proprietary medicines are allowed to be manufactured or sold, this country going further than any other by absolutely prohibiting the manufacture and sale of nostrums of all sorts.

With the English-speaking races it is radically different. In the Dominion of Canada the utmost latitude is allowed in the sale of such things, for they are sold in all grocery stores, the proprietors of which sometimes undersell the regular wholesale trade.

The same state of affairs exists in British Honduras, grocery stores here dealing in many of the ordinary drugs that are only sold by licensed apothecaries in this country.

In Brazil the law respecting the sale of chemicals, medicines, poisons and other proprietary articles is very strict, and if enforced can not help being of great benefit to the public and a protection to the physician, pharmacist and the druggist.

The Chinese government, on the other hand, has no laws regulating the sale of drugs. Chinese merchants, however ignorant of pharmacy, are permitted to sell drugs so long as they pay what is known as the "liken tax"; and to show the lax manner in which medicines are used in China, the United States Consul translates a prescription for "weak and diseased lungs," consisting of a "decoction made from gentian, apricot kernels and seven other medicines," without in any way indicating the name or nature of the last seven.

When the medical profession of this country decides to enlist the aid of Congress in formulating laws regulating the manufacture and sale of nostrums, it would seem that they might do well to try and avoid, on the one hand, the Scylla of overcaution, such as pertains in Russia, and, on the other, the Charybdis of utterly false therapeutic license run riot, such as pertains in China, and adopt a midway standard at once just to all, sensible and practicable, like that now in force in the French Republic, and which had its origin under the reign of the Emperor Napoleon in 1859. To aid in the enactment of such legislation would seem to be a

most natural thing for the Association to do, for its Code of Ethics reads as follows:

It is derogatory to professional character for a physician to prescribe or dispense a *secret nostrum* whether it be the composition or exclusive property of himself or others. For if such nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality, and if mystery alone gives it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice.

And, in conclusion, it seems pertinent to ask why the present is not as good a time as any for the American Medical Association to discuss plans for taking the matter to Congress in Washington.

HYPNOTICS, ANALGESICS AND RESULTANT DRUG ADDICTIONS.*

SMITH ELY JELLIFFE, M.D.
Clinical Assistant in Neurology, Columbia University; Visiting Neurologist, City Hospital.
NEW YORK.

Insomnia and pain are the banes of existence of the patient with any nervous affection, and from his standpoint are in themselves the maladies from which he is suffering. He prays his physician for relief from one or both, knowing, alas too well, that the market is full of drugs that will bring him relief. It does not often occur to him that the physician has any more complicated mental process to go through than merely to choose the right drug to bring healthful sleep and to banish pain. Insomnia and pain may each be the cause of the other, or they may be the outward symptoms of an exceedingly complex condition of derangement.

CLASSIFICATION OF INSOMNIA.

In trying to study the causes of sleeplessness I have found it helpful to remember the classification of insomnia that Sir James Sawyer lays down in his "Contributions to Practical Medicine." He says:

Cases of insomnia seem to divide themselves naturally into two groups, namely, of cases of what may be called *symptomatic insomnia*, and of cases of what may be called *intrinsic insomnia*. Symptomatic insomnia attends a vast variety of morbid states, and is secondary to them, or is part of them. Intrinsic insomnia, or insomnia per se, is a kind of wakefulness that seems to depend on the inability of the brain to adapt itself to the conditions of sleep.

Symptomatic insomnia, or the sleeplessness that is one of the symptoms of a disease attended by severe pain is not so difficult to treat, provided the pain, or the elevation of the temperature, or the coughing be the only cause. We may control it either by using hypnotics or sorporifics, or by giving drugs that will reduce the fever or diminish pain, or stop the cough; or we may combine the treatments, and use sorporifics in conjunction with the remedies that will remove the causes of pain or fever.

The family physician who uses sulphonal or trional for the purpose of inducing sleep in severe illness, employs one of the most valuable aids to recovery, for sleep as a natural remedy in disease is as necessary as any therapeutic remedy. But, at the same time, these drugs, if used continually, will of themselves cause the worst kind of insomnia, that in which natural sleep is absolutely impossible without the aid of a drug.

Intrinsic insomnia, to refer again to the classification of Sir James Sawyer, is due to various causes, which he divides into three groups, viz., the *psychic*, the *toxic* and the *senile*.

Psychic Insomnia.—It is taught that the brain in natural sleep is relatively anemic. When the brain is in full working activity the cerebral arteries are well filled with blood from which the brain cells are rapidly receiving nourishment and ridding themselves of waste. During sleep the blood flows more gently and in smaller streams through the brain; and the brain cells are not expending energy, but are storing it up. Anything, therefore, which tends to keep up the activity of the brain cells and keeps the blood circulating freely through the brain tends emphatically to keep the brain cells from repose and the patient finds himself sleepless. The psychic causes of such brain activity may be the habit of thinking over business or work after going to bed, worry, anxiety, excessive mental work that will not let the brain cells cease working for several hours after the real work stops, sudden grief or shock, or form of preying sorrow, remorse or loss of hope.

Toxic Insomnia.—The toxic causes of brain activity are due to some poison, that maintains the arterial supply of the cortex of the brain at such a height and so long that wakefulness is inevitable. These poisons may be in the form of drugs that have become a habit; alcohol, or the milder stimulants of tobacco, tea or coffee, or, on the other hand, the poisons may be certain accumulated waste products of the patient's own metabolism.

Senile Insomnia.—Senile causes of sleeplessness are due to the age of the arteries. As the smaller cerebral arteries lose their elasticity their walls grow weak, and they are physically unable to regulate the flow of blood to the brain which ought to be diminished at night to cause the sleep of youth.

On this brief classification of the causes of insomnia I would establish an outline of the kinds of treatment that are recommended by men of wide experience, with a discussion of the question of how far hynotics may be used to relieve insomnia and analgesics employed to alleviate pain without danger of resultant drug addiction.

THE DECLINE OF STOICISM.

In the first place, I would say that the demand for relief from minor pains and slight insomnia has increased with the supply of remedies. Although my experience is limited to some ten or twelve years of practice, and I can not with authority compare the older days with the present, yet I think I may safely say that people, as a rule, do not bear pain as bravely as they did before the days of anesthetics, analgesics and hypnotics. Such scenes of fortitude as Ailie's operation in Dr. John Brown's story of "Rab and His Friends," are, we are thankful to say, unnecessary now; but at the same time the day is past when women bore the pain of cancer, or the knowledge that they were dying of a tumor, to their graves without opening their lips to anyone save their physician. The brave serenity of spirit showed by Sydney Lanier, who was carried to his class room to give his lectures, and who never permitted his illness to be mentioned, and the gay stoicism of Robert Louis Stevenson, whose only reference to his hemorrhages were as to his friend "Bloody Jack, who was with him that morning," are examples of that heroism in suffering which I believe has become much more rare with the introduction of the many pain-relieving remedies.

Any sufferer may to-day, at the cost of ten cents, purchase temporary relief from a headache that is due to overwork, or an artificial night's sleep where sleep should have come naturally. To suffer is no longer deemed

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

brave, it is deemed ignorant; but the little knowledge that will bring relief is too often a dangerous thing.

The result of this easy and sure means of obtaining relief has led patients, and sometimes physicians, to be too easily satisfied with relieving pain and giving artificial sleep instead of ferreting out the cause of the trouble and removing it, as they were obliged to do in the old days if they would stop pain.

I do not purpose to speak of drug habits acquired by patients who treat themselves, except to say that every analgesic and every hypnotic is dangerous if used indiscriminately; and that all patients should be emphatically warned that there is nothing that they can take regularly and persistently to relieve pain or sleeplessness without doing themselves permanent injury. Paradoxical as it may seem, the least harmful drugs are often the most deadly. Fewer men and women ruin their nerves by the abuse of chloral than they do by the use of bromids. I have had many patients the victims of the bromo-seltzer habit, who took high moral grounds against the use of morphin and chloral. I have entered a business man's office and seen it stocked with a winter's supply of bromo-seltzer, with which he proposes, as was his wont, to ward off his regular afternoon headache; and I have had as hard a fight to bring him, by means of travel, exercise and diet, to a normal state of health as in breaking a morphin fiend of his habit.

It would greatly lessen the dangers of drug habits if family practitioners would encourage patients to endure a certain amount of the pain and sleeplessness of general diseases, never saying, "I will leave you something perfectly harmless that will make you sleep"; or, "I will give you something very new and very powerful that will stop that pain in ten minutes." The drugs for relief should, as far as possible, be combined in prescription with the drugs that treat the disease, or left without name or emphasis to be taken at the right time. In almost every case the abuse of phenacetin, antipyrin, acetanilid, the salicylates and allied products has begun by a physician calling especial attention to the efficacy and harmlessness of these drugs first prescribed to ease the pain and sleeplessness of some acute disease, such as tonsillitis or grippe.

THE USE OF FAKE SYNTHETIC FORMULÆ.

In this connection I can not refrain from calling attention to a large number of combinations of well-known drugs of this class that are given fake chemical formulæ, and which, while substantially mixtures of such remedies as antipyrin, acetanilid, phenacetin and allied synthetics, yet nevertheless are claimed to be new and important synthetic discoveries. It is to be regretted, moreover, that there are to be found physicians who will describe at great length and in much detail the wonderful cures which have resulted from the use of some of these impossible synthetics. All honor should be paid and support given to the enterprising chemist who has devised a really good new product. The profit that he may make from it is legitimately his, but physicians, as a class, I believe, are too prone to accept unchallenged the statements of some manufacturers who put out misfit combinations.

It is not expected that we as physicians should bear always in mind the chemical lore of our laboratory days, but a more careful scrutiny of the great flood of newer synthetics is advisable if not imperative. Moreover, when it is to be borne in mind that many of these so-called newer synthetics are sold for from fifty cents to one dollar an ounce, when their constituent parts may be purchased for from ten to twenty cents per pound, the robbery is made possible only under the guise of a trade name, and if the education of the physician is not sufficient to protect the public, then legislation is imperative.

HOW TO TREAT INSOMNIA.

As a rule the few doses of such drugs that are necessary to bring relief in acute diseases, whether to ease pain or to bring sleep, lead to no habit. As soon as the body has recovered its tone, and so soon as the cause of the pain is removed and the pain itself has disappeared, the body does not crave a repetition of the drugs. Even opium, in any of its forms, can be borne well and leaves no bad effect when intelligently prescribed. The sole danger in such cases, I believe, lies in the fact that the patient knows what has given him relief, and will, inevitably, tamper with the fascinating drugs when he has some minor ailment in the future. He then almost invariably runs a twofold danger: by continually giving himself relief from a pain that ought to be investigated he ignores the cause of his pain until his disease is pronounced, and in the meantime has by repeated use of the drug habituated his nervous system to overstimulation.

These cases in which pain and insomnia were at first merely secondary phenomena form a large percentage of the patients who afterwards come to us to be treated for the toxic form of insomnia *per se*.

In the severer grades of psychic insomnia it is often necessary to secure a few nights of artificial sleep at any cost; for the sleep of itself will in a few days induce sleep and the doses may be tapered off, or the need for them will stop naturally. In the cases of insomnia following sudden shock, great mental excitement, the anxiety attendant on strain of business, or the nervous state of worry in women that is accompanied by a hysterical breakdown, it is wise to give hynotics and to induce sleep until the body is thoroughly refreshed. In such cases many physicians prefer, I think, with good reason, opium or chloral, or their combination, although of late years the use of trional and sulphonal with some of the modifications of chloral, chloralamid, etc., have given excellent results.

Sir Lauder Brunton has suggested with much wisdom that a combination of hypnotics is more successful than any one of them singly. He recommended the now well-known mixture of small quantities of morphin, chloral and the bromids, and this is a favorite combination of a great many of us.

POPULAR KNOWLEDGE OF OPIUM UNDESIRABLE.

Whenever opium enters into the prescription for the relief of insomnia or pain, too much caution can not be urged. This is an oft-repeated tale, and yet from the crop of habitués of this drug that I see yearly, it seems not altogether to have been learned. At the same time, it is my own firm conviction that there is too much popular knowledge of the effects of opium, and personally I should condemn in the strongest possible manner the practice of the Woman's Christian Temperance Union of imposing on the public the 10 to 25 per cent. of information regarding alcohol and opium which they make obligatory in the publication of school books. The giving to the young and immature a knowledge of the seductive activities of any agent is, in my humble opinion, a practice worthy of the severest criticism.

THE NEWER OPIUM DERIVATIVES.

But this leads away from the last topic of my paper, the new opium derivatives. These, heroin, dionin and

peronin, as is well known, are derivatives of morphin; modifications by chemical substitution of groups of atoms. They are distinctly not morphin, and their activities have definite and distinct individualities. The pharmacologist who would alone register blood pressure, respiratory activity and heart beat, may maintain that these drugs have an identical action; but he does so on very meager and insufficient data. The psychologic manifestations of the activities of these drugs are distinct and in the genesis of drug habits, the brain and its activities is the all-important factor, heart beat and blood pressure are secondary.

Of the opium habit I need say nothing; physicians are acquainted with its general features, but in this day and generation what may happen on account of this widening out of our therapeutic possibilities?

I believe that just as phenacetin, antipyrin and acetanilid, trional and the newer chloral combinations have so richly supplied the profession with weapons to attack pain and insomnia and have thereby lessened the danger of the opium habit, so the introduction of the new morphin derivatives will afford a like refuge for those patients for whom opium seems imperative. They will lessen the great amount of the morphin habit even if at times they may induce a habit of their own. That they do is no question, but I have dealt with this subject elsewhere.

To my mind the question of drug habits, so far as the physician is concerned, in large part resolves itself into a number of simple restrictions that we shall place on ourselves. These may be expressed as follows:

CONCLUSIONS.

1. Prescribe the drug which will do the work required to produce sleep or relieve pain, but let it be so graduated with reference to dosage and choice of remedy that it will be the least harmful if used steadily.

2. Keep our mouths tightly shut as to what we are using. Do not say, "Take 1 gr. phenacetin, 10 grs. of salol, ½ gr. of codein." Give it to the patient if necessary, but do not under any circumstances permit him to know what it is. That is a medical question, and if the information is imparted its circle of pernicious activity radiates further than we can imagine.

3. Wage incessant warfare on the many pirates who provide all sorts of reliefs to the public, going directly to them through the lay press and the magazines.

4. In conclusion, let it be remembered that the introduction of newer drugs, rightly set forth by honest chemists and worthy clinicians makes most desirable accessions to our armamentarium; but that false pretense and economic robbery of an unsuspecting public deserve united condemnation and opposition.

DISCUSSION

ON THE PAPERS OF DRS. SPRATLING AND JELLIFFE.

DR. FRANK WOODBURY, Philadelphia—The author referred to the laws of China, but not to those of Japan, which present a marked contrast. The Japanese government apparently modeled its regulations of the sale of nostrums on the plan of Austria. It requires the registration of actual formulæ, and if any are found which do not correspond to the formula their sale is forbidden under penalty. Furthermore, if any compound or preparation is considered by the health board as injurious or dangerous, its sale is absolutely prohibited. Finally, those that are shown to be useful have their price regulated, so that the sick shall not be charged extortionate prices. These laws are not only in marked contrast to the absence of regulation in China, but they are also far in advance of our own.

DR. H. C. WOOD, JR., Philadelphia—Most of the members of the American Medical Association have decided views on the subject of self-medication and on the dispensing of medicine by the physician who thus invades the province of the pharmacist. I think that this practice is attended by great danger to both professions, and to the patients as well.

With regard to the suggestion of Dr. Spratling about instructing the laity, I think that it would be better to remove the beams from our own eyes before attempting to remove the mote from our brother's eye. For instance, many of the preparations now in use among physicians are nothing more than secret preparations. Only this afternoon, in coming into the room, I picked up a circular containing the advertisement of a preparation made by Rigaud and Chapoteaut, which is not only advertised to the profession, but is also advertised to the public in the daily papers for self-medication. The remedy for this evil is difficult to find. Dr. Spratling has suggested popular lectures as a means of instructing the public; perhaps some papers read before medical societies might afford a good introduction to the general discussion of the subject.

The final recommendation is not possible in the United States. The sentiment of the people would be against it as being antagonistic to American ideas. Much, however, can be done by the proper exercise of legislative control. The greater part of the protection to nostrums is due to the copyright laws. Probably the protection by copyright is more than is needed. If the profession would try to overcome the copyright protection of nostrums, it would accomplish a great deal toward breaking up this kind of self-medication by the laity.

DR. W. J. ROBINSON, New York City—The papers are both valuable and timely. The suggestion that physicians should contribute articles to be published in the daily papers is a good one; but to pay for their publication would cost too much. If the articles were well written, no doubt the papers would be glad to get them as matters of interest to their readers.

I am surprised to hear Dr. Spratling's remarks on the careful regulation of the sale of patent medicines in France. I have been in France myself, and that is not the opinion that I would have formed from my own observation. There is hardly an old wall in Paris that is not covered with advertisements of proprietary articles, and the little kiosks, or public urinals, are covered with directions for self-treatment for venereal disease and lost sexual power, the remedies to be bought at all pharmacists. Possibly the laws are on the books but are not enforced. Patent medicines are everywhere in evidence in Paris, even the illuminated kiosks at night are covered with announcements of new nostrums.

With regard to the remark about patients bearing pain much less than formerly, I believe this to be true. We can not go into the lying-in chamber without taking with us a bottle of chloroform or ether, and we use them for slight surgical operations, often, indeed, against our better judgment.

A remark has been made about physicians of the present day giving simple substances, instead of the complex preparations that were formerly in use. This is in the direction of more accurate and scientific prescribing. This has been recognized by the Pharmacopeia, and the physician now has at his command many articles in the form of active principles and simple substances that it was impossible to get formerly, except in combination. This is a fact known to every chemist; but the average physician is slow to understand it.

About the evils of self-drugging, everyone present can recall instances. I recall a patient who took, every day, sixty grains of phenacetin, and who claims that when he goes without it he suffers with headache. It is impossible to say whether the headache is really caused by the want of the phenacetin or whether a phenacetin habit has become established. Another patient who had a syphilitic headache when a young man, and was cured of it by the biniodid of mercury, for years afterward was in the habit of recommending this drug to his friends when they complained of having headache.

DR. W. L. DICKERSON, St. Louis—I have observed that, just at the close of the sessions for the last four or five years, there has been brought up for discussion this most interesting subject when there are very few to discuss it and very little time to do it in. It seems to me that, in trying to regulate

this matter of the use of proprietary preparations, we must begin with the profession itself. The pharmacists of my neighborhood can always tell when an agent for a drug manufacturing house is going around visiting physicians, because on the next day there will be several prescriptions calling for these special articles to be put up. Physicians know absolutely nothing of the composition of many of these preparations, and yet they take the statements of the agents, or the advertisements, as their authority. Certainly if a man makes a really valuable discovery or contribution to medical science, he should receive the advantages derived from the sale, but in that event he should patent the drug, and then we would know what it is that we use, for the composition must be made known of articles that are patented.

With regard to the habit of self-medication with narcotics, I think that there is a danger of such habits being formed if the physician places prescriptions of this kind in the hands of his patients indiscriminately. I am in the habit, when prescribing for a patient suffering with pain, to give a tablet of morphin from my hypodermic case and give a prescription for whatever else may be required. In this way, the patient gets the prescription without the opiate and there is less danger of forming the habit by refilling the prescription.

DR. W. P. SPRATLING, Sonyea, N. Y.—The tone of one of the speakers would seem to indicate that general legislation could not regulate the manufacture and sale of proprietary medicines in the United States. Such may be the case, but I thing that the profession can secure some legislation if an effort is made. We can get laws to control the adulteration of food supplies, and I think the necessity for the protection of the public against injurious medicines is just as great in some instances as that of securing better food. The statements I made concerning the regulation of drugs in foreign countries was taken from consular reports made to the Department of State in 1898.

DR. S. E. JELLIFFE, New York—The proposition seems to me to be a very simple one, and one that could probably be settled in five minutes if we, as a profession, were all ideal ourselves; but we are not all ideal by any means. For instance, I have known this to occur: In New York City a very enterprising manufacturer devised a scheme to increase the sale of his particular produce. He issued pads, with printed prescriptions; each one had a coupon attached; for every one of these coupons representing orders sent to the drug store, the physician would receive 25 cents. If there are physicians of such character among us as to stoop to participate in a scheme like this, what can we say to the public or to the manufacturer of proprietaries?

COMMITTEE APPOINTED TO MAKE RECOMMENDATIONS.

DR. A. W. BAER, Chicago, moved that a committee of three members of the section be appointed on the subject of these papers, to report at the meeting of the section in 1903, making such recommendations as they think fit. The resolution was unanimously adopted and the chair appointed to serve on the committee, Drs. Baer, Robinson, and Wood.

A FURTHER STUDY OF THE INFLUENZA BACILLUS.*

F. ELDREDGE WYNEKOOP, M.D.
Professor of Biology, University of Illinois; First Assistant Bacteriologist, Chicago Board of Health.
CHICAGO.

Of recent years such thorough study has been given by so many competent observers to systemic conditions produced by the *Bacillus influenza* in the human organism, that we may say we are fairly familiar with and able to recognize all the important points in the general symptomatology of influenza. There are special conditions, however, concerning which we are not so well informed, and to direct attention to what may be called "some of the atypical manifestations of the influenza bacillus" is the purpose of this paper. The pathologic states of the mucous membrane which may be produced by the growth and development of this micro-organism on them are of sufficient gravity to warrant careful consideration. During the past five years a great many hundred cultures which were made from inflamed throat, nasal mucous membrane, eyes, etc., have been examined and it has been found that many of these local disorders were dependent on the action of the influenza bacillus, and not on the pyogenic bacteria. In a report published in the Bulletin of the Chicago Department of Health, January, 1899, I referred to some of the pronounced local disturbances which had been observed to be due to the Canon-Pfeiffer bacillus. The numerous observations made since that time confirm the statements then made. Attention was called to laryngeal, pharyngeal, nasal and ocular conditions—all severe types which were caused by the influenza bacillus.

In cases which were clinically laryngitis pure cultures of this organism were frequently obtained. The patients in the majority of instances presented symptoms which did not vary from those of acute catarrhal laryngitis. A feeling of rawness, tickling sensation, hoarseness and disposition to cough were the usual manifestations. Occasionally the symptoms were decidedly croupy in character, marked hoarseness, difficult respiration and a harsh, ringing cough were present. The mucous membranes were bright red, and in severe cases much swollen. The bacilli were found in the expectorated sputa and also in cultures made from these secretions.

In other cases which presented the usual clinical aspects of pharyngitis and tonsillitis the Pfeiffer bacillus appeared to be the exciting cause. Many times I have made bacterial examinations of exudations from mucous membranes which were congested, red and swollen and found no other organism. In many instances coming under observation the throat symptoms were so marked that a physician would feel justified in pronouncing the cases diphtheria, yet the Klebs-Loeffler bacillus was not found, although repeated examinations were made. Redness, swelling of the tonsils and well-developed membrane—manifestations certainly suggestive of diphtheria—have frequently been demonstrated to depend on the influenza bacillus. Indeed, cultures have been sent to the city laboratory many times for diagnosis which were taken from cases in which the probable clinical diagnosis was given as diphtheria by the attending physician, but instead of the diphtheria bacillus being found the influenza bacillus has been obtained in conditions almost pure. The power of this organism to excite such grave local disturbances is deserving of thoughtful inquiry and greater consideration than has heretofore been given to it. The proper treatment demands it. Diphtheria antitoxin administered to a patient suffering with a diphtheritic inflammation dependent on the Canon-Pfeiffer bacillus would fail to produce the desired results.

It would seem that when the influenza organism enters the system its field of action is not limited to some particular part of the body as that of many other pathogenic bacteria, but that it attacks and spends its force on any and every organ which offers least resistance. A throat may become the seat of severe manifestations and exhibit clinical symptoms—as already noted—differing not greatly from diphtheria, or in milder cases, from tonsillitis. The stomach and intestines do not escape this minute fungus, its activity in the one case producing gastritis, and in the other a condition simulating typhoid fever. It may advance along the eustachian tubes and

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. Arthur R. Reynolds, George Cook and Heman Spalding.

enter the middle ear and excite otitis media. It may find its way into the pleural cavity and develop pleurisy, a pleural effusion or possibly an empyema. It may enter the nasal cavity and cause an acute nasal catarrh, or a "cold in the head," with all the attending unpleasant features.

In the bulletin above referred to attention was called, in a paragraph which I quote below, to certain eye disorders which were produced by the Pfeiffer bacillus.

It has occasionally been observed by physicians that when influenza is present in a household the eyes of some members of the family suddenly become inflamed, accompanied by severe pain, swelling and redness of the conjunctiva, with a profuse discharge of pus. In that the disorder differed materially from ordinary acute conjunctivitis it was suspected that the *Bacillus influenza* might have something to do with the diseased condition. Cultures were made from the discharges, and the suspicion was verified by finding great numbers of the influenza organism.

Since these conditions were noted many cases of a similar nature have been studied, and like results obtained. The attention of the patient is usually attracted to his eyes because of a feeling which causes him to believe some foreign body has lodged on the conjunctiva. An examination at this time reveals a slight redness of both ocular and palpebral membranes. Very rapid development follows so that within a few hours the disease is well established. Abruptness of onset, rapidity of development and shortness of duration are the characteristic features of all the cases, whether mild or otherwise. At their height the severer cases presented symptoms strongly suggestive of blennorrhea, or conjunctival diphtheria. Pain, redness and swelling of the conjunctiva, discharge of pus and sometimes membranes were present, but, under antiseptic treatment, all these distressing manifestations disappeared as quickly as they came, thus marking the illness as different from gonorrheal or diphtheritic conjunctivitis.

Many cases coming under observation are worthy of mention; three, however, will suffice to illustrate the manner of action of the influenza bacilli when attacking this organ:

CASE 1.—Mr. O., aged 26, consulted me during the last week of March, 1902, with reference to his eyes. A few hours previous he became conscious that one of his eyes had somewhat suddenly become painful, and that almost immediately the other organ had presented a similar state. Believing that some foreign substance was the cause of his discomfort, he had by various methods attempted to remove it, with the result that he aggravated his condition. An examination revealed the ocular and palpebral conjunctiva much ingested and very red—the congestion being most pronounced at the fornix and on the lids. A watery discharge, which was slightly cloudy, collected at the inner canthus, from which cultures were made on blood serum. After twelve hours' incubation a number of colonies had developed, which were found to be made up of influenza bacilli. Sublimate solution, strength 1/5000, was ordered to be used every three hours. Within twenty-four hours after treatment was begun there was decided improvement, and at the end of a week the disorder had subsided entirely.

This case is a type of the mild form of infection with the influenza organism. The lids were not swollen or edematous, and the discharge at no time became thick or purulent, but remained a watery character. The milder cases are met with much more frequently than the severe types described below, and because of the color of the conjunctiva are referred to as "pink eye." Whether the Pfeiffer bacillus is the active etiologic factor in all cases of so-called "pink eye" I can not say, but that it holds a prominent place in the etiology of the majority of such infections I am inclined to believe.

CASE 2.—Mr. G., aged 47, while returning from his office, 5:30 p. m., March 7, 1902, became conscious that his right eye had rather suddenly begun to pain him. The sensation, as he thought, was due to particles of dust beneath the lids. Within an hour considerable swelling and redness of the conjunctiva and a watery discharge appeared. By 9 a. m. next morning—at which time I saw the patient—the pain was of a severe character, the swelling and edema so marked that the lids could be separated but little, and the discharge was of a thick mucopurulent nature. During the morning the left eye became involved, but did not present the severe symptoms that were present in the right. This less severe course I attribute to early treatment. The lids of this eye did not become swollen, the conjunctiva, however, both ocular and palpebral, were red and extremely sensitive, the discharge was watery in character, very little pus being present. Sublimate solution was used every two hours for twenty-four hours, with prompt and decided improvement. This same treatment was continued at less frequent intervals until the diseased state had disappeared, which was about five days in the case of the left eye, and eight days in the case of the right eye. Cultures made at the time of the first examination demonstrated the presence of the influenza bacillus.

A case of special interest has been observed by Dr. F. A. Phillips, Chicago, a report of which he kindly furnished me and which is herewith submitted:

CASE 3.—M. M., a little girl, aged 4, about 11 o'clock on the morning of Feb. 22, 1899, complained to her mother concerning her eyes. At this time a slight discharge was apparent, and the child seemed somewhat indisposed. During the next twenty-four hours the symptoms developed with great rapidity, so that, when the little patient was seen by myself at 6:30 p. m. on the same day, the eyes presented a serious inflammatory involvement. The lids were edematous and overlying; the integument was glazed and red, and the cilia matted with thick tenacious discharge. Only with difficulty could the child open the eyes, and then not to any extent. The swelling continued, and by 8 o'clock the upper lids became too heavy to be raised by the levators. By forcible separation and eversion false membranes covering both superior and inferior palpebral conjunctiva were exposed. The removal left small bleeding points. Beneath the superior ocular conjunctiva of both eyes a sub-conjunctival ecchymosis had appeared. There was no involvement of the cornea or iris. Mild constitutional symptoms were present—general languor, slight depression and low fever—which conditions were not observed in the other cases seen during the year.

Before instituting treatment cultures were made from the false membranes and surfaces beneath. These were examined by Dr. Wynekoop of the city laboratory, who reported the negative finding for all pathogenic bacteria except the bacillus of influenza, which seemed to be present in a pure culture. On the 24th inst., and again on the 25th, the treatment was discontinued for three hours and cultures made, which proved to be growths of the influenza organism.

The treatment was antiseptic in nature, and soon after its institution the conditions improved. The membranes reformed within five or six hours after their removal, but quickly disappeared on the use of sublimate solution. Recovery progressed steadily and by the end of the seventh day the edema had all subsided, the ecchymosis had faded, and only a slight hyperemia and thickening of the conjunctiva remained, which entirely disappeared soon after. Throughout its entire course the case was one presenting an unusual symptomatology. All the clinical manifestations—the sudden, severe beginning, the rapid development, and the comparatively rapid disappearance of the acute violent symptoms under treatment, without complication or sequelæ—were at variance with any other eye affections. These facts, together with the bacteriologic findings, led to a diagnosis of influenza.

The case reported by Dr. Phillips is one of the severe types and presents several interesting features which were not present in the other cases described, yet in general it followed the same course.

It deserves mention, as a matter of no small interest, that the clinical course of this local disease coincides in all the essential points with systemic or general infection, and that the duration and departure of the clinical conditions are in harmony with all the vital phenomena manifested by the influenza organism. Thus, the life cycle of the bacillus is short, a culture thrives but a few days, the resistance to harmful agencies is feeble, and under the most favorable surroundings the organism soon dies. Herein, perhaps, we find an explanation for the rapid recovery of the disordered eye when treated antiseptically. In view of what has been observed it appears that we have to do with a pathologic condition which differs materially from other acute inflammations of the eye. And in view of its abrupt and somewhat violent onset, its rapidity of development, its shortness of duration, and in view of the repeated findings of the bacillus of influenza, it would seem that we are justified in making a diagnosis of influenza ophthalmia.

In the *New York Medical Journal* of Feb. 1, 1902, appears a translation of an extract of a paper published by Dr. F. Rymowitch in the August, 1901, number of *Roussky Archiev Pathologyi, Klinitcheskoy Meditsinyi Bacteriologyi.* It appears that this observer has recently made a comparative study of the *B. influenza* and the bacillus of Koch-Weeks, and concludes they are one and the same organism. He finds that they are identical in morphologic, biologic and pathogenic characters. Both produced intoxication without a general infection. The most conscientious study did not reveal to him any differences between the bacteria, and he therefore believes that the bacillus of acute contagious conjunctivitis and that of influenza are the same. When attacking the mucous membranes of the respiratory tract the influenza bacillus produces influenza, and when affecting the mucus of the eyes produces acute contagious conjunctivitis, which disorder, according to Rymowitch, is the same as that produced by the Koch-Weeks bacillus. Not having had an opportunity to make a comparative study of these two organisms, I am not in a position to confirm or refute the observations made by Dr. Rymowitch. The subject is an interesting one, and because of its importance deserves further consideration, which I hope to give it in the near future.

THE FLY AS A CARRIER OF TYPHOID.

AN INQUIRY INTO THE PART PLAYED BY THE COMMON HOUSE FLY IN THE RECENT EPIDEMIC OF TYPHOID FEVER IN CHICAGO.

ALICE HAMILTON, M.D.

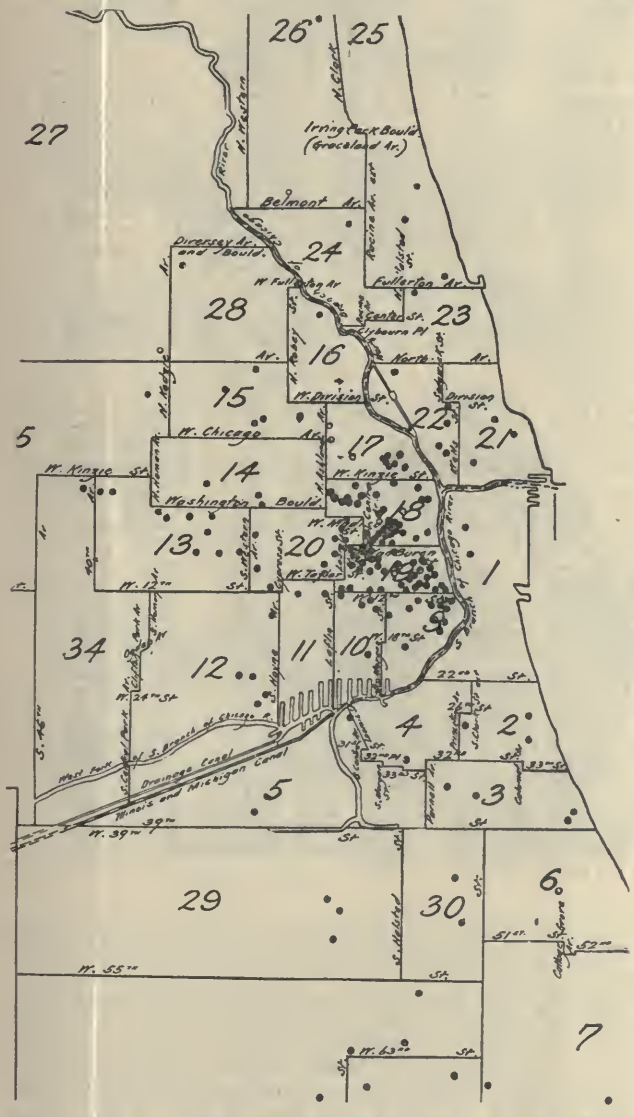
From the Laboratory of the Memorial Institute for Infectious Diseases.

CHICAGO.

During July, August and September of 1902 there was an unusually severe epidemic of typhoid fever in Chicago, which raised the death rate to 402 from this disease alone, as against 212 during the same three months of the previous year.

CHICAGO'S WATER SUPPLY.

The water supply of Chicago comes from the lake and is collected at five pumping stations: the Hyde Park station, which is two miles from the shore; the Fourteenth Street, four miles from shore; the Carter Harrison, two and a half miles; the Chicago Avenue, two miles, and the Lake View, two miles out. The Carter Harrison station is considered the best, the Fourteenth Street is almost as good. Specimens of water from each station are examined daily in the laboratory of the Chicago Board of Health and a bulletin as to the condition of the water at each is published in the daily papers. The state of the water varies greatly from day to day, and the practical value of these daily bulletins becomes somewhat problematical when one considers that twenty-four hours must always elapse between the collecting of the water and the published report, so that people who read on Tuesday morning that the water at a certain station is bad and take precautions accordingly are a full day late, for they were drinking the bad water on Monday. On the whole, such a statement as is made at the end of the week by the health department, "the water at this station averaged 60 per cent. good for the week," is really misleading, since nobody can ever know until too late which days made up the 40 per cent. bad. As a usual thing the water is worst when the rainfall is greatest, the sewage being carried farther out into the lake and contaminating the water at the intakes, except when there is the fortunate coincidence of light easterly winds, which, without stirring up the bottom, keep the sewage in toward the shore.



In discussing the causes of this greatly increased mortality from typhoid fever, Dr. A. R. Reynolds,[1] commissioner of health, speaks as follows:

"At the time" (the early summer) "there was nothing in the condition of the water to cause alarm. Notwithstanding the heavy rainfall of the previous months, the supply from all sources averaged 72 per cent. good (by 'good' in the laboratory characterization is meant a water free from pathogenic organisms, the colon group). But in the early part of August the typhoid deaths suddenly jumped up from a previous weekly average of 8.8 to 28 in the first week of August, to 44 in the second, and to 53 and 51 in the third and fourth weeks, with a total of 194 for the month, as against a total of 44 for July. As already stated, the water supply in July and previously was not of such a character as to account sufficiently for the increase of typhoid; but a study of the meteorologic conditions of the period beginning in October, 1901, reveals what are believed to be strong contributory causes. October, November and December, 1901, and January and February, 1902, were the dryest five consecutive months on record in 53 years. During the period only 6 inches of rain fell, instead of the average 11.84 inches. In November only 0.85 of an inch instead of the average 2.68, and in January only 0.64 instead of the average 2.07. There was no sewer-flushing rainfall during the entire period, and the city sewer flushing, always inadequate, was wholly suspended in January on account of the lack of funds. The sewers were congested with filth, of which typhoid stools formed a component part, and the surface of the earth, in city and country alike, was covered with the five months' accumulations. The water supply was, however, uniformly good, since there was little sewage movement. From March to July inclusive was the wettest season on record—a total precipitation of 23.73 inches instead of the usual 7.87 inches. The sewers were repeatedly flushed out, and the accumulated surface filth was washed away into streams, ponds and the lake. Under ordinary circumstances the water supply would have been repeatedly and grossly polluted. Fortunately, the wind movement during this wet period was unusually light and its prevailing direction was from the east—thus keeping the sewage-laden shore waters away from the tunnel intakes. In August a succession of high variable winds set in, the strongest being from the west. The lake bottom was vigorously stirred up by high wave action, the sewage was drifted to the intakes, and the water supply from all sources became so contaminated that it averaged only 38 per cent. good for the month.

1. Chicago Medical Recorder, 1902, vol. xxiii, p. 219.

CAUSES OF TYPHOID INFECTION ASIDE FROM POLLUTED WATER.

This pollution of the water supply was undoubtedly the greatest causative factor in the epidemic of the past summer, but there are one or two subsidiary factors which are not brought out in the report of the board of health, and which yet may serve to explain the peculiar localization of this epidemic. The accompanying Map 1[2] shows that a comparatively small area on the West Side was the region most severely affected. Within the limits of the Nineteenth Ward, which contains only one thirty-sixth of the total population of the city, there were between one-sixth and one-seventh of all the deaths

Map 1.—Showing the central part of Chicago and the approximate locations of typhoid fever deaths in August, 1902. (For map showing the entire city with the source of water supply and the sanitary drainage subdivisions, see THE JOURNAL, Dec. 20, 1902, p. 1563.)

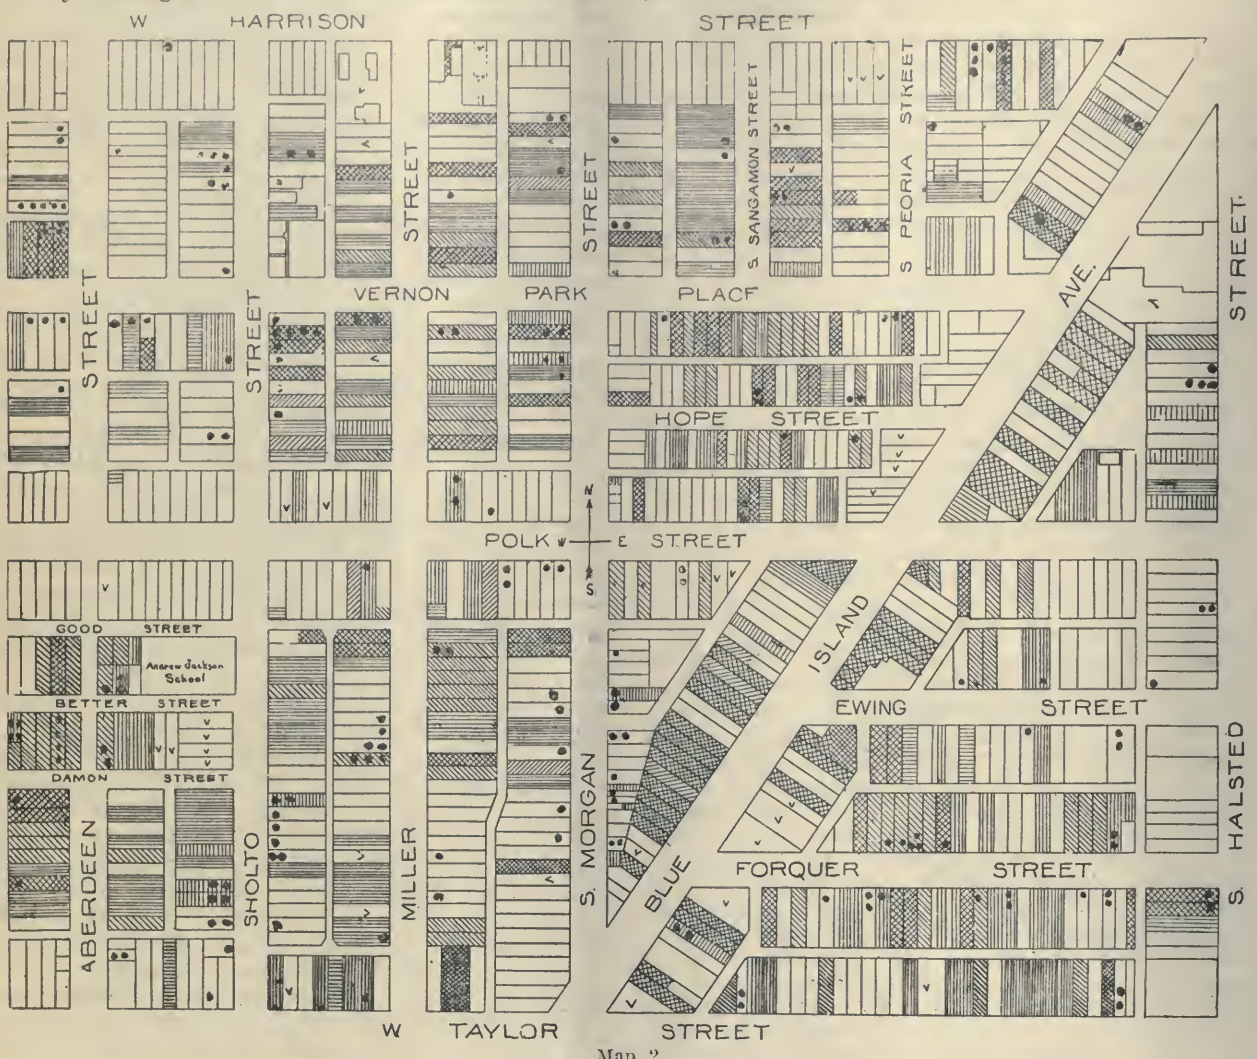
from this disease. This part of the city is inhabited largely by working people. It contains one of the largest Italian quarters, most of the Greek colony, a small Bohemian colony, the northern end of the Jewish quarter and the western part is chiefly American-Irish. So far as the general intelligence of the inhabitants is concerned, their knowledge of the laws of hygiene, their general housing conditions, cleanliness, overcrowding, etc., this part of the city does not differ from the other semi-foreign quarters, yet it suffered much more than any in this epidemic. Evidently there must have been some local conditions which favored the spread of the infection. The drinking water alone could not be responsible, for this part of the city is supplied from the Chicago-avenue and Fourteenth-street tunnels, the same water supply as that for the whole region between 47th and Lake streets, Canal street and Western avenue. Nor could the milk be chargeable, for though in this neighborhood the milk is often badly diluted, yet it averaged quite as good as that supplied to a prosperous residence district to the west, as shown by analyses made of the milk of both districts by the University of Illinois in 1898.

FAULTY SEWAGE CONDITIONS.

To those who studied the distribution of the cases of typhoid fever it soon became evident that the number was greatest in those streets where removal of sewage is most imperfect. This is an old part of the city, the sewers in many of the streets were laid before the great fire, at a time when the neighborhood was more sparsely settled and when usually not more than one family occupied each house. Adequate at that time, they are far from adequate now, and it takes only a moderate increase in the rainfall to make the sewage back up into vaults and closets, while clogging is of common occurrence in dry weather. The yards and closets are often below the level of the street and are therefore easily overflowed. Last spring during the flooding rains it was no uncommon thing to see one of these yards, from six to fourteen feet below the level of the street, covered with several inches of foul water which in the neighborhood of the privy was distinctly sewage-contaminated. In this way the earth of the yards and that under the basement tenements became soaked with diluted excreta.

This condition of things is made possible by the primitive arrangements for the disposal of dejecta which prevail in this part of the city. Two of the residents of Hull House, which is situated almost in the center of the typhoid district, made a careful house-to-house investigation, noted the conditions as to drainage in each house and also the number of cases of typhoid fever which had appeared in each during the three months in question. The results are shown in the accompanying Maps 2 and 3. It may be remarked in passing that there was no other way of ascertaining these facts except by such a house-to-house canvass. There are no records in Chicago of sewer connections which antedate the great fire. The records were destroyed at that time and have never been replaced.

It will be seen from the maps that the methods of disposal of excrement in this neighborhood have been divided into five classes. The first class includes such equipment as complies with the law: plumbing with adequate water-flushing, traps and a periodically cleaned catch basin; in other words, modern sanitary plumbing. This form of plumbing was made obligatory for all buildings by an ordinance passed in 1896. The second class includes imperfect plumbing or legal plumbing so much out of repair that the excrement is not completely carried away. In several instances very bad leaks were found, the fluid overflowing on to the floor, and in two instances trickling through the ceiling and dripping into the tenement below.



The third class includes out-of-doors water closets, whose water supply is the rain water from the roof and the wash water from the kitchen sink. This is a fairly safe arrangement when the catch basin is kept clean and the sewer does not back up. The law requires catch

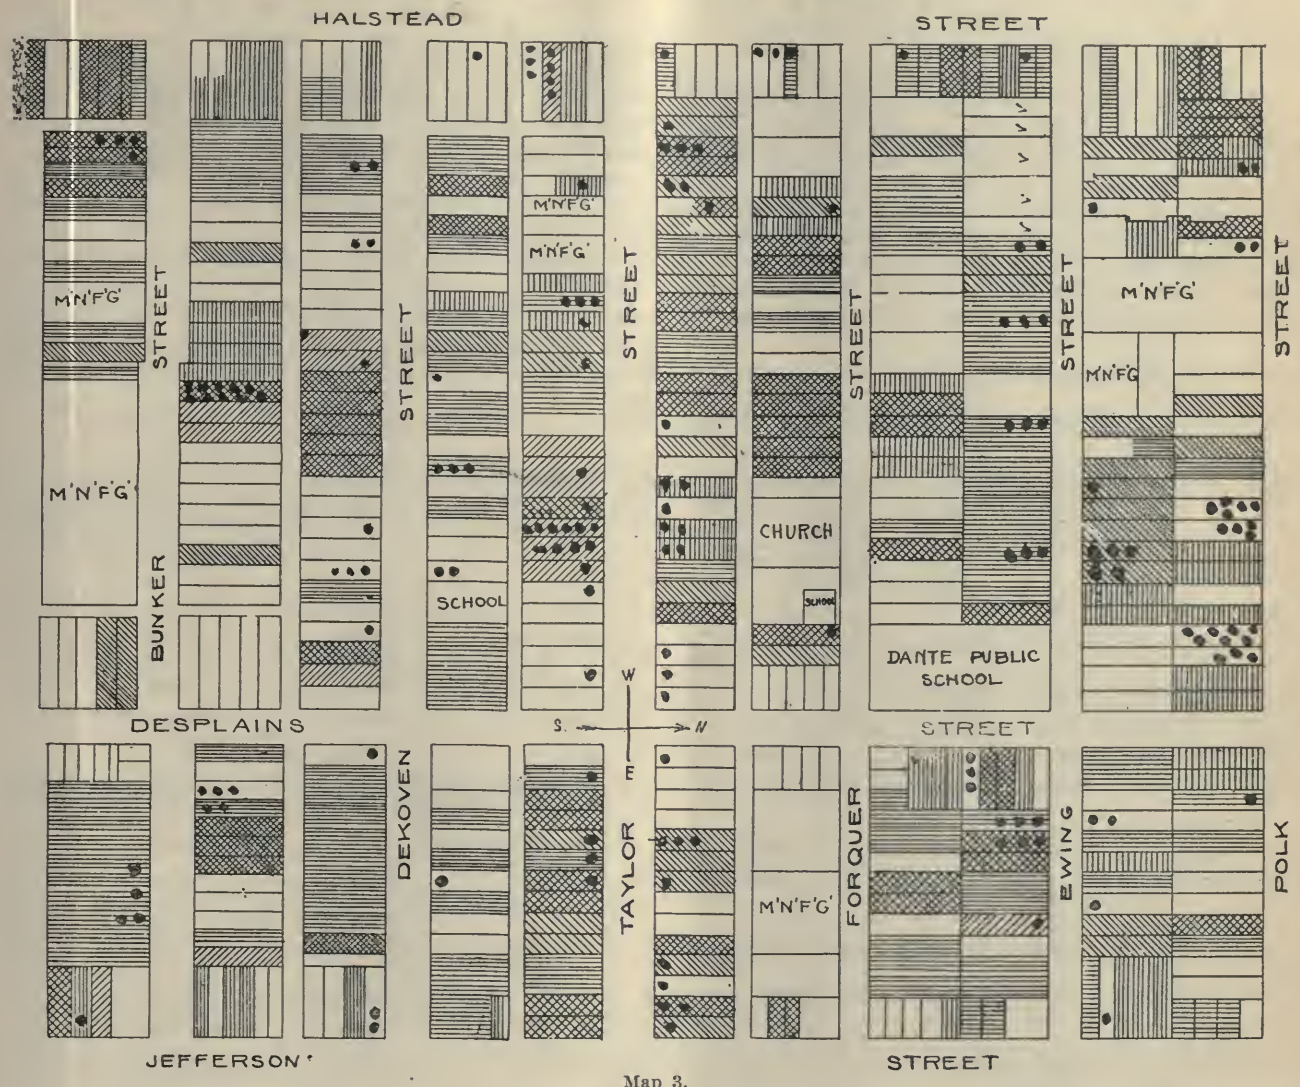
2. Prepared by the board of health and kindly given me by Dr. Reilly, Assistant Commissioner of Health.

basins to be of easy access and frequently cleaned, but many of them are buried deep in the earth and uncovered only when the accumulation of filth has become unbearable.

The fourth class includes the privy vaults with sewer connections but without water supply. These are cleaned either by flushing with a hose connected with the hydrant or by a scavenger. If cleaned often enough by flushing the sewer connection can be kept open; otherwise the night soil must be removed by a scavenger. It can be seen that there is room for great variation in this class. When the landlord lives on the premises he is apt to flush his privy at least twice a year, sometimes even once a month, but in the houses of absentee landlords the place may be flushed only once in three years or more. In some places it is impossible to ascertain whether or not there is any sewer connection, as no cleaning has been done in the memory of the oldest tenant.

The fifth class includes the old-fashioned country privy; no sewer connection, simply a hole in the ground.

Map 2.



Explanation of Maps 2 and 3.

It is often full and indescribably filthy, in spite of all efforts on the part of the tenants to keep it at least outwardly clean.

As can be seen from the maps, the cases of typhoid fever were not more numerous, on the whole, in houses where the disposal of fecal matter is most defective. Houses with good plumbing which are close to those with badly-drained cesspools are just as apt to have cases of typhoid as are the badly-drained ones, e. g., Morgan street on the east side. All that can be said is that in those areas which have many such places there was more typhoid than in those in which conditions are better. (Compare Bunker with Taylor street, for instance, Polk street east of Halsted with Polk street west of Halsted, Harrison with Sholto.) It must be remembered that the character of the plumbing is due largely to the newness of the building and to the conscience of the landlord, and is not a measure of the standard of living of the tenants.

The statistics which the Hull House residents were able to gather as to the number of cases of typhoid fever are as accurate as such statistics ever can be. No cases

were entered on the maps which had not had a physician's diagnosis, and inasmuch as the physicians of the neighborhood testified that there was an unusually large number of cases of "walking typhoid," many of which very likely never saw a physician, it is probable that the number of cases, as given in the maps, is below rather

Map 3.

than above the actual number. It was also impossible to show on the maps the actual condition of the various closets. Cesspools filled to overflowing and leaking are necessarily represented by the same shading as moderately full and periodically cleaned cesspools, to avoid overcomplicating the maps. A few extracts from the note-books of the Hull House residents will give an idea of some of the conditions found:

DeKoven street (Jewish). Vault, connected with the sewer, but full. Basement full of sewage-contaminated water from backing up of sewer.

Law avenue (Greek). Seventy-six persons using 3 small closets under the house; very filthy; apparently no sewer connection.

Bunker street (Bohemian and Polish). Unconnected vaults; very foul; 10 cases of typhoid fever, with 4 deaths in this tenement.

Law avenue (colored). Connected with the sewer, but out of order; full to the floor. Boards at back are broken away so that cesspool is quite exposed.

Ewing street (Italian). Cesspool, said to have sewer connection, but full and running over, so that stream of sewage runs down the yard.

Taylor street (Italian). Old-fashioned privy; no sewer connection. One of five privies in a yard between a 4-story front tenement and a 3-story rear tenement. While we were inspecting it, a woman came down with a vessel filled with discharge from a typhoid patient, which she emptied into the vault. No disinfectant was used.

Aberdeen street (Irish). One large vault, used by 16 families; very foul-smelling; unconnected with the sewer. This was cleaned by a scavenger during August, and the filth left standing in an open barrow in the alley between two houses for a week. It was so offensive that the tenants in these two houses were obliged to keep their windows on that side closed. Complaints to the health department and garbage inspector were fruitless, and finally the personal influence of a physician prevailed over the landlord and he removed it, but not until it had stood there during a week of warm weather when, naturally, the place swarmed with flies. There were five cases of typhoid fever in each of the two houses next to the alley.

INFECTION BY THE HOUSE FLY.

Now if there is any causative relation between the condition described above and the distribution of the cases of typhoid fever the agency of flies at once suggests itself as a possible factor. It is true that germ-laden dust blown by the wind may also be a mode of conveyance of the infection. The typhoid bacillus has been shown by Firth and Horrocks to retain its vitality in dry soil for twenty-five days, by Uffelmann for over sixty. However, it was only after the middle of August

that this agency could have come into play to any great extent, for up to that time there had been constant rains and there was practically no dust.

The importance of the common house fly in the spread of typhoid infection was emphasized by Majors Reed, Vaughan and Shakespeare in their report on the "Origin and Spread of Typhoid Fever in the U. S. Military Camps During the Spanish War in 1898." They state that in many of the camps:

> Flies were undoubtedly the most active agents in the spread of typhoid fever. Flies alternately visited and fed on the infected fecal matter and the food in the mess tents. More than once it happened when lime had been scattered over the fecal matter in the pits, flies with their feet covered with lime were seen walking over the food. Typhoid fever was much less frequent among members of messes who had their mess tents screened than it was among those who took no such precaution. Typhoid fever gradually died out in the fall of 1898 in the camps at Knoxville and Meade with the disappearance of the fly, and this occurred at a time of the year when in civil practice typhoid fever is generally on the increase. . . . The first pits at Knoxville contained, before the first twenty-four hours had passed after the arrival of the troops, fecal matter infected with the typhoid bacillus. Flies swarmed everywhere. Instead of abating, the disease increased. The soldiers were using the same water used exclusively by the inhabitants of West Knoxville, and among the latter there was not at that time a case of typhoid fever. Certainly the disease was not disseminated through the drinking water.

Dr. H. A. Veeder,[3] writing on the same subject in the fall of 1898, said that in his opinion flies were more important agents in the spread of typhoid infection in the military camps during the late war than were drinking water or milk.

There have been several mysteriously spreading epidemics, in farming regions, for instance, where the houses are far apart and where the spread of the disease can not be accounted for by infected water or milk; also puzzling instances of individuals, who have taken all usual precautions during an epidemic, and yet fall prey to the disease. These cases may best be explained by assuming that the food became infected by flies which had previously fed on typhoid discharges.

In a recent number of the *British Medical Journal*[4] there is a report by two British army surgeons, Majors Firth and Horrocks, of an investigation into the "Influence of Soil, Fabrics and Flies in the Dissemination of Enteric Fever." I quote simply the last part of the paper, that which deals with flies.

These investigators had adult and larval flies placed in a specially-constructed cage in which were also placed Petri dishes containing a mixture of syrup, a fresh typhoid stool and a fresh culture of typhoid bacilli, and sometimes the whole was lightly covered with earth. After feeding on this the flies would settle on other Petri dishes which contained sterile culture medium. The typhoid colonies were recovered in every instance.

TABLE OF CULTURES BELONGING TO COLON-TYPHOID

	Morphology.	Gelatin Plate After Forty-eight Hours.	Agar Plate (Hiss) After Twenty-four Hours.	Potato.	Gel. Stab.	Agar Streak.
Typhoid control No. 15.	Short, slender rods, rounded ends, spore-less, very actively motile; decolorizing by Gram.	Deep colonies are small, yellowish, granular, round. Surface colorless, delicately veined, edge lobulated. Center turning yellowish.	Deep colonies are greenish, bristly or thready, small. Surface colorless, granular, greenish center.	Moist, slightly slimy, colorless, growth, scanty.	Delicate, granular, growth along stab, thin, greenish on surface, not spreading much. No liquefaction.	Whitish, shining streak, even round'd borders, spreading very little. White precipitate in water at bottom of tube.
A 1 from vault	Same	Same	Same	Same	Same	Same
A 2 from yard.	Same	Same	Same	Same	Same	Same
A 3-a from yard	Same	Same	Same	Same	Same	Same
P 1-a from yard	Same	Same	Same	Same	Same	Same
P 2 from sick room.	Same	Same	Same	Same	Same	Same
A 3-b from yard	Same	Same	Same	Moderately abundant growth, slightly yellowish. Potato brown in two days.	Same	Thin, grayish, spreading more than 15.
P 3-a f'm vault	Same	Same	Same	Same. Potato brown in 24 hours.	Same	Same
A 3-c from yard	Same	Same	Same	Like 15	Same	Same
P 3-b f'm vault	Not so actively motile as 15.	Same	Same	Dry, granular, brown growth, all over surface.	Same	Same
A 4 from yard.	Like 15.	Same	Same	Like 15	Same	Same
P 1-b from yard	Same	Same	Deep colonies brown, granular, large, smooth-bordered. Surface, large, granular, brown.	Same	Same	Like 15
P 3-c f'm vault	Not so actively motile as 15.	Same	Same	Abundant, slimy, colorless growth.	Same	Rather more abundant than 15.

EXAMINATION OF FLIES.

Interesting as these results are, they do not really prove the point in question, the agency of flies in the dissemination of typhoid infection. They show, to be sure, that flies can take up typhoid bacilli from fresh cultures and then replant them a few minutes after on sterile culture medium, but it remained to be proven that flies having fed on mixed discharges, which have lain for some time in privy vaults, can subsequently crawl over various surfaces and yet finally deposit the living typhoid bacilli on foodstuffs at a considerable distance from the original place of infection. In order to do this, it would be necessary to catch the flies on the spot and make the bacteriologic examination without having subjected them to any artificial conditions.

3. Medical Record, 1898.

4. Brit. Med. Jour., Sept. 27, 1902.

Two places were selected in the neighborhood of Hull House as specially favorable for such an examination. The first was an unconnected privy on Polk street into which the discharges from two cases of typhoid fever were being thrown without any attempt at disinfection. The vault was either very shallow or very full, for the dejecta lay within three feet of the opening and had caught on the projecting scantling within a foot of the opening. The flies[5] caught within the vault, on the fence of the yard and inside the sick-room of one of the patients, which was also used as a kitchen, were dropped into test tubes containing culture medium and allowed to remain there for periods varying from fifteen minutes to twelve hours. Eight tubes were thus inoculated, three of which contained plain bouillon in which the flies were drowned, three the slightly acid gelatin-agar of Hiss and two the potato-water gelatin of Holz. In two of the bouillon tubes, the one from the sick-room and the one agar. From three of these tubes the typhoid bacillus was recovered; that is, from one bouillon tube inoculated with flies from the privy and from one bouillon and one agar tube inoculated with flies from the walls of the house and from the fence. From another bouillon tube with flies from the fence a bacillus was isolated belonging to the intermediate group above referred to, and another also of this group was isolated from one of the bouillon tubes which contained the typhoid bacillus.

At the time the collection was made there were no fresh typhoid discharges being emptied into this vault, so that the presence of living typhoid bacilli on the legs of the flies apparently proves either that the bacilli already in the vaults were living and multiplying, or that the discharges of the recovered cases still contained typhoid bacilli. In the Polk-street house the flies caught in the sick-room are especially interesting. This room was also used as the kitchen and at the time the collec-

from the yard, a bacillus was isolated which corresponds culturally with the typhoid bacillus, and which agglutinates in dilutions of 100 to 200 with the serum of immunized animals. In one of the tubes inoculated by flies from the vault a bacillus was isolated closely related to but not identical with the typhoid bacillus, belonging apparently to the group intermediate between the typhoid and colon groups.

The second place chosen was a yard on Aberdeen street containing one large, full and filthy vault, not connected with the sewer. This is used by sixteen families. Flies from the three privies built over this cesspool were used to inoculate two tubes of bouillon and one each of agar-gelatin and of potato-gelatin; other flies from the fence of the yard and from the walls of the two houses bounding the yard, at varying distances from the vault, were dropped into two tubes each of bouillon, gelatin and

5. In all cases the common house fly, *Musca domestica*.

tion was made the table was covered with food on which could be seen flies both living and dead.

The conditions found at these two places are repeated over and over again in this neighborhood, and when one considers that, in addition to the privies and defective plumbing, there are the sewer-infected back yards, that food is kept more or less exposed, not only in the houses, but in the groceries and fruit stands, that the houses are not furnished with screens, it can easily be seen what an important part the house fly may play in the spread of typhoid infection in such a neighborhood. It can also be seen that this is one factor which does not come into play to such an extent in more well-to-do parts of the city, where screens and good plumbing are the rule, or in newer parts of the city where the excrement is properly disposed of. There are, as was stated above, no available statistics as to the number of privies still in use in Chicago, but Dr. Reilly, assistant commissioner

of health, is of the opinion that more than half of them are within the Nineteenth Ward. It seems, therefore, not unwarranted to assume that the concentration of the typhoid fever in this particular quarter of the city during the late epidemic was due to the spread of the bacilli by flies from the undrained or imperfectly drained cesspools, the leaking closets and the infected earth of the yards.

BACTERIOLOGIC EXAMINATION OF THE FLY TUBES.

As already stated, the flies caught at the different places were dropped into six tubes of bouillon, six of potato-water gelatin and six of His' agar-gelatin. They were allowed to walk over the solid, slanted media, sometimes for fifteen to thirty minutes only, sometimes from one hour to twelve hours; others were drowned in the bouillon tubes. The flies were then removed with sterile forceps and the tubes set aside for twenty-four hours, the gelatin tubes at room temperature, the others in the incubator. All of the gelatin tubes liquefied in forty-eight hours to such an extent that they were useless. The agar tubes, with the exception of two in which the flies had remained not more than half an hour, were covered with a thick slimy growth, loopfuls of which were transferred to bouillon and the plating was done from the latter. The two in which the growth was not so abundant showed two or three black specks of excrement in each, and the colonies growing at these points were carefully examined, but yielded only sarcines.

The plating media used were the potato-water gelatin, the agar-gelatin of Hiss, and Lösener's .05 per cent. carbol-gelatin. Plates were made from the twelve tubes on all these media, and five of them were found so greatly contaminated as to be worthless. Sarcines, yellow, white and orange, liquefying protei, subtilis, megatherium, Zopfii, mesentericus and mycoides were all identified by their colonies, and the attempt to isolate the colon group from among them failed. Better success was obtained from the remaining five bouillon and two agar tubes. Two of them (A 1 and P 1) were so little contaminated with liquefying varieties that the original Holz plates remained usable until they dried. This medium was somewhat disappointing in the other cases, for the liquefying varieties often grew with apparently undiminished vigor, causing complete liquefaction by the time the typhoid colonies should begin to be characteristic. The carbol-gelatin was still less satisfactory, for the addition of .05 per cent. carbolic acid did not prevent the growth of the liquefying forms, but only retarded them; but it also retarded the growth of the typhoid colonies which often at the end of three days showed merely as clear droplets, not distinguishable from colon, or from a slowly liquefying motile bacillus. Moreover, the typhoid surface colonies never took the characteristic grape-leaf appearance, but were always round with smooth edges. On the whole, the agar-gelatin of Hiss gave the most satisfactory results. The tiny, greenish, bristly or thready colonies which developed in eighteen hours were easily distinguishable from the larger, brown, smooth-bordered colon colonies. The differences became more marked in forty-eight hours, for the typhoid colonies increased hardly at all in size, while the colon colonies grew much larger. The acidity of the medium retarded the growth of other forms.

Hiss[6] has recommended the transplantation of typhoid-like colonies to a semi-solid "tube medium" (containing glucose), in which, he claims, the typhoid bacillus is the only one causing a diffuse cloudiness without formation of gas, and in this way a rapid positive diagnosis can be made. In my experience this served very well to distinguish the typhoid bacillus from the colon and from various glucose-fermenting intermediate forms, but not from a non-sugar-fermenting bacillus which produces an early and persistent alkalinity in milk and which I have supposed to be identical with the *Bacillus fœcalis alkaligenes* of Petruschky. This bacillus caused a diffuse cloudiness in the tube medium, and inasmuch as it resembled the typhoid bacillus morphologically and in its growth on gelatin, agar and bouillon, it could be distinguished from the latter only by its rather more abundant brownish growth on potato and its failure to ferment any of the sugars or to cause even a transient acidity in milk or litmus whey.

Colonies of the colon bacillus were found on every plate, as was to be expected, and two organisms were isolated simply for purposes of comparison. Several intermediate forms were also isolated from the Hiss plates under the supposition that they were typical typhoid colonies, until the formation of gas in glucose media proved their nearer relation to the colon group.

The following is a diagram of the twelve organisms which were isolated from the fly tubes, and of a typhoid bacillus obtained in the laboratory of Rush Medical College from the blood of a typhoid patient and used as control. Those marked A were from the tubes inoculated at Aberdeen street; those marked P, from Polk street. The organisms A 3-c and P 3-b seem to belong to the group intermediate between the typhoid and colon bacilli, resembling the typhoid morphologically, in their growth on potato, gelatin and agar, and in their failure to ferment lactose or coagulate milk; resembling colon in the fermentation of glucose with formation of gas as well as acid, although not as abundantly as does colon. To this group belong the *B. enteritidis* of Gärtner, and the organisms isolated by Widal, Gwyn, Cushing, Schottmueller, Longcope, Hewlett, Johnston, Kurth, and recently Sion and Negel. There are minor variations in the growth of these organisms on culture media as they approach now the typhoid type, now the colon, but in the main the class is well defined.

P 3-b, with its dry, granular, brown growth on potato, early and persistent alkalinity in milk and litmus whey and its slight fermentation of glucose, corresponds closely with the bacillus isolated by Sion and Negel from the blood of five patients and from the well-water in a house epidemic of typhoid-like character. A 3-b and P 3-a ferment no sugars and produce an early and increasing alkalinity in milk and Petruschky's whey, and a relatively abundant growth on potato, characteristics which correspond to those of the *B. fœcalis alkaligenes* of Petruschky.

P 3-c and P 1-b are typical members of the colon group, except that P 3-c does not grow characteristically on potato. A 4 should, perhaps, be relegated to the intermediate group, but differs from all those reported, except one of Schottmueller's, in coagulating milk and forming a small amount of indol. It might be regarded as a feebly-growing organism of the colon group were it not for the failure to ferment lactose—the transient faint acidity is soon followed by a persistent alkalinity—and the production of a persistent alkalinity in milk and litmus whey.

The serum of an immunized rabbit was used to test the agglutinability of these organisms. The control agglutinated in a dilution of 1-200, not in a dilution of 1-400. All of the typhoid bacilli isolated from the fly tubes failed to agglutinate in dilutions of 1-400, two

6. Jour. Med. Research, 1902, vol. viii, No. 1, p. 148.

would agglutinate only in 1-100 dilution, and one in 1-150. P 3-b agglutinated in a dilution of 1-70, which is really greater than the dilutions used in the ordinary clinical application of the agglutination test, yet this organism proved by its growth in sugar media and milk to belong to the intermediate group. This agglutinability with typhoid immune serum on the part of an organism of the intermediate group has been observed several times (Durham, Klinger). Durham for this reason questions the value of the agglutination test as compared with cultural tests, for he has even found colon bacilli which agglutinated with this serum, as has also Klinger.

As all parts of the fly came in contact with the culture medium it is impossible to say that any one part was especially responsible for the conveyance of the bacilli. Firth and Horrocks were able to recover the bacillus from the head, wings, legs and body of the flies which had crawled over the typhoid cultures. The failure to isolate it from the excrement of the flies also agrees with the findings of Firth and Horrocks.

CONCLUSIONS.

1. The epidemic of typhoid fever in Chicago during July, August, September and October of 1902 was most severe in the Nineteenth Ward, which, with one-thirty-sixth of the city's population, had over one-seventh of all the deaths from this disease.

2. The concentration of the epidemic in this locality can not be explained by contamination of the drinking water, or of food, or on the ground of ignorance and poverty of the inhabitants, for the Nineteenth Ward does not differ in these respects from several other parts of the city.

3. An investigation of the sanitary conditions of this region shows that many of the street sewers are too small, and that only 48 per cent. of the houses have sanitary plumbing. Of the remaining 52 per cent. 7 per cent. have defective plumbing, 22 per cent. water closets with intermittent water supply, 11 per cent. have privies connected with the sewer but without water supply, and 12 per cent. have privies with no sewer connection.

4. The streets in which the sanitary arrangements are worst had the largest number of cases of typhoid fever during this epidemic, irrespective of the poverty of the inhabitants.

5. Flies caught in two undrained privies, on the fences of two yards, on the walls of two houses, and in the room of a typhoid patient were used to inoculate 18 tubes, and from 5 of these tubes the typhoid bacillus was isolated.

6. When the discharges from typhoid patients are left exposed in privies or yards, flies may be an important agent in the dissemination of the typhoid infection.

Results of Nephrectomy.—V. Carlier describes in *Echo Méd. du Nord*, vi., 49, the ultimate results in twelve cases treated by nephrectomy. The reflex irritation from the diseased kidney ceases with the extirpation of the organ, and it frequently happens that a patient afterward will tolerate drugs, mercury for instance, which caused serious disturbances before. The best results from the nephrectomy were attained in cases of renal tuberculosis derived from the blood. One of the patients contracted scarlet fever during convalescence, but the course of the intercurrent disease was normal, with no trace of albuminuria until the third week. In debating the question of intervention he is inclined to distrust patients whose urine contains an abnormal proportion of chlorids, either too little or an excess. A patient in the latter category died three months after a successful nephrectomy, from generalization of the tuberculous process.

PNEUMONIA: THE NEW "CAPTAIN OF THE MEN OF DEATH."

ITS INCREASING PREVALENCE AND THE NECESSITY OF METHODS FOR ITS RESTRICTION.*

ARTHUR R. REYNOLDS, M.D.
Commissioner of Health.
CHICAGO.

Figures are hard reading and harder hearing; but I must ask you to listen to a few in order that you may comprehend the magnitude of the pneumonia problem as I view it.

In the latest (1901) edition of his scholarly and most instructive "Principles and Practice of Medicine" Prof. William Osler, treating of pneumonia in the section of specific infectious diseases, says:

> The most widespread and fatal of all acute infectious diseases, pneumonia, is now the "Captain of the Men of Death," to use the phrase applied by John Bunyan to consumption.

He then adds:

> In the United States during the census year 1890 there died of it 76,496, a death rate per 100,000 of population of 186.94 [?]. In Chicago during the past ten years it has gradually replaced consumption as the principal cause of death, which A. R. Reynolds *attributes to the predisposing influence of Influenza.* In the last decade the death rate from pneumonia in Chicago was 18.03 per 10,000 of population, against 12.36 per 10,000 in the previous decade. There has been a marked increase in the disease in Baltimore, and Folsom has brought forward evidence to show that there has been a progressive increase in the death rate from pneumonia in the state of Massachusetts. The admission of pneumonia cases to hospitals during the past few years has, in some places, almost doubled.

These passages are cited for two purposes: First, that I may put their reader on his guard against the assumption that the great increase in pneumonia during the last ten or a dozen years is attributed by me solely "to the *predisposing influence of influenza.*" Second, that I may emphasize more fully than Professor Osler has done the extent of this increase, both in point of time and of proportion.

As to the first, it will probably be sufficient to call attention to the title of the paper on which the assumption was based. This paper appeared in the March, 1901, Bulletin of the Chicago Health Department, and was entitled "Influenza as a Factor of Recent Mortality"—not the only, but one factor. That influenza has been such a factor and a very important one since December, 1889, is now admitted by etiologists generally. That the increase of pneumonia mortality is due solely to its predisposing influence is disproved by the following figures of deaths from all causes, those from consumption and those from pneumonia during the last thirty years:

In 1880 the death rate from all causes was 14.59 per thousand of the total population of the country; in 1900 it was 13.67—a decrease of 6.3 per cent. in the general mortality rate during the twenty years.

The consumption death rate in 1880 was 18.21 per 10,000 of population and 12.46 per cent. of the total mortality; in 1900 these figures were 14.44 and 10.56 respectively—decreases of 20.7 per cent. in proportion to population and of 15.2 per cent. in proportion to total mortality.

* Read by invitation at the Sixth General Conference of Health Officials in Michigan, under the Auspices of the Michigan State Board of Health, Jan. 15, 1903, at Ann Arbor, Mich.

EDITORIAL NOTE.—See Editorial, "The Deadly Pneumococcus," in THE JOURNAL A. M. A., April 14, 1900, probably the first printed notice of the increasing importance of pneumonia as a factor in the mortality of recent years.

On the other hand, while the pneumonia death rate had decreased 3.26 per cent. in proportion to population it had increased 5.57 per cent. of total mortality between 1880 and 1890, and 11.0 per cent. in proportion to population and 12.21 per cent. of total mortality between 1890 and 1900. The increase began long before there was any influenza in the country.

These computations are made from the data in the summary of vital statistics in the Twelfth Federal Census—that for the census year 1900—and are for the whole United States. Similar computations for Chicago, and covering two additional decades, show more strikingly the great decrease in the general death rate and in the consumption rate, and the much greater increase in the pneumonia rate.

Based on the U. S. census figures of population for each year the following are the death rates per thousand population: In 1860, 20.73; in 1870, 23.88; in 1880, 20.79; in 1890, 19.87; in 1900, 14.68—a decrease of 29.1 per cent., or nearly one-third in the 1900 death rate from the 1860 rate.

The deaths from consumption per 10,000 of population were, in 1860, 25.28; in 1870, 17.68; in 1880, 16.95; in 1890, 17.93, and in 1900 they were 15.30—an aggregate decrease of 39.5 per cent. in the forty years.

From pneumonia the deaths per 10,000 of population in 1860 were 4.40; in 1870, 10.24; in 1880, 12.58; in 1890, 18.84; in 1900, 19.78—an aggregate increase of 349.6 per cent. of pneumonia as compared with an aggregate decrease of 39.5 per cent. of consumption.

Note that the increase of pneumonia between 1880 and 1890—when there had been no influenza in the country, except sporadic cases, for seventeen years, or since the epidemic of 1873—was 49.7 per cent., or from 12.58 in 1880 to 18.84 in 1890; while the increase between 1890 and 1900—the influenza decade—was less than 5 per cent. (4.9) or from 18.84 in 1890 to 19.78 in 1900. It is obvious that influenza, while it undoubtedly has been a potent factor in increasing the mortality rate from other diseases—such as those of the heart, kidneys and respiratory system—is not the sole, nor even the principal, cause of any recent increase of pneumonia.

Since the census year 1900 pneumonia has claimed more than one-eighth of all the victims of the Grisly Reaper in Chicago, one-third more than consumption and 44 per cent. more than all the other contagious and infectious diseases combined, including diphtheria, erysipelas, influenza, measles, puerperal fever, scarlet fever, smallpox, typhoid fever and whooping cough—the total of which deaths was 4,489, as compared with a total of 6,560 deaths from pneumonia.

WHAT MAY BE DONE TO CHECK THIS INCREASING PREPONDERANCE OF PNEUMONIA MORTALITY?

As chairman of the Section on Hygiene and Sanitary Science at the Fifty-third Annual Meeting (1902) of the American Medical Association, I made a special effort to secure attention to this problem, and among those who contributed papers on the subject were Dr. Edward F. Wells[1] of Chicago, who wrote on the fatality and increasing prevalence of pneumonia, with suggestions for individual and communal prophylaxis, and Dr. James J. Walsh[2] of New York City, on its incidence, mortality and prophylaxis. The paper read in the same section by Dr. Smith Ely Jelliffe of New York City, on "Influenza and the Nervous System," belongs with these papers—the advice therein given as to the prevention of this disease apply equally well to pneumonia. Dr. N. S. Davis,[3] Jr., of Chicago, also read a paper during the year, before the Illinois State Medical Society, on the treatment of pneumonia, in which was embodied some sound advice on prophylaxis.

From these papers I quote the following: Dr. Wells advises that for individual prophylaxis in a case of pneumonia the nasal, pharyngeal and oral cavities should be kept as free as possible from accumulations of mucus, and when it has been demonstrated that such secretions contain the pneumococcus such efforts should be especially well directed and maintained. In addition, care should be taken not to become chilled when overtired. The individual should, so far as practicable, keep out of the range of extruded pneumococcus-laden secretions of infected individuals. The sputum and other secretions of respiratory surfaces of pneumonic patients, or of other infected individuals, should be destroyed before they have been allowed to become dry. Such persons should cough and sneeze into a moistened cloth. He adds:

> There may be some comparatively simple means by which pneumonia may be prevented, but the fundamental information on which prophylactic rules may be formulated is not yet at hand; therefore, it should be the province and duty of public health officers to seek assiduously for such knowledge, and I would suggest that, as a preliminary step in this direction, pneumonia be placed on the list of notifiable diseases and that the environment of pneumonia patients be carefully noted and the results analyzed.

Dr. Walsh, after pointing out the contagious character of the disease, dwells on dust as a contagion carrier and urges the prophylaxis of clean streets, points out the danger of infection in crowded assemblies, and of defective house drainage and gas leakage as contributing causes. Specifically, as to preventive measures, he says:

> It would seem important, then, first of all to insure precaution against the spread of the disease by teaching the general public that there is always an element of contagion danger in a pneumonia case, and that certain protective and prophylactic measures are at least eminently advisable in order to avoid all danger. The secretions of pneumonia patients should be thoroughly sterilized by heat, or should be subjected to strong chemical antiseptics. The expectoration of pneumonia reeks with bacilli. It is often received into napkins or handkerchiefs, and must not be allowed to dry and find its way into the air, but must be carefully disposed of by those in attendance on the patient. Practically the same precautions as are now invariably [?] instituted with regard to tuberculosis should be suggested for pneumonia.
>
> Such directions will doubtless seem exaggeration of caution, not only to the general public, but to most medical men. Let us remember that the profession generally would have been quite as opposed to the suggestion of these precautions with regard to pulmonary tuberculosis twenty-five years ago. Now every one realizes that the old position in the matter was a serious mistake and founded on an erroneous opinion tenaciously held. The same thing may prove to be true of pneumonia.

Under the head of prophylaxis Dr. Davis says that:

> Never have physicians known so much of the nature of pneumonia or used remedial agents more intelligently than now. It is not their fault that the mortality of this disease is increasing. But is the medical profession altogether free from blame for its prevalence? Prophylactic measures have not been enforced as they should have been. It is well known that the cause of pneumonia is a micro-organism in the sputa of those suffering from the disease, and that the malady

1. THE JOURNAL A. M. A., Nov. 15, 1902, p. 1231.
2. Ibid., p. 1235.
3. Ibid., July 5, 1902, p. 1.

is engendered by inhaling it. Therefore, the same care should be taken to collect and destroy the sputa that is taken in pulmonary tuberculosis. It is not, however, a sufficient precaution to exercise this care during a patient's brief sickness, because the diplococcus of pneumonia is known sometimes to live and multiply for months and even years in the mouth, pharynx and nose of those who have had the disease. Therefore, during convalescence, and for at least two or three weeks thereafter, expectoration, if it occurs, should be into a sputa cup containing an antiseptic and water. Moreover, the patient's mouth should be rinsed several times daily with an antiseptic mouth wash. During the illness the greatest pains should be taken to prevent soiling bed clothing, carpets or furniture with the sputa. After the illness the patient's room should be thoroughly cleansed and ventilated. The enforcement of such measures will help to lessen the spread of this disease and will greatly lessen the frequency of its recurrence in those who have had it.

The facts that house epidemics are not infrequent and that the disease prevails, as other contagious and highly infectious ones do, in the winter season, when people are most crowded together and live much of the time in badly-ventilated apartments, suggests another prophylactic measure, which the public should be taught to apply, namely, thorough ventilation of houses, offices, factories, theaters, churches, cars and other public places, in order that the air which must be breathed may be kept clean and free from infectious matter.

Laymen should be taught not to be afraid of a patient who has pneumonia, influenza or tuberculosis, but to be afraid of lack of cleanliness about him during his illness, of failure to enforce prophylactic measures and of close, badly ventilated apartments during the season when these diseases prevail.

Although experiments with pneumonia serum have shown that a temporary immunity can be created in certain lower animals, it can not be in man. These experimental successes, however, lead us to hope for more certain means of preventing pneumonia than we now possess.

To these suggestions I would add that every precaution employed in a case of diphtheria should be enforced in a pneumonia case. The two diseases are much more similar from the prophylactic standpoint than are tuberculosis and pneumonia. The former are both acute; therefore, preventive measures are not necessary for so long a period as to become burdensome and perfunctory.

The organism which causes pneumonia may live in the tissues and air passages of human beings for a considerable time without producing the disease. Every person here present has doubtless had the germ in his tissues scores of times, and at this very moment it is in the bronchial tubes of many of us. But before pneumonia can develop in such persons some change must take place, either in the organism or in the individual. At present those of us who are acting as hosts to the germ of pneumonia do not get the disease because there is something in us that, for the time being, renders us immune. That something is to be found in every human body in normal health and vigor. The moment the vitality becomes lowered sufficiently from any of the many causes to which we are liable to become subject—and no one can measure the exact time or place—then the pneumonia organism begins to multiply, to feed on our substances and to give off a poison, and the result is pneumonia.

It may come to pass that a simple, direct method of preventing pneumonia will be discovered, but until that is done our efforts must be directed toward keeping our bodies in condition to resist and challenge the invasion of pneumonia. Whatever measures are taken to this end will apply with similar force to all other infectious diseases.

The element first in importance in keeping the health up to standard is pure air. Without air no one of us can live an hour, while we may live days without water and weeks without food. An important element in the increasing prevalence of pneumonia is, doubtless, the fact that more persons are spending their lives indoors than formerly—in shops, factories and offices. Sufficient air is only obtained by living as much as possible, both day and night, in the open air.

The air in dwellings, offices, factories and shops must be kept as pure within as without. If architects and builders can not secure proper air within buildings then we must to a greater extent in the future do away with buildings altogether.

Next in importance to pure air in dwellings is the necessity for sunlight. No room is fit to sleep in all night that has not been flooded with sunlight all day long. Human beings need the sun and the beneficial effect it has on the air they breathe quite as much as the vegetable kingdom needs it. The fashion of shades and shutters on windows will be abandoned as the beneficial effects of sunlight are understood.

Less need be said of the necessity for pure water and its constant use, both within the body and on its surface, for the world is now becoming awake to this fact.

With reference to food, no general rules can be laid down for all; but it is safe to say that the average adult person in the United States, who lives chiefly indoors, eats very much more than he requires to nourish his body; the extra amount is a burden on digestive power, clogs excretory organs and accounts for most of the malaise, headache and premature breaking down.

While pneumonia may be induced by the bad air, bad heating and bad lighting of dwellings, a more fruitful source of the disease is probably found in places of public assembly, such as schools, theaters, churches, street cars, etc. Greater attention must be paid in the future to the cleansing not only of the floors of such places, but of the air. What the American people seem to need is not more and better food, but more and better air. Overwork, overindulgence, excesses, all lower the vitality and render one a fit subject for pneumonia.

As to Dr. Davis' language concerning a pneumonia preventive serum, it may be remarked that it is barely ten years since the diphtheria antitoxin for both the prevention and the treatment of diphtheria was produced; that the anti-cholera and bubonic plague inoculations are of still more recent date; and that the scarlet-fever and whooping-cough sera are not yet two years old. Let us partake of the optimism of the apostle of bloodless surgery, Dr. Adolph Lorenz, who, in speaking of the probability of a successful serum treatment of cancer, recently said in his doctorate address[4] at the Northwestern University:

> If cancer is of parasitic origin, as one must hope, and as many of the most respected surgeons believe, then it may be possible that a curing antitoxin will be found. The prophecy of the great Joseph Lister, spoken as he gave his fellow beings antisepsis, will be appropriate for the second time: "Surgery will be quite different from what it has been heretofore."
>
> If this boon should come to mankind, then general surgery also will give way to a very little sharp but harmless instrument—the hypodermatic syringe.
>
> May the twentieth century give to the world, burdened with pain and death, this savior of mankind. The nation which gives birth to this genius will become the first nation of the world through this one deed.

It is not too much to hope that there is some one here present who may shortly give to the world the still more important boon of an antitoxin for pneumonia.

4. THE JOURNAL A. M. A., Jan. 10, 1903, p. 98.

Meantime, it remains for each of us—physician and sanitarian, curer and preventer alike—each in his appointed place, to do what in him lies to restrict the ravages of this, the most murderous modern scourge of civilized peoples. Let the physician instruct his pneumonia families as to the methods of saving other members of the household from falling victims. Let the sanitarian and the health officer push the propaganda of healthful living, the conservation and development of such inherited powers of vital resistance as the individual may possess—that vital resistance which is, after all, the best prophylactic against, not consumption only, nor pneumonia only, but against all the preventable diseases.

The work is not spectacular nor dramatic. It will have no such picturesque phrase as the "Great White Plague" with which to conjure and arouse sentiment and enthusiasm. There will be no imperial monarch to make it a fashionable fad by becoming the president of an anti-pneumonia league, nor will there be any royal palace set aside as a sanatorium for the treatment of pneumonia.

But in the end the persistent public educational work that shall restrict pneumonia will in like measure restrict all other diseases and so add to the span of human life.

ADDENDUM.

Note.—Since this paper was read before the conference the figures and computations have been revised to conform with the data of Table 1, Census Reports, Volume iv., Part 2, Twelfth Census of the United States. The original figures were taken from the Tenth and Eleventh Census Reports for 1880 and 1890 respectively, and the computations were made on those figures. Sundry discrepancies, noted in reading the paper, led to a comparison of the figures in the three several census reports, by which it was revealed that not only the figures of population but those of total deaths differ in the different reports.

For example: The population of the country in 1880 is given as 50,189,209 in the tenth census, and in 1890 as 63,069,756 in the eleventh census. In Table 1 of the twelfth census—above referred to—these figures are changed to 50,155,783 and 62,947,714 respectively. The total deaths are given as 756,893 for 1880 in the tenth census and as 732,017 in Table 1 of the twelfth census. Similar figures for 1890 are changed from 875,521 in the eleventh census to 841,419 in the twelfth census, Table 1.

The annual death rates per thousand of population, the ratio between these and the death rates from consumption and from pneumonia and the percentages of increase and decrease are, of course, affected by these changes. Not, however, unfavorably to the thesis of the paper—to-wit, that while the general death rate and the death rate from consumption have materially decreased during the last thirty years, the death rate from pneumonia had enormously increased during the same period.

Since the twelfth census is the latest and, presumably, the least inaccurate as to its statistical data, it has been thought well to revise the figures and computations in accordance therewith—the more so as the deduction of 24,876 deaths from the original 1880 figures and of 34,102 from the 1890 figures inspire the hope that in some future census the arbitrary addition of upward of 1,900 deaths to the actual number reported and recorded in the city of Chicago during the census year 1900, may also be deducted and the true death rate of the city for that period—15.08 per 1,000, instead of the erroneous census rate, 16.2—may be given.

Hope.—If we mingle with our hopes even a small modicum of judgment as to inevitable cause and effect, and if we also put forth an earnest effort to work for their realization, we can never be too hopeful. With this condition hope becomes a virtue to be cultivated, as well as a pleasure to be enjoyed. It is a wholesome tonic, a delicious draught. It not only cheers and consoles and encourages us by the way, but it gives strength to win the victory, or, if need be, to endure the defeat.—*Co-operation.*

Good for the State Board.—A new and most commendable step has been taken by the Ohio State Board of Medical Registration and Examination. Up to the present time the board, although having full discretion to revoke a physician's license to practice for such cause as immoral conduct, criminal offense or the abuse of intoxicants, has not exercised such discretion in criminal cases in which a conviction had not been obtained in court. In a recent instance in Columbus the board, very wisely it seems to us, after a full hearing voted to revoke the licenses of two physicians charged with attempting to produce a criminal abortion, and with being responsible for the subsequent death of the patient. [See THE JOURNAL, October 25, p. 1062, and November 22, p. 1329.] In these cases conviction in court is usually all but impossible, and very commonly the culprits escape with an acquittal or with no trial at all. Such seemed to be the probable termination of the case against the two men in Columbus, when the state board decided to take up the matter. Much genuine testimony was of course admitted that would have been ruled out of a court by those technicalities that so often are a shield for the guilty. In this case the young woman thought she was pregnant and charged a medical student with being the cause of her difficulty. The student enlisted the assistance of two physicians, who attempted to produce an abortion. As a matter of fact, as proved by the autopsy, the girl was not pregnant, but in their efforts the abortionists tore a hole through the uterine fundus, and then in trying to wash out the uterine cavity they injected a quart of water into the peritoneum. Death promptly resulted from general peritonitis. The testimony as to these facts appealed to the board as being conclusive, and the two physicians were stripped of their right to practice medicine. Every physician should applaud this action of the board and should at once extend to the board promise of every possible support in the admirable position that it has taken in this matter. No action more likely to deter men from performing criminal abortion could be suggested. Once it is known that the board intends to revoke the licenses of abortionists without waiting for the courts to find them guilty, the recreant physician who contemplates this crime will hesitate. From the clutches of the law he might escape on the slim technical rules of evidence, but this will not avail to preserve his certificate. Once his license has been revoked his only recourse will be to go into court as plaintiff against the board and prove himself innocent. This will be a much more difficult task than that of escaping the penalty of the law. Every physician should let the board know that its position is approved and will be sustained.—*Cleveland Med. Jour.*

Ignoring the New Until the Quacks Force it on Our Attention.—An eminently sound and conscientious practitioner tried in vain for 20 years or more to arouse the profession to a sense of the value of massage and mechanical therapeutics in the treatment of certain diseases. At last he gave up in despair. It was not just then fashionable. Editors would not accept his articles, and the lazy-minded, the exploiters of the popular opinion, beguiled themselves with the old-fashioned sneer at the "hobbies of hobby riders" and the world went on in its blind way. Then came the osteopaths and the biceps-worshipers of the cheap magazines, and what the profession would not listen to from its own members was, willy nilly, forced on the attention by the quack. It is true that other regulars and scientists prior to the quack knew all and far more than he of the value of massage, but, like so much other knowledge, it was not realized in daily practice by the leaders and by the masses of the profession. It required the compulsion of ignorant popular enthusiasm to make us actually treat our patients by these methods and to put into use the partial veritable truth turned into an untruth by the extremism and indiscrimination of the charlatan. But why need we carry out, generation after generation, this stupid belittling and ignoring of the new truth? There are many such illustrations as the one we have cited, of our strange indifference to methods of treatment, 10, 20 or 30 years after demonstration has been made of their efficacy and value. Let us keep our minds open and flexible!—*Amer. Med.*

PROTEID METABOLISM.

At the present time physiologic chemists are looking for the greatest advance in knowledge of intracellular metabolism to come from the many recent observations on the intracellular ferments. As has already been noted in these columns, the fundamental observations on proteid splitting enzymes in the tissue cells were made by Salkowski and his pupils, who showed that tissues of all kinds are able to digest themselves when kept at incubator temperature for a time, in the absence of bacteria. This process of autolysis is due to the presence, within the cells, of an enzyme which is very similar to the trypsin of pancreatic juice, although not identical, as is shown by careful study of the products of the digestion.

A most important advance seems to have been made recently by Martin Jacoby,[1] who has obtained evidence that the ferments that accomplish autolysis are to a certain extent specific, that is, extracts of one organ will not digest the tissues of a different organ. The importance of this observation lies in its agreement with the more modern ideas of proteid metabolism, which hereby receive much support. There seems to be good evidence that fats and carbohydrates are taken into cells in a diffusible form, and are then built into the less labile constituents of the cell, undergoing again splitting before they are either used or transported to other cells. For example, sugar is synthesized into glycogen, and then broken into sugar molecules; fat is synthesized in the cell from the alcohol and fatty acid that compose it, but is again split into these components before it can be further used or carried away. But the proteids present a much more complex problem, since they are of many kinds, seemingly different in each cell or tissue, and since their splitting products are many and far more complex than those from fats and carbohydrates. Jacoby considers that since the proteolytic enzymes of the cells will split only the proteids of the same kinds of cells, it is strongly suggestive that likewise when their action is reversed they will build up only the specific substances of the cells from the heterogeneous materials brought to them from the blood.

This theory needed evidence that the body cells can build up non-proteid products of proteid digestion into tissue proteids, and a paper furnishing this evidence has appeared almost synchronously with Jacoby's article. It is a pretty well-known fact that the soluble albumoses and peptones are not absorbed as such from the intestinal tract, and the teaching has been that they are in some mysterious manner transformed during their passage through the intestinal wall, since they are not found in the blood coming from the intestines, at least not in any amount comparable to the quantity absorbed. It was generally supposed that the diffusible digested proteids were converted into the proteids of the serum, to be used later in the cells in some unknown way. Not long ago Cohnheim showed that the intestinal epithelium contains and secretes an active enzyme, *erepsin,* that has the property of splitting albumoses and peptones into the simpler, non-proteid bodies, although quite unable to attack undigested proteids. This made it seem very probable that the albumoses and peptones do not appear in the blood coming from the intestines because they are further split by the erepsin. In other words, the formation of albumoses (or better, proteoses) and peptones is not the chief purpose of proteid digestion, but these bodies appear merely as intermediary products. If this is true then the cells of the body must be able to form these ultimate splitting products into the proper tissue proteids.

O. Löwi[2] took up this question and found the hypothesis correct, according to the results of his experiments. He permitted pancreas to digest itself until no reaction for proteid could be obtained, and then substituted it for proteid in the diet of a dog that was in nitrogenous equilibrium. It was found that it took the place of the proteid completely, for nitrogenous equilibrium was maintained, and therefore the simpler nitrogenous bodies must have been synthesized by the body cells to repair the continuous loss of cell proteid.

While these experiments are few in number and awaiting confirmation, they agree so completely with theoretical expectations that they are of the highest significance. Surely the demonstration of synthesis of the proteid molecule from simpler bodies, most of which are well known both as to properties and structure, lets much light into one of the deepest biologic mysteries.

THE SIGNIFICANCE OF ALBUMINURIA.

At the last meeting (Jan. 19, 1903) of the New York State Medical Association, New York County Branch, there was an interesting discussion of the significance of albumin in the urine, which was opened by the medical director of one of the large life insurance companies. As life insurance examiners have more extensive opportunities and especially opportunity for more prolonged observation in this subject than practitioners generally and as their judgment in the matter is responsible to the financial department of the company, their conclusions and suggestions can scarcely fail to be of practical value. Dr. Edward Lambert considers that for length of life the habits of the individual, his customs, especially with regard to highly spiced food, al-

cohol and tobacco, and the intensity of his application to business, with the time given to sleep, are factors of much more significance than the presence of a small amount of albumin. Very few young men pass a whole year without the occasional appearance of albumin in the urine, the result of overexercise, or of extremes of heat and cold. If this passes away in a short time it has no special prognostic significance, even though it may be accompanied by a few casts. But if it continues to be present the irritative conditions to which it is due may eventually cause, if it has not already, true kidney degeneration.

The amount of danger in any case is not proportionate to the amount of albumin in the urine. Dr. Lambert recalled a case in which so slight a trace of albumin was present that it could be detected with assurance only in a favorable light after careful filtration of the urine. It was decided that so slight an albuminuria could only be physiologic. Accordingly a policy was issued which matured by death within two years, though the business partner of this same applicant, who was at the same time absolutely refused because of the presence of a notable quantity of albumin, survived for more than twenty years. In one case albumin could be detected only in the afternoon urine. It was never seen in the morning urine, so that the family practitioner insisted on the absence of any significance. The patient died of chronic nephritis, however, within five years.

Osler,[1] in a recent article, referred to a number of patients who, in his experience, had lived for many years after their rejection by insurance companies because of albuminuria. Such selected cases represent actually, however, only a very small proportion of the whole number of the rejected. The presence of albumin always means that something is wrong. With care patients may live for many years, despite its presence, but no better stimulant to the adoption of a more healthful mode of life could be given them than refusal by an insurance company. Many a man owes prolonged life to this circumstance, and family practitioners should realize this influence for good and take advantage of it, rather than lessen its force by protestation against it, as is so frequently the case.

Dr. S. O. Vanderpoel, in discussing Dr. Lambert's paper, said that undoubtedly many applicants refused fifteen to twenty years ago by insurance companies because of the presence of albumin in the urine are still alive. A careful collation of the statistics of such cases, however, shows that from four to five times as many of these rejected applicants are dead as ought to be according to the normal expectation of life among men of their years. Albuminuric individuals very seldom live out more than one-half of their expectation of life, and if any serious illness intervenes it is almost sure to carry them off. Hence the necessity for the elimination of these cases from among the ordinary risks assumed.

1. "On the Advantages of a Trace of Albumin and a Few Tube Casts in the Urine of Certain Men Above Fifty Years of Age." N. Y. Med. Jour., Nov. 23, 1901.

The full significance, then, of albuminuria, even when accompanied by urinary casts, is not known as yet. We are almost entirely in the dark as to the meaning of nucleo-albumin, which would seem at times to be serious, since it has been found associated with eclampsia. It is to be hoped that careful investigations of such cases and observation of the conditions for many years will eventually give us the exact knowledge we now lack. There is no doubt of the importance of the subject, the field is most promising and the opportunity for good work of enduring character is open practically to every painstaking practitioner.

THE TREATMENT OF DUPUYTREN'S CONTRACTION.

The treatment of few, if any, of what may be termed minor surgical affections has been attended with such difficulties as that of Dupuytren's contraction. The clinical picture of this obstinate condition is sufficiently well known to all engaged in surgical dispensary practice. Gradually and without pain the fingers of one of the hands is drawn downward toward the palm, the contracture progressing gradually until several fingers, possibly the entire hand, is almost entirely useless. The ring finger of the right hand is generally first affected, and as the disease advances the little finger and middle finger are also affected. The thumb and index finger are seldom involved. All the structures of the flexor surface of the hand, muscles, tendon and skin have been considered possible factors in the production of this condition, but Dupuytren, after long observation and careful study of the tissues, was the first to show definitely that the seat of the disease is in the palmar aponeurosis, and this has been thoroughly established by repeated subsequent observers. Examination of tissues removed shows that the process is one of chronic hyperplastic inflammation with scar tissue contraction. As the process progresses not only the aponeurosis, but frequently also the skin, the ligaments and joints themselves are involved. The course of the disease is extremely chronic, from three to ten years being required before the contracture is complete.

The difficulties of treatment have been all the greater because so little is known as to its etiology. Injuries of the palmar fascia, particularly by those who use the tools of some trade continuously, rheumatic affections, general sclerosis and nervous origin have all been suggested as possible causes; however, constitutional treatment has proved of little avail in these cases. Malgaigne and some of the earlier surgeons, believing that the contracture was primary in the muscles, resorted to division of the tendons, thus producing a state of affairs worse than before. Sir Astley Cooper advised the more rational procedure of dissecting out the contracted tissue with temporary or permanent cure in some cases. Others have simply divided the contracted aponeurosis and skin and straightened the fingers forcibly, but this has been usually followed by recurrence. Electrolysis

and various forms of apparatus for extension have also been tried.

The latest suggestion as to treatment comes from the clinic of Von Bergmann of Berlin.[1] Lexer, one of Von Bergmann's assistants, has treated eight cases by removal of the entire aponeurosis and overlying skin and covering in the defect with a flap with a pedicle from the chest wall or by a flap taken from the thigh. The results in his cases, after two and a half years' observation, were very satisfactory except in two cases, in which there was keloid formation requiring a second operation. Many of the earlier methods of treatment have given fairly satisfactory results, and might perhaps be advised before resorting to such radical measures, but for recurrent and obstinate cases this procedure seems to be a reasonable and justifiable one.

IMAGINARY BRIGHT'S DISEASE PRODUCED BY QUACK ADVERTISEMENTS.

The following clipping is taken from a recent daily paper:

SUICIDE DUE TO CAUSELESS FEAR.

Andrew J. Teggin, an artist, whose pictures have been exhibited at the Academy of Design, took chloroform to-day and died soon afterward at the New York Hospital. Teggin's death was the end of five years' dread of Bright's disease. Though eminent specialists had assured him he had no symptoms of the disease, he persisted in believing that he was doomed to die from it, and this so worked on his mind that he killed himself rather than wait for the end he felt sure would come.

No statement of the case of the man's morbid psychology is mentioned, but the following passage published prominently in another portion of the same paper is highly suggestive:

TEST YOUR KIDNEYS.

Let some morning urine stand for twenty-four hours in a glass, or bottle. If then it is milky or cloudy or contains a reddish brick-dust sediment, or if particles or germs float about in it, your kidneys are diseased.

Could anything be more fiendishly deceptive? The fact that the "remedy" that this advertisement proclaims has been on the market for many years, and that, to our knowledge, this particular trap has been laid for some years, indicates that there must have been many victims. Imagine the horror that must fill the mind of the poor fellow who views a cloud of phosphates or bacteria, which can hardly fail to be present in the urine left in a "glass or bottle," as he appreciates that he is in the clutches of the dread Bright's disease; for does he not know that this is as surely fatal as is cancer or consumption. And if, because of winter's cold, no bacterial development occurs, and the urine remains clear, does he escape? Not if the advertiser knows it! For in that event there is provided the alternative of "a reddish brick-dust sediment" of uric acid coming down in the acid urine.

What must be the sum total of the secret worry, the growing fear, the startling terror at every mention of the death of some one from Bright's disease, among the many who have been deluded by this simple advice to "test your kidneys." If we did not know the mental attitude of the charlatan, far more heartless than that of gambler, swindler or other criminal who defrauds by means that do not rest on the victim's very hope of life and health, we could not believe that he appreciated the results of his insidiously worded lures. But he does fully; every mail brings him letters full of the terror of the fatally ill, the hope of the dying, the last clutch at the straw, and all these are cheerfully turned to profit. Weir Mitchell, in "The Autobiography of a Quack," has accomplished the remarkable feat of depicting a character without one spark of humanity, without a quality that might give one hope of some hidden redeeming grace—and such a character must be necessary for the hero of such a tale.

1. Janssen: Arch. f. klin. Chirurgie, 1902, vol. lxvii.

DEATH OF DR. W. E. B. DAVIS.

As we go to press the sad news reaches us by telegram of the death from accident of Dr. W. E. B. Davis of Alabama. There could be hardly any death that would more shock the profession generally than his, cut off in his early prime with an enviable record behind him and every promise of greater usefulness and distinction in the future. There are few, if any, who had more than he the faculty of winning friendship and holding it; his personality was a most strikingly gracious one and of the very best type of southern gentleman. The official positions of honor, trust and responsibility to which he was called indicate the appreciation given to his abilities and personal qualities, both by his associates in his particular specialty and by his professional brethren generally. It is customary to say nothing but good of the dead, but in this case there are no mental reservations, nothing else could be said.

THE ITHACA TYPHOID EPIDEMIC.

With all our progress in hygiene and sanitation we have occasional examples of how things ought not to be in this particular line. According to the press reports such an instance is very strikingly given in the condition of Ithaca, N. Y., at the present time.[1] The case is the more notable in that the town is the seat of one of our largest universities where lack of information as to up-to-date sanitation can hardly be presumed to exist. The university, of course, does not have the town sanitation under its charge, but the town authorities can reasonably be assumed to have had ample chances of enlightenment on such matters. Where they seem to have been blameworthy is in not sufficiently guarding the sources of their water supply, which has apparently been proven to be the cause of the present outbreak of typhoid in the town. The alleged fact that the university itself is a large stockholder in the water company supplying the polluted water is also a serious indictment against its authorities; it is unfortunate—to say the least—if it has been even a passive agency in the spread of the disease. It is charged by the newspapers, moreover, that their negligence was not altogether passive; that the executive authorities of the institution were requested by the senior class that meas-

1. The Journal, under New York News, Feb. 7, 14, 21 and 28.

ures should be taken to supply uninfected water and the request was refused. If these allegations are true the aspect of the case is more serious. We hope there is some mistake as to the facts. While the charges do not necessarily imply moral obliquity or intentional and deliberate recklessness as to human life, the alleged neglect and oversight is of the class of blunders that are, as Napoleon said, sometimes worse than crimes. It will be a lesson to authorities and trustees of institutions who fail to appreciate their responsibilities.

SUBSTITUTION AND ADULTERATION.

The recent utterances of the New York health commissioner showing the adulteration in the pharmaceutical retail drug trade, and still later remarks of the chemist of the Agricultural department to the New York Society of Medical Jurisprudence, alike indicate the existence of an evil that especially affects the medical practitioner.[1] If we can not depend on the dispenser for pure articles in our prescriptions the administration of medicine is a farce, and we had better go back to the old saddle bag or the more modern buggy case. If reputable drug stores, such as are many of the 300 from which the samples were obtained by the New York health commissioner, can not be relied on, the situation would seem to be discouraging. We can not lay everything to the retailers, however; they are themselves often victims and the matter needs further investigation. The foundation of a government drug laboratory, which would keep track of the standard preparations and check adulteration, would be a boon not only to the medical profession, but to its patrons. Of course, the manufacturers of the adulterated proprietary drugs make the most of it, but to a certain extent the high prices placed on their preparations which would otherwise be more readily available give them a certain responsibility for the evil. We hope the investigation will not be dropped until the evil practice is ended.

DICHOTOMY, OR THE DIVISION OF FEES.

It seems that the evil of commissions and division of fees is not confined to this country. They have it abroad, in Belgium, for example, where it has recently been brought before the Council of the College of Physicians, though they give it a name which seems a little pedantic. They call it dichotomy, perhaps with the idea of making it less likely to attract public attention. Here we are not so careful as we might be in this regard. Whatever scandal we have is made public from its beginning—to some extent to our disadvantage. The official decree promulgated by the Council is that a physician may not charge a commission of a surgeon to whom he sends a case and no surgeon may allow such a fee. The attending physician may only charge for his own work and his assistance that he has given in the surgical operation. Of course, this decree is favorably commented on by such foreign journals as have noticed it. They point out that a patient feeling himself the victim of a double charge will have less confidence, not only in his medical attendant, but in others in the transaction, and not only his attendant, but the whole medical body will suffer in prestige. It would seem that this particular point might be made a little more prominent in our medico-ethical codes. It is interesting, however, to know that trouble with this problem is common on the other side of the Atlantic. There is a sort of sinful satisfaction in knowing that our countrymen are not the only sinners.

1. See THE JOURNAL, Feb. 21, 1903, p. 525.

Medical News.

MARYLAND.

State Care of Insane.—In the recent annual report of the lunacy commissioner of Maryland state care of the insane is urged. "Already 5 or 6 counties send all their insane to the state institutions and many other counties care only for a few demented cases. The time is ripe for a radical change from county to state care. . . . Spring Grove and Springfield hospitals are models of their kind, the former adapted to the care of the more acute cases, the latter for chronic cases. It is to be regretted that Bayview, the city asylum, is not dispensed with. It is manifestly improper to attempt to care for the city paupers and the city insane under the same management. Either the city should maintain a separate asylum for its insane, apart from the almshouse, or what would be far better, acquiesce in the plan of state care. If the two state hospitals, Spring Grove and Springfield, were enlarged, the insane of the state could be cared for in a far better manner and really at lower cost than under the present system." Discussing the increase of alcoholism and the use of drugs as promoting insanity, the report continues: "Recent enactments by the legislature make it possible for such persons to be committed for a period, under the jurisdiction of our courts, and it would work great good if this provision of the law was oftener availed of. It is perfectly feasible to have at Springfield a colony of inebriates, committed for a definite period, who could be recommitted on the first offense after leaving the colony. An incalculable amount of good might be accomplished by this system."

Baltimore.

Personal.—Dr. William Howell, dean of the Johns Hopkins Medical School, was the guest of honor, February 21, at the annual banquet of the New England Alumni of the Johns Hopkins University, held at Boston.——Dr. 1. H. Elderice broke his knee-cap in attempting to board a street car February 19.

Abortionist Convicted.—Dr. William B. Hawkins, who forfeited bail and was arrested in Philadelphia, was convicted in the criminal court February 19, of manslaughter, in causing the death of a young woman here in November, 1901, by criminal operation. The penalty ranges from nominal fine or imprisonment to ten years in the penitentiary. It was the second trial, the jury disagreeing at the first trial, last October. Motion for new trial was made.

Health Report.—There was a still further decrease in the number of cases of measles reported last week, the number being 86. With this decrease the death-rate between the whites and blacks assumed its normal proportion, about 1 to 2. Whether this is a mere coincidence is unknown. There were 34 deaths from pneumonia, 6 from measles and 11 from la grippe. One case of smallpox was reported in a sailor who is supposed to have contracted it down the bay.

Hobbies Help College.—The late Dr. William H. Crim had two hobbies, the Fifth Maryland Regiment, of which he was for many years surgeon, and his extensive and valuable collection of antiques. Many of these antiques are of interest on account of their association with royal personages or with distinguished citizens, as Washington, Lafayette, etc. His widow has just died and in her will she has made large reversionary bequests to the University of Maryland School of Medicine, for the establishment of a professorship and scholarships for poor young men studying medicine. The struggles which her husband made to acquire his professional education led her to think that she could not make a more worthy disposal of his property or more suitably perpetuate his memory, than by providing for similar cases. The amount which will be available is at present uncertain, as it depends on the result of the sale of the collection, which represents Dr. Crim's entire fortune, as he left no real estate nor life insurance. It will probably be taken to New York, where it will bring a

large price, possibly $100,000 to $200,000. The will provides a trust by which four persons, relatives of Dr. and Mrs. Crim, are to receive the benefit of the estate during life, and on their death the whole estate, except $25,000 which is specifically bequeathed, is to pass to the University. One of the specific bequests is $5,000 to Dr. John G. Jay, Dr. Crim's physician.

NEW YORK.

Donation to Hospital.—Mrs. Charles D. Vail has given $6,000 to the City Hospital, Geneva, to finish and furnish the wings now being erected.

Demand Registration of Nurses.—Several hundred physicians and citizens of Buffalo and Rochester have signed a petition favoring the bill demanding registration of trained nurses to be introduced at Albany this week. The bill is designed to shut out incompetent nurses and provides for extended training before registration.

To Render Immediate Aid.—The New York Central Railroad has perfected a hospital and medical system. Contracts have been made with hospitals and physicians in all cities and towns of any prominence along the line of the road. The new system has been adopted so that immediate medical service may be rendered in case of train wrecks or other accidents to employes or passengers.

The Ithaca Epidemic.—The State Commissioner of Health, Dr. Daniel Lewis, New York, visited Ithaca, February 24, to investigate the typhoid fever situation. He found that contaminated water was the specific cause of the epidemic, and expressed his belief that the epidemic was on the wane, as less than one hundred serious cases then existed in the city. He believed, also, that the highest mortality rate had been reached and that the mortality of the epidemic throughout had been relatively low.

Coroner's Office Recommendations.—A committee of the New York County Medical Association, consisting of Drs. Stephen Smith, E. Eliot Harris and Harry R. Purdy, presented to the association a report containing the following recommendations:

1. The duties of investigating sudden deaths should be transferred from the coroner to the health department. 2. The present legal duties of the coroner should be turned over to the district attorney's office. 3. The judicial duties of the inquest should go to the magistrate's court. 4. Duties, other than those pertaining to the inquiry into the cause of death and the inquest, should go to the city chamberlain.

The report was referred to the committee on legislation, with instructions to endeavor to secure the legislation necessary for carrying into effect the recommendations contained in this report.

Buffalo.

Personal.—Dr. Devillo W. Harrington and Dr. Charles McCarthy are spending a vacation in Mexico.——Dr. Charles Van Bergen, Buffalo, will spend the summer abroad.——Dr. Earl P. Lothrop has gone to Florida.——Dr. Edward J. Meyer is taking a southern trip.

January Mortality.—The monthly report of the department of health for January shows an annual death rate of 14.3 per 1,000. Among the principal causes of death are pulmonary consumption, 42; typhoid fever, 16; debility, 32; cancers, 21; apoplexy, 26; meningitis, 13; valvular heart disease, 20; pneumonia, 53; nephritis, 19, and violence, 17. The total deaths for January were 441, as compared with 381 in January, 1902.

Marine-Hospital Commission.—The commission appointed by the government to select a site for the proposed marine-hospital in Buffalo has arrived. It is composed of Surgeon Louis A. Williams, U. S. Marine-Hospital Service, and Mr. F. B. Wheaton, of the supervising architect's office. They are under orders from the Secretary of the Treasury and are to report to him at the conclusion of their investigations.——Congress appropriated $125,000 for a marine hospital at Buffalo and the act provided that not more than $25,000 should be spent on a site.

University Day.—University Day exercises were celebrated by the medical department of the University of Buffalo, February 23. The public exercises took place at the Star Theater, where Prof. Herbert L. Willett of the University of Chicago delivered the address. In the afternoon a reception was given to the senior and junior students and the faculty at the home of the dean of the medical department, Dr. Matthew D. Mann. In the evening a reception was tendered at the college building by the alumni association.

New York City.

Personal.—Dr. St. Clair McKelway, Brooklyn, a life member of the State Board of Regents, has resigned on account of failing health and numerous other demands on his time.

German Hospital Report.—The annual report of this hospital shows that in the year 1902, 3,247 patients were admitted, of whom 2,632 were non-paying. The average daily number of patients was 176.

Druggists Arrested.—According to the chemist of the health department, 40 out of 215 druggists were found to be selling Jamaica ginger and aromatic spirits of ammonia adulterated with wood alcohol. Some of these druggists have been arrested in consequence.

Grip and Pneumonia Prevalent.—According to the records of the health department there has been a rapid increase in the number of cases of influenza, though the disease is of a mild type. In the past three weeks the deaths from pneumonia were 155, 210 and 190 respectively.

Hospitals Under Financial Stress.—The serious financial situation that confronts the New York hospitals has led George MacCulloch Miller, president of the Saturday and Sunday Association, to make an urgent appeal for generous gifts in behalf of the 40 institutions in the association.

Disregard of Diphtheria Antitoxin.— Dr. J. H. Raymond of the health department complains of the unnecessarily high death rate from diphtheria in the Borough of Brooklyn, i. e., 18 per cent., and maintains that if diphtheria antitoxin were more promptly and generally employed, this death rate would not be over 7 per cent.

The Aronson Serum Tried.—The first trial in this city of the new serum for scarlet fever has been made by Dr. Louis Fischer. The serum used was that discovered by Dr. Hans Aronson of Berlin, and with which experiments have been made by Dr. Adolf Baginsky since last summer. Dr. Fischer reports that although his case of scarlet fever was severe a prompt amelioration of all the signs and symptoms followed the use of the serum.

Substitution Enjoined.—At a special term of the Supreme Court a final decree was entered in the case of Fairchild Brothers and Foster vs. John H. Everhardt et al., whereby the defendants are enjoined from dispensing any essence of pepsin or preparation not manufactured by the plaintiff, in imitation of, or in substitution for, Fairchild's essence of pepsin, whenever Fairchild's product is asked for. Damage to the amount of $250 and costs of $42.72 were assessed on the defendants.

PENNSYLVANIA.

Sewer Suit.—Martin G. Peifer and wife have sued the city of Lancaster for $10,000 damages, alleging that owing to the flooding of a cellar by a sewer several cases of typhoid fever were caused in the family.

Smallpox Closes School.—The students of the Edinboro State Normal School, several hundred in number, have all left the institution and gone to their several homes because of the presence of smallpox in the town.

Hospital Room Endowed.—The Columbia Hospital, Columbia, has received from the widow and children of the late H. H. Houston of Philadelphia, a gift of $5,000 for endowing a room to be called the "Houston Memorial Room."

Wholesale Vaccination.—The H. C. Frick Coke Company has issued an order that all of its employes and their families be vaccinated. It is said that fifty physicians have been engaged for the work and that $10,000 worth of vaccine virus has been purchased for the vaccination of the 300,000 individuals affected by this order.

To Abolish Secret Remedies.—A bill has been introduced into the legislature providing that proprietary and patent medicines shall bear on the label a copy of the formula, including the several ingredients and the quantities of each. The bill provides, also, that none but a regular graduate of pharmacy properly registered under the laws of the state may prepare such medicine. Violation of the act renders one liable to a fine of $1,000 and imprisonment for one year, or both, one half the fine to go to the informer.

Urge Stringent Regulations.—Dr. Hugh Hamilton, Harrisburg, on behalf of the Dauphin County Medical Society, has presented a memorial to the committee on judiciary general of the house of representatives, urging the passage of the "act to establish a medical council," which has been referred to in THE JOURNAL. They say, in part:

There is need for a general law requiring every one who claims to heal or treat the critically ill, the trusting sick or gullible ailing

public, to be examined by the medical council. Without such a law it would be a manifest wrong to permit the collection of money for incompetent work, whether the "tort" or fraud was intentional or not.

Sanatoria for Poor Consumptives.—A bill has been introduced into the legislature providing an appropriation of $500,000 for the erection of two sanatoria for poor consumptives. The institutions are to be similar, one to be located in the Pocono Mountains, the other probably at Mont Alto. The institutions are to be so constructed as ultimately to accommodate at least 2,500 patients each. The state forestry reservations are to provide the sites. The governor is authorized to appoint a commission of five to be known as "The Pennsylvania State Tuberculosis Commission," and this commission is to select the sites, construct the buildings, and administer the institutions.

Philadelphia.

Alleged Physician Arrested.—F. D. Clark, who claims to be a physician, is held by the police awaiting the result of an illness said to be due to an illegal operation performed by him five days before on a young girl who was brought to the Jewish Hospital suffering from peritonitis.

University Day.—On the occasion of "University Day" celebration, February 21, by the University of Pennsylvania, Dr. S. Weir Mitchell delivered an address on "George Washington in His Letters." Brigadier-General Leonard Wood, M.D., U. S. Army, was one of five to receive the honorary degree of doctor of laws.

Medical Appointments in National Guard.—Among new appointments made by the governor are those of Dr. Robert G. LeConte as surgeon-general to succeed Dr. John V. Shoemaker; Dr. George M. Coates, surgeon of the Second Regiment, with the rank of major, and Dr. Ross H. Skillern, assistant surgeon, with the rank of first lieutenant and assigned to the same regiment.

Typhoid, Smallpox and Deaths.—The epidemic of typhoid fever is gradually abating. Smallpox continues to prevail to an extent to cause uneasiness among the health officials. During the week ended February 21, 25 new cases of smallpox were reported and 6 deaths from the disease. During the same week there were 582 deaths from all causes. The extreme cold weather is considered partially accountable for the increased death rate.

A Deserved Honor.—Dr. Simon Flexner, professor of pathology at the University of Pennsylvania, has been chosen as chief of staff of the Rockefeller Institute for Medical Research, to be located in New York. Dr. Flexner gained especial distinction by his work on "The Etiology of Dysentery" and "Snake Venoms." He was a member of the commission sent to the Philippines by the Johns Hopkins University to study diseases peculiar to those islands.

Contract for Hospital Awarded.—The contract for building the new Municipal Hospital has recently been awarded at $143,210. It is to be built on the new site in the Thirty-third Ward, and is to be completed in 190 working days. The structure is to be a colonial building, 200 feet in length by 150 feet in depth. For smallpox patients there will be two large wards, each 150 by 35 feet; several smaller wards will be constructed for patients with other contagious diseases. An ordinance is pending to sell the present Municipal Hospital and grounds.

GENERAL.

Manila Cholera Report.—Manila is free from cholera, and Santiago Cholera Hospital has been abandoned. If any cholera sufferers are found in Manila in the future they will be cared for at San Lazaro Hospital. Santiago Cholera Hospital was opened March 27, 1902, and up to Jan. 1, 1903, cared for 1,268 cases of cholera. The average mortality was 65.28 per cent. The Americans cared for numbered 146, the mortality among them being 32.87 per cent. Dr. Lindley, who has been in charge, has done very faithful and efficient work.

Whiting Still at Large.—Despite the notices which have already appeared in THE JOURNAL warning the medical public against F. Whiting, who represents himself as an accredited agent of the American Medical Association, and of THE JOURNAL, he is still at large and pursuing his fraudulent way through the East. During the last week we have received advices that this individual has been operating in Greene, N. Y., and Bath, Pa. The police authorities of Reading are on his track, and any information sent to the Chief of Police, Reading, Pa., or to THE JOURNAL will be appreciated.

CANADA.

Proposed Infirmary for Victoria, B. C.—A meeting was held recently in Victoria by those interested in establishing an infirmary in that city, in connection with the isolation hospital.

Typhoid Outbreak Among Nurses.—Five nurses of the Royal Victoria Hospital, Montreal, are convalescing from typhoid fever. Five years ago there was a similar epidemic. The authorities have found nothing at fault in the sanitary arrangements of the hospital.

McGill Graduates in British Columbia.—At the annual meeting of the British Columbia graduates of McGill University, held February 14, Dr. D. H. Harrison, the oldest graduate in that province (1864), was elected to the presidency. It was decided to continue the $50 prize to the best B. C. matriculant each year to McGill, and $25 to the second best. Dr. McGregor, Vancouver, founder of the society, was re-elected secretary; Dr. Tunstall, Vancouver, treasurer, and Dr. G. H. Manchester, New Westminster, one of the vice-presidents.

A Hygienic Institute for the Western University, London.—A deputation, headed by Dr. Robert Ferguson and Dr. H. A. McCallum of London, Ontario, recently waited on the Ontario Cabinet at Toronto, presenting a request that an institute of hygiene be established in London in connection with the Western University. The government has replied that they can not at present accede to their application. The object of the university is to have the government build and maintain an institute equipped with laboratories for the purpose of providing scientific facilities for the prevention and treatment of infectious and epidemic diseases. The petitioners assert that something is due the western section of the province in view of the assistance granted Toronto and Queen's universities; they will prosecute their application at a future date.

Montreal General Hospital Report.—During 1902, 2,878 indoor patients were treated in the wards of the Montreal General Hospital, 55 more than for the previous year. In the outdoor departments there were 31,993 consultations. Of the total number of indoor patients, 166 remained over from the previous year; 2,894 were admitted during the twelve months, and 184 remained in the hospital at the end of the year. There were discharged from the hospital 2,652, and there died in the hospital 226. Of this number 88 died within three days of their admission. The death rate was 7.85, or 4.8 if the 88 were deducted. The total income amounted to $87,439, and the expenditure was $99,967, an excess of expenditure over income of $12,528. The average cost of patients per day was $1.49. At the annual meeting Dr. F. G. Finley was re-elected secretary for 1903.

Montreal Death Rate in 1902.—A striking feature in the death rate in Montreal during 1902 was the decrease of 700 over 1901. This has been, in most part, put down to the fact of the unusual cool summer of last year affecting the infant mortality to a very great degree, but also in part to the general improvement in the health of the city. By months the deaths were as follows: January, 481; February, 426; March, 534; April, 583; May, 547; June, 466; July, 735; August, 587; September, 440; October, 412; November, 484; December, 576. The total number of deaths was 6,271, as compared with 6,915 for 1901. Ten died from smallpox; 76 from measles; 64 from scarlet fever; 57 from diphtheria; 19 from croup; 28 from whooping cough; 26 from influenza; 86 from typhoid fever; 347 from diarrhea; 105 from cholera infantum; 664 from consumption, and 544 from pneumonia. Of 100 cities of America from which statistics could be secured, Hamilton, Ont., had the lowest death rate and Three Rivers, Que., the highest.

FOREIGN.

Tuberculosis Exposition at Odessa.—Russia has been holding an extensive exposition on all matters relating to tuberculosis.

Million to Hospitals.—The lay press reports the Savings Bank of Milan, Italy, as having given $1,000,000 to the hospitals of Lombardy to enable them to introduce the latest discoveries of science.

Dismissal of Suit for Damages Against Medical Journal.—Professor Lewin of Berlin, the author of an article on Antimorphin, denouncing it as containing morphin, and the two editors of the *Deutsche Med. Wochenschrift*, in which it appeared, were sued for damages by the manufacturer. The

suit was dismissed by the court and the costs assigned to the plaintiff.

Efforts by the Profession to Obtain Public Health Legislation.—According to the *Klin.-Therap. Woch.*, the medical chambers of Austrian Tyrol threaten that their members will go on a strike (*in den strike zu treten drohen*) if the members of the legislature do not abandon their obstruction of the measure in regard to matters affecting the public health. The measure was first brought up in 1900.

Parasite to Exterminate Mosquito.—It is announced by cable from Berlin that Dr. Dempwolff, who succeeded Professor Koch as the head of the German anti-malaria expedition to New Guinea, announces that he has discovered an aquatic insect which destroys the anopheles mosquito, and that he proposes to cultivate the creature artificially in the hope of exterminating the mosquito, thereby exterminating malaria.

Does Gypsum Dust Cure Tuberculosis?—The medical faculty of Berlin have been informed that there is no case of tuberculosis among the members of the Berlin Plaster-of-Paris Workers' Union, in spite of the fact that many were tuberculous when they entered the trade. Similar observations from other sources concerning workers in this material make a foundation for an investigation, and there is, therefore, issued an appeal for evidence and investigation.

Bier Called to Bonn.—Dr. A. Bier, professor of surgery at Greifswald, has accepted a call to Bonn as successor to the late Professor Schede. Bier is only 41, and yet his name has long been quoted as the discoverer of spinal cocainization, and the therapeutic application of passive congestion, or *Stauungshyperemie*. It is a curious fact that he is not at all enthusiastic in regard to spinal cocainization, but expressly warns against its dangers. It owes its vogue entirely to others.

Polar Expedition by a French Physician.—Dr. Jean Charcot is organizing a polar expedition for scientific research, aided by the Académie des Sciences of Paris and the ministry of public instruction, with private subscriptions. He will be accompanied by de Gerlache, the leader of the recent Belgian Antartic expedition; J. Bonnier, director of a marine laboratory, and several other experts. The Prince of Monaco is interested in the expedition, for which a special ship is being built.

Midwifery and Religious Scruples.—A midwife at Berlin recently refused to assist in an operation required to save the life of the mother but entailing the death of the fetus. Her religion forbade it, she said, and a second midwife had to be procured. Proceedings instituted against her for refusal to obey the physicians' orders resulted in the imposition of a fine and the warning that she must not attempt to serve as a midwife if her religion interfered with her professional duties in such cases.

Secret Medicines in Japan.—Very stringent laws have been enacted in Japan in regard to secret proprietary medicines. The importation of those containing a poison from which accidents might result is absolutely prohibited, as is, also, the sale of those that have deteriorated. The retailer must be informed in regard to the ingredients, proportions and doses, and must specify them in applying to the authorities for permission to sell the medicines. (See the discussion of the papers of Drs. Spratling and Jelliffe in this issue.)

Damages Awarded for Transmission of Syphilis.—The French courts, for the first time, have taken up the matter of venereal transmission of syphilis, and in a suit recently decided at Paris awarded $2,400 to the victim, a girl of 16. It was established that the young man in question knew that he had syphilis and also was aware of its contagious character, when he commenced the liaison with the girl. It continued for four months before she displayed evidences of infection. The decree states that "the communication of a contagious disease is a misdemeanor (*faute*), even when it does not occur intentionally, and results merely from the imprudence or negligence of the subject."

Blue Electric Light as an Anesthetic.—THE JOURNAL has previously referred to Minin's discovery of the therapeutic and anesthetic value of blue electric light. He has recently found that the anesthesia is sufficient for even important operations, and performed two herniotomies with it practically alone. One was a Bassini on a colonel. Cocain was injected previous to, and the blue light applied during, the operation. In the second case the cocain was omitted, and the ligation of the sac elicited some pain, but not severe. The operation lasted twenty minutes in each, and both healed by first intention. All the minor operations at a certain hospital at St. Petersburg are done under blue light as the exclusive anesthetic. Minin has just been appointed chief of the Nicolaj Military Hospital.

New Campaign Measure Against Fake Ads.—A pharmacist at Herborn, near Wiesbaden, named Stoll, has made an arrangement with the proprietors of the local daily to have space reserved for him after every fake ad. In this space he describes the substances lauded in the flaming ad. above, and states where they can be obtained and the ordinary price. For instance, a display ad. portraying the virtues of "*homeriana*," at so much a bottle, is followed by his statement that homeriana, or bird's knot grass, is a common weed found along the country roads and can be had at all drug stores for a few pennies. The ad. of the "Volta Cross" was followed by his announcement: "Volta Cross, worth 10 cents (according to proclamation of the Berlin chief of police), sold for 75 cents. The manufacturer has been compelled to leave Berlin and has removed to Munich." Stoll's announcement in the Volta Cross matter forced the town authorities to interfere and regulate its advertisement. One of his ads.: "Common weed, found at the Shooting Park and along the roads, etc.," he inserted twenty-seven times. The manufacturers have now abandoned advertising at Herborn.

Report of Committee on Hypnotism.—The Prussian authorities recently requested of the central medical chamber an opinion of hypnotism. The report was recently mentioned in brief in THE JOURNAL. Professor Mendel, as chairman of the committee, states in the report: "Careful distinction must be made between the cure of an affection and the alleviation of its symptoms by hypnotism. No physician claims that it is possible to cure with it an organic affection susceptible of demonstration with our modern diagnostic measures. But hypnotic or waking suggestion is undoubtedly capable of banishing, usually temporarily but sometimes even permamently, the most widely diverse symptoms of the affection—but without curing it. Success is dependent in this case, as in all cases of suggestion, on the greater or less skill of the suggestor, his personality, on external circumstances and on the degree of receptivity of suggestion by the patient. A number of cases are known in which mental disturbances developed in predisposed individuals under hypnotization. Some of these cases occurred with charlatans, but in others the hypnosis had been conducted by physicians."

Correspondence.

Adenoids as a Route of Tubercular Invasion.

LOS ANGELES, CAL., Feb. 16, 1903.

To the Editor:—In Dr. Freudenthal's article on "Adenoids" in THE JOURNAL, Feb. 7, he says: "If, for some reason or other, the path of the tubercle bacillus downward is closed up, by adenoids or other causes, it makes its way to the cranial cavity, where a tuberculous meningitis, so frequent among children, is set up." Such a statement, coming from a man of Freudenthal's prominence, is likely to lead many into wrong conceptions regarding the method of infection in tuberculosis.

Dr. Freudenthal is challenged to explain the anatomic route and steps of infection from the adenoid to the meninges or to any portion of the body, or to the lungs. A great many writers are advancing the theory that nearly all our tuberculous infections, even of the lungs, are through the tonsils or adenoid tissue. In this country Lartigau is the most prominent claimant for this mode of infection. Notwithstanding the prominence of all these writers, they are challenged to show us definitely and unmistakably, or at least anatomically, how these infections take place. We must ask them, how does the bacillus reach the meninges from an adenoid or from a tonsil? Or, to make the problem easier, how does the bacillus reach the lungs from the adenoid tissue or from the tonsils? If these writers admit that the bacilli enter the blood vessels of the diseased adenoid, we could understand then that it was possible for an infection to take place and in such a manner. Or if they contend that it is the lymphatics that pick up bacilli and convey them to their final destination, we are confronted with the fact that these bacilli are, after all, poured into the great veins in the deep angles of the neck unless arrested in the cervical ganglia.

In any or either event, by whatever anatomic route they may follow, the bacilli are emptied into the right side of the heart, traverse the pulmonary circulation, to be sent—we know not where. One can not feel that adenoids and tonsils play much of a rôle in tuberculous infections of any kind except of cervical ganglia.

Writers have accounted for cerebromeningitis and tuberculous meningitis by entrance of the respective organisms into the cranium through the cribriform plate of the ethmoid. It is true that the dura sends processes along the olfactory nerves and that the lymph radicals of these processes empty into the dural vessels. But really is not this reaching out and dragging anatomy in by the hair of the head when we have the greater possibility of these organisms gaining entrance through the great surface-area of the respiratory mucous membrane?

If we examine into the anatomic distribution of the lymphatics of the nasal, pharyngeal, laryngeal and bronchial mucous membrances, we shall note that a bacterium or other foreign body, to reach the circulation through these, would have to run the gauntlet of a numerous outpost of glands established by Nature in this locality for the very purpose of arresting foreign matter. We know that foreign matter, such as coal dust, does reach these glands for the pigment in them is demonstrable, and still there is, comparatively speaking, very little coal dust that reaches the circulation or the glands themselves, through the lymphatics of the upper respiratory tract. It is but reasonable to believe that micro-organisms arrested in lymphatic glands have less chance of reaching the circulation than if they grew in one of our great organs. Lymphatic glands are especially adapted for the destruction of bacteria and probably do so to a very large extent in all diseases except syphilis and the carcinomata. If bacteria, tubercle bacilli especially, enter our bodies through the tonsils and adenoids, as so many writers would have us believe, I would point out and controvert their position by calling attention to the infrequency of infection of the deep cervical glands through which these organisms would have to travel; and to the further observation made elsewhere, that if bacilli do enter the circulation in this manner, it is, nevertheless, the bronchial glands that show the constant arrest of the organisms. Notwithstanding Lartigau's recent report of finding tubercle bacilli in a large percentage of tonsils and adenoid tissue, it is only fair to presume that there certainly could be little difference in the functions of the cervical and bronchial glands and there is no more valid reason to suspect that bacilli will pass the cervical ganglia without harm than that they will pass the bronchial glands without arrest. It is very likely, then, that the resistance of the deep cervical glands is very effective in barring the entrance of bacteria to the circulation.

Usually the first arrest of bacilli is in the bronchial glands. "Pizzini inoculated lymph glands from forty people who had died of accident or acute disease into guinea-pigs. From the results of the inoculation experiments, he concluded that 42 per cent. of healthy people have tubercle bacilli in their glands, mostly in the bronchial. Statistics of the Paris morgue show that a considerable proportion of all who die of accident or suicide have evidences of some tuberculous disease in connection with the respiratory system" (Lartigau). This observation would lead one to believe that the bronchial glands are combating the constant invasion of small numbers of bacilli more or less successfully; and to have reached the bronchial glands, it is the most reasonable thing to suppose that bacilli have been inspired to the air vesicle itself, penetrated its wall and reached some of the underlying vessels, most often the lymphatic.

Why one should fix his attention on the tonsil or adenoid tissue to explain the infection of tuberculosis is utterly puzzling, when the experiences of the necropsy room show us the lungs of miners, firemen, or those living in dusty environments, pigmented throughout with fine coal deposits. These deposits usually follow the paths of distribution of the lymphatics, and often can be easily traced with the naked eye. In such cases we may find the bronchial glands gritty from this coal dust which had been arrested by these efficient protectors of our bodies.

If coal dust and other dust reaches the lymphatics of the lungs through the air vesicles, as it certainly does, why need we consider the adenoid, or the tonsil, as the principal path of invasion? If coal dust, then why not tubercle bacilli?

Respectfully yours,

J. O. COBB,
Surgeon, United States Marine-Hospital Service.

The First Hepaticotomy—Credit to America.

FREMONT, OHIO, Jan. 30, 1903.

To the Editor:—Some reviews of the history of surgery on the bile ducts, the German literature especially, give Kocher credit for having made the first hepaticotomy. Professor Courvoisier of Basel, Switzerland, in his work on "Pathology and Surgery of the Bile Ducts," published in 1890, also mentions the fact that Kocher made his first hepaticotomy, 8, xi, 1889. Since history principally consists in recording and comparing facts in their relation to human actions I think I may be justified in referring you to a case which I published in THE JOURNAL of the American Medical Association, March 31, 1888, under the title "Operation for Gallstones; Congenital Absence of Gallbladder." It is probably due to the fact that I did not coin a new Greek name for this operation that it has been overlooked, as in all other details it could be called a hepaticotomy. I wrote to Professor Courvoisier about 10 years ago and sent him a copy of the article, in response he said that he did not have access to that number of THE JOURNAL before, but that in his future publications he would give due recognition to the above fact. This has not been done so far, not in Kocher's and Quervain's "Encyklopædie der gersammten Chirurgie," where Courvoisier writes on hepaticotomy, nor in the latest number of the *Archiv f. Klinishe Chirurgie*, vol. 69, where Erich Berger reports on hepaticus drainage in Professor Hans Kehr's klinick.

M. STAMM.

State Boards of Registration.

New Arkansas Law.—The new medical practice act passed by the Arkansas legislature and signed by the governor goes into effect 90 days from date of its passage, or early in April of this year. It provides for three boards, homeopathic, eclectic and regular, appointed by the governor from lists furnished by the respective state medical societies. These are to hold four regular stated examinations each year, on the second Tuesdays in January, April, July and October, at such place as the majority may agree on, after consulting the convenience of the boards and the applicants for examination. Any one hereafter desiring to practice medicine in Arkansas must go before a board, making his application to the secretary, with a $10 fee, and submit to examination, which may be written or oral, at the discretion of the board. It must be of a practical character, including anatomy, physiology, chemistry, materia medica, theory and practice of medicine, surgery and obstetrics. If the applicant possesses the necessary qualifications, in the opinion of the board, a certificate will be granted. Certificates must be recorded in the office of the county clerk where the holder is practicing. Temporary permits are allowed on the payment of a $10 fee, but can not continue in force beyond the next meeting of the board, and may in no case be granted within six months after refusal of certificate. No fee is to be charged an applicant who has previously paid the charge for a temporary permit. The penalty for irregular practice is a fine of not less than $25 nor more than $500, or by imprisonment in the county jail of not less than ten days or more than ninety days, or both. Each day of such practice shall constitute a separate offense. Any person is regarded as practicing medicine in any of its departments within the meaning of the act who shall append M.D. or M.B. to his name, or repeatedly prescribe or direct for use to any person or persons any drug, medicine or other agency for the treatment, cure or relief of any bodily injury, deformity or disease, provided that nothing in the act shall be so construed as to prevent the gratuitous administering of domestic remedies or shall apply to midwives. Nothing is specified as regards diplomas, which seem not to be required.

Kansas.—Dr. H. W. Roby, secretary of the Kansas State Board of Medical Registration and Examination, reports the examination held at Topeka, Feb. 10 and 11, 1903, as follows: Number of subjects examined in, 9; total number of questions, 90; percentage required to pass, 70; the examination is written, except in case of those physically unable to write, as paralytics or invalids; total number examined, 22; passed, 20; failed, 2.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

PRIORITY IN COLLES' FRACTURE REDUCTION METHOD.

CHICAGO, Feb. 23, 1903.

To the Editor:—On page 542 of your February 21 issue I notice an item from the *Northwestern Lancet*, Minneapolis, by A. M. Pond, on "Some Considerations of Colles' Fracture." The method of reduction which he describes is not original, as it has been delineated at some length by Joseph Griffiths in the *British Medical Journal* of Dec. 7, 1901. I am in perfect accord with the treatment and results obtained as I have used the same method for some time, my attention being first directed to it by the article above named.

ARTHUR ATWELL SMALL.

ANS.—Pond said he had never seen the method described.

ARTIFICIAL MUD BATHS WANTED.

CONFLUENCE, PA., Feb. 16, 1903.

To the Editor:—Please inform me where I can get fango for mineral mud treatment as mentioned in THE JOURNAL, p. 447, February 14; also where I can get additional literature on the treatment.

R. J. HEMMINGER.

ANS.—Fango is the name used in Italy for the mud-bath treatment. The material is said to be a sort of finely divided volcanic earth. We presume that it has no very special properties over those possessed by the medical mud baths in this country. We know of no way by which it could be obtained in this country. There is no special literature known to us on the "fango" treatment in our language, and not very much on mud baths, except what is given in general works on balneology, etc.

MEDICAL PRACTICE QUERIES.

BLOOMFIELD, IOWA, Feb. 23, 1903.

To the Editor:—Please inform me as to the requirements to practice medicine in Kansas, also the name of the secretary of the state board, with address. C. L. KEMBEL.

ANS.—A diploma and examination are, we believe, now required. Dr. H. W. Roby, Topeka, Kan.

BALTIMORE, Feb. 15, 1903.

To the Editor:—Will you kindly inform me if the Maryland State Board will register any one who has successfully passed the Pennsylvania Board, without requiring an examination in Maryland? If they do, how much registration fee.

Yours most respectfully, A. H. BRAECKLEIN.

923 Barre Street.

ANS.—The board of examiners are authorized to do so if they consider the requirements equal to their own. Write them.

Marriages.

D. L. ROSE, M.D., Sherman, Mich., to Miss Gale Hooper of Battle Creek, Mich., January 31.

CYRUS W. STRICKLER, M.D., to Miss Annie Virginia Williams, both of Atlanta, Ga., February 25.

G. H. RATHBUN, M.D., Roubaix, S.D., to Miss Mollie McArthur, at Lead, S.D., February 9.

WILLIAM W. MELOY, M.D., Chicago, to Miss Charlotte A. Logan of Brooklyn, N. Y., February 25.

Deaths.

William Elias Brownlee Davis, M.D.

A telegram received by THE JOURNAL just before going to press announces that Dr. W. E. B. Davis was killed Tuesday night, February 24, by being thrown under a moving train by a frightened horse. Thus suddenly has ended a life of more than ordinary usefulness, and the shock will be felt not only in the south, where he was so well known and loved, but all over the country. The loss to the profession is great; he was, first and always, a polished gentleman; in his chosen field of gynecology and surgery he was a leader of men, and in his intercourse with his professional fellows he was the personification of ethical courtesy.

He was born in Trussville, Ala., Nov. 25, 1863, and was, therefore, 39 years of age. He was the third in a line of

physicians. After being graduated from the University of Alabama, he took up the study of medicine in 1881 under the preceptorship of his brother, Dr. J. D. S. Davis of Birmingham. After attending three courses of lectures, the last of which was taken at Bellevue Hospital Medical College, he was graduated from that institution in 1884. He then practiced in Birmingham with his brother for three years, after which he studied in the hospitals of London, Berlin and Vienna for two years. On his return to America he practiced for a short time in Rome, Ga., and then returned to Birmingham, where he since resided and practiced with his brother, Dr. J. D. S. Davis, devoting his attention chiefly to operative gynecology.

He was an honored member of many medical societies—the American Medical Association, vice-president in 1891, secretary of the Section on Surgery in 1890, and chairman of the Section on Obstetrics and Diseases of Women in 1899; Medical Association of the State of Alabama; Jefferson County Medical Society; Birmingham Medical Society; Southern Surgical and Gynecological Association, secretary, 1888 to 1900, and president, 1901-1902; American Association of Obstetricians and Gynecologists, vice-president in 1895, member of executive council, 1897-1900, and president, 1901; honorary president of the Section on Gynecology and Abdominal Surgery of the first

WILLIAM ELIAS BROWNLEE DAVIS, M.D.

Pan-American Medical Congress, Washington, D. C., 1893; honorary member of the British Gynecological Society; one of the founders of the Alabama Surgical and Gynecological Association, and its secretary in 1887-1888; Tri-State Medical Society of Alabama, Georgia and Tennessee, and its president in 1892; honorary member of the Medical Society of the State of New York.

He was surgeon to the Birmingham Hospital of United Charities in 1891-1892, and through his efforts a department of diseases of women was established. In 1894 he was elected professor of gynecology, obstetrics and abdominal surgery in the Birmingham Medical College.

Dr. Davis and his brother were editors of the first medical journal to be published in Alabama, the *Alabama Medical and Surgical Journal*, in 1886 and 1887; from 1890 to 1893 he was editor of the gynecological department of the *Alabama Medical and Surgical Age*, and he was associate editor of the *American Gynecological Journal*. His contributions to medical literature were numerous and valuable. Most of his later work was in the line of abdominal surgery, surgery of the bile-ducts.

He was buried from the South Side Baptist Church, Birmingham, February 27, at 11 a. m.

John Frank Valentine, M.D. College of Physicians and Surgeons, New York, 1879, for 12 years surgeon of the Thirty-second Regiment, N. G., S. N. Y., coroner's physician, chief surgeon of the Long Island Railroad, member of the Queens-Nassau Medical Society, and past president of the New York State Association of Railway Surgeons, died from typhoid fever at his home in Richmond Hill, Long Island, February 5, after an illness of several weeks, aged 46. The medical staff of St. John's Hospital, of which Dr. Valentine was president, at a special meeting, February 6, passed resolutions of respect and regret.

Caleb W. Hornor, M.D. Jefferson Medical College, Philadelphia, 1849, who did a large and distinguished work during the Civil War, being in charge of various important hospitals and chief medical officer of the Freedmen's Bureau, in the course of which he organized and administered over 80 hospitals and dispensaries throughout the south, died at his home near Bryn Mawr, Pa., February 8, from pneumonia, after an illness of two weeks, aged 74. He was a member of the American Medical Association.

Earle Eugene Woolworth, M.D. New York University, 1897, died February 5 at the Brooklyn Hospital from injuries received in a runaway accident, January 21, aged 30. He resided in Brooklyn and was a member of the New York State Medical Association, the Kings County Medical Society and the Alumni Association of the City Hospital.

Vincent P. Kennedy, M.D. Rush Medical College, 1856, a pioneer resident of Meeker County, Minn., surgeon of the Fifth Minnesota Volunteer Infantry in the Civil War, a member of the state legislature for two terms, died from uremia at his home in Litchfield, Minn., February 13, aged 79. He retired from active practice in 1888.

Harry Herbert Hurst, M.D. University of Pennsylvania, Philadelphia, 1897, member of the Pittsburg Pathological Society and former president of the Wilkinsburg Medical Club, died at his home in Wilkinsburg, Pa., from typhoid fever, January 31, after an illness of five weeks, aged 28.

Benjamin T. Shimwell, M.D. Jefferson Medical College, Philadelphia, 1875, formerly professor of surgery at the Medico-Chirurgical College, and a member of the American Medical Association, died at the Medico-Chirurgical Hospital, Philadelphia, from consumption, February 5, aged 51.

Gustavus Bruhl, M.D. University of Munich, Bavaria, 1848, a member of the American Medical Association, and an ardent student of ethnology and history, died from apoplexy at his home in Cincinnati, February 16, aged 76.

Henry Hulme Warburton, M.D. London Hospital School of Medicine, the pioneer physician of the Pacific Coast, where he had practiced since 1847, died at his home in Santa Clara, Cal., from pneumonia, February 9, after an illness of four days, aged 83.

James H. O'Toole, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1880, a member of the Massachusetts Medical Society, died from angina pectoris at his home in Charlestown, Mass., January 27, after a short illness.

Frank O'Neil, M.D. University of Southern California, Los Angeles, Cal., a member of the medical staff of the Southern Pacific Railway, died at a construction camp 80 miles west of Nevada City, January 19, from pneumonia.

David Munro, M.D. Faculty of Medicine of Queen's University and Royal College of Physicians and Surgeons, Kingston, Ontario, 1867, died suddenly from heart disease at his home in Perth, Ont., February 7, aged 61.

Nelson B. Sisson, M.D. University of Louisville, Ky., 1846, died at his home in Porter, Ohio, January 28, aged 82. During the Civil War he served as assistant surgeon of the Ninety-second Ohio Volunteer Infantry.

Edward von Donhoff, M.D. Heidelberg, Germany, formerly professor of surgery in Louisville Medical College, died in Bellevue Hospital, New York, from the excessive use of drugs and dissipation, February 7.

Charles C. Warden, M.D. Ohio Medical College, Cincinnati, 1843, the first physician to locate in Ottumwa, Iowa, who retired from practice in 1856, died at his home in Ottumwa, February 14, aged 86.

Flavien Dupont, M.D. Laval University, Quebec, 1880, formerly of Montreal, but for the last three years a resident of Boston, died at Notre Dame Hospital, Montreal, from Bright's disease, aged 40.

John Morris, M.D. Starling Medical College, Columbus, Ohio, died at his home in Chicago, from heart disease, after a long illness, aged 67. He had not practiced since the close of the Civil War.

Henry Tomboeken, M.D. Rush Medical College, Chicago, 1866, who retired from practice in Chicago in 1898, died at

Terre Haute, Ind., from cancer of the stomach, February 7, aged 65.

Walter Pardee, M.D. Cleveland (Ohio) University of Medicine and Surgery, 1860, died at the home of his son in New York City, February 11, after an invalidism of twenty years, aged 80.

Gertrude H. Woodworth, M.D. Hahnemann Medical College, Chicago, 1897, died at her home in Chicago, February 10, from the effects of chloroform taken with suicidal intent, aged 55.

Doctor N. Porter, M.D. Kentucky School of Medicine, Louisville, 1851, who retired from active practice ten years ago, died suddenly at his home in Eminence, Ky., January 29, aged 87.

John C. Whaley, M.D., state senator, and for many years a practitioner of Osceola, Mo., died at his home in that city, February 3, from pneumonia, after a short illness, aged 64.

Alonzo D. Root, M.D. Cleveland Medical College, 1871, died at his home in Crete, Neb., from chronic Bright's disease, after an illness of several years, February 8, aged 66.

George A. Harris, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1873, died suddenly from heart disease at his home in Bridgeton, N. J., February 9, aged 58.

John E. Wood, M.D. Starling Medical College, Columbus, Ohio, 1894, died at his home in Marysville, January 27, from consumption, after an illness of four years, aged 29.

George H. Douglas, M.D. Tulane University, New Orleans, 1886, quarantine surgeon at, and formerly mayor of, Morgan City, La., died recently at Pensacola, Fla., aged 42.

Henry M. Ptolemy, M.D. Detroit College of Medicine, 1889, died at his home in Brighton, Mich., February 16, from Bright's disease, after a lingering illness, aged 47.

Charles B. Leavitt, M.D. University of Pennsylvania, Philadelphia, 1882, died at his home in Trenton, N. J., from pneumonia, February 8, after an illness of two weeks.

Henry Newland, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1876, died at his home in Los Angeles, Cal., January 7, after an illness of two years, aged 75.

Ralph L. Seckler, M.D. University Medical College of Kansas City, Mo., 1900, of Basehor, Leavenworth County, Kan., died recently in San Francisco, from paralysis.

Charles Wetherill Gambes, M.D. Jefferson Medical College, Philadelphia, 1864, died suddenly from heart disease at his home in Oaks, Pa., January 31, aged 62.

Frank C. Hoegel, M.D. Western Pennsylvania Medical College, Pittsburg, Pa., 1897, died from typhoid fever at his home in Allegheny, Pa., February 2, aged 27.

John M. McFarland, M.D. Tulane University, New Orleans, 1870, died at his home in Rivera, Cal., February 13, aged 55.

David F. Van Aken, M.D. Albany Medical College, 1860, died at his home in Malden, N. Y., January 30, aged 69.

Association News.

THE NEW ORLEANS NUMBER.

Announcement of the Special Number of THE JOURNAL *for April 11.*

The issue of THE JOURNAL of April 11 will be the special New Orleans Number and will be an announcement of the coming fifty-fourth annual meeting of the American Medical Association, to be held at New Orleans May 5 to 8, 1903. It will contain an illustrated article on Louisiana and New Orleans, their history and points of interest, and will give all the facts possible about the arrangements for the meeting, including a list of hotels, with rates, railroad rates, fare from important centers, announcement of special trains, side trips, excursions, opportunities for sight seeing, entertainments, schedules of meetings, places of meeting, etc. It will also contain the preliminary program of each of the sections.

In this number all special trains should be announced. We therefore ask every committee or official to send us at an early date detailed information of such trains as may be arranged. The Mississippi River excursion to New Orleans, mentioned on page 532 last week, and the ocean trip from Boston and New York, suggested in this issue, are attractive features that should be fully announced in the April 11 issue. We desire to receive information also of any other features not mentioned above, which will be of interest to some or all of the several thousands who are expected at New Orleans.

RATES TO NEW ORLEANS.

One Fare in Southwestern Association Territory—One and One-Third in Transcontinental.

The following letters explain themselves. The Southwestern Passenger Bureau includes railroads operating in Texas, Oklahoma and Indian Territories and the southern half of Missouri.

Southwestern Passenger Bureau.

ST. LOUIS, Jan. 27, 1903.

S. P. B. CIRCULAR LETTER, No. 5827. PROPOSITION ACCOUNT ANNUAL MEETING, AMERICAN MEDICAL ASSOCIATION, NEW ORLEANS, MAY 5-8, 1903, ADOPTED.

To Interested Lines:—Referring to S. P. B. Consultation Letter No. 843 submitting the following to apply from points in Texas, account annual meeting, American Medical Association, New Orleans, La., May 5-8, 1903:

RATE.—One regular, first-class fare for the round trip.

DATES OF SALE.—May 3 and 4, 1903.

LIMITS.—Tickets to bear continuous passage transit limit in each direction, with final limit of May 16, 1903.

EXTENSION.—If tickets are presented in person by original purchasers and fee of 50 cents paid to Special Agent on or before May 12, 1903, extension of final limit may be secured to and including May 30, 1903.

Special Agency will be conducted in the name of Mr. Joseph Richardson at Room 204, No. 204 Camp Street, New Orleans, and will be open between the hours of 8 a. m. and 8 p. m., tickets to be withdrawn only on the date on which they are to be used, and to be available for passage leaving New Orleans only on such date. The extension of limit to in no case exceed midnight of May 30, 1903.

The Special Agent will use paster bearing fac-simile signature of Joseph Richardson.

No objection having been recorded, the proposition is hereby declared adopted.

Respectfully, (Signed) C. M. PRATT, Chairman.

Transcontinental Passenger Association.

CHICAGO, Feb. 5, 1903.

MEETING OF AMERICAN MEDICAL ASSOCIATION, NEW ORLEANS, MAY 5-8, 1903.

Edmond Souchon, M.D., Chairman Committee on Transportation, New Orleans.

Dear Sir:—In reply to your favor of 2d instant I beg to say that the attendance from the states from which our lines sell, namely, California, Nevada, Washington and Oregon, will doubtless be so small as not to justify the making of any special reduced rate from those states.

Delegates may, however, avail themselves of the regular nine months' rate, which is in effect daily from Pacific Coast points to New Orleans, and which approximates two cents per mile in each direction, or about one fare and a third for the round trip.

Should it happen that your delegates apply at a station on Pacific Coast from which the nine months' rate is not in effect, which may be the case at very small, unimportant stations, the agent will cheerfully ascertain and advise them the nearest point to his station from which such rate does apply.

It is hoped that the foregoing will be satisfactory to you.

Respectfully, (Signed) J. CHARLTON, Chairman.

To New Orleans from Boston by Sea.

PLYMOUTH, MASS., Feb. 18, 1903.

To the Editor:—Will you kindly tell me: 1. What is the rate of fare from Boston to New Orleans to the annual meeting? 2. How do I get the reduced rate? 3. Is there any reduced rate by boat from Boston or New York to New Orleans? 4. Are there any reduced hotel rates? 5. Can I take my wife at same rate as myself? Yours truly, H. H. BURNS.

Answer.—Concerning all your questions read what is said on this page under the head of "New Orleans Number." 1. We are informed that the regular one-way rate is about $39, divided as follows: Boston to New York about $5, New York to

Washington $6.50, Washington to New Orleans, $27.50. The rate from Washington to the New Orleans meeting will be one fare for the round trip. East of Washington we are not informed as to the rates granted. As soon as we are, they will be announced in THE JOURNAL. If the same rate is given in the east as the southeast, it would make the round trip from Boston to New Orleans about $39. 2. Ask your ticket agent or the agent of the Boston and Albany R.R. in Boston. Consult THE JOURNAL, January 3, p. 46, and January 31, p. 325. 3. None to our knowledge. There should be. Some of the New York and Boston physicians may work this up. 4. None have been announced. 5. Yes.

Medical Organization.

Official Representative On Organization.

At the annual meeting of the Board of Trustees of the American Medical Association, held in Chicago, February 20-21, Dr. J. N. McCormack was asked by the board to devote his whole time to the work of organization as the representative in this work of the American Medical Association. Dr. McCormack has accepted the position and will immediately enter on his duties. It is expected that he will spend much of his time in the field and will be at the command of such state societies as may think his services can be made useful to them. It is suggested that officers of the various state societies and such committees as have this work of organization in charge, especially the councilors of the reorganized state societies, will put themselves in communication with him, with a view of co-operation in the work. Such co-operation will consist in both correspondence and personal visits on the part of Dr. McCormack, as may be desired. All correspondence in the future in regard to organization should be directed to Dr. J. N. McCormack, Bowling Green, Ky.

Effect of Organization.

A correspondent from Little Rock, Ark., sends us a copy of the new medical practice act just passed and signed by the governor, and says, "Although only in the incipiency of organization, we were able only by this means to get the bill through our legislature. Heretofore lack of organization made it easy for any organized effort to oppose and defeat us."

Defiance County (Ohio) Medical Society.

At a very full regular meeting in Defiance, February 11, this society adopted the constitution proposed by the committee of the American Medical Association.

Franklin County (Tenn.) Medical Society.

This society was organized at Winchester, February 19, with Dr. Flavel B. Sloan, Cowen, president; Dr. Thomas B. Anderton, Winchester, vice-president, and Dr. Garner S. Warren, Decherd, secretary.

Hamilton County (Iowa) Medical Society.

This society was organized February 7. Dr. Frank E. Whitley was elected president; Dr. Alanson M. Pond, vice-president; Dr. Carl W. Rummel, secretary, and Dr. Belle Conrad, treasurer, all of Webster City.

Lenawee County (Mich.) Medical Society.

On January 13, at Adrian, this society was reorganized with the assistance of Dr. Albert E. Bulson, councilor for the district. The constitution and by-laws suggested by the American Medical Association for county societies were adopted, and Dr. Clifford Kirkpatrick re-elected president and Dr. David L. Treat, secretary and treasurer, both of Adrian.

Licking County (Ohio) Medical Society.

The Licking County physicians met at Newark, February 12, and organized this society, electing Dr. Anderson T. Speer, Newark, president; Dr. Charles A. Foster, Newark, vice-president; Dr. George W. Garrison, Utica, treasurer; Dr. H. Burner Anderson, Newark, secretary, and Drs. B. H. Barnes, William H. Knauss and Cary F. Legge, all of Newark, censors. A committee on constitution and by-laws was also appointed.

Madison County (Ky.) Medical Society.

The physicians of Madison County met at Richmond, February 5, to consider the question of organization. After an address by Dr. Isaac A. Shirley, Winchester, councilor of the Tenth District, a permanent organization was effected, with Dr. James M. Poyntz, Richmond, president, and Dr. Murison Dunn, Richmond, secretary. The constitution and by-laws prepared by the American Medical Association were adopted.

Menominee County (Mich.) Medical Society.

Dr. Theodore A. Felch, Ishpeming, councilor for the Twelfth District, met with the physicians of the county at Menominee, January 14, explained the plan of reorganization suggested by the American Medical Association, and perfected the organization of the county society. Dr. Benjamin T. Phillips, Menominee, was elected president; Edward Sawbridge, Stephenson, vice-president; Dr. Peter J. Noer, Menominee, secretary and treasurer, and Drs. Walter R. Hicks, Eugene J. Grignon, and John F. Hicks, all of Menominee, directors.

Societies.

Pasadena (Cal.) Medical Society.—At the annual meeting, January 13, Dr. Charles D. Lockwood was elected president; Dr. Fitch E. Mattison, vice-president, and Dr. John E. Janes, secretary and treasurer.

Polk County (Neb.) Medical Society.—The physicians of Polk County recently met at Osceola and organized a county society, with Dr. Carrie L. Heald as president and Dr. L. Matt Shaw, secretary-treasurer, both of Osceola.

Merrick County (Neb.) Medical Society.—The physicians of the county met in Central City, January 13, and organized a county society auxiliary to the Nebraska State Medical Society. Dr. E. A. Benton, Central City, was elected president.

Marquette County (Mich.) Medical Society.—This society, at its annual meeting in Marquette, January 13, elected Dr. John H. Andrus, Ishpeming, president; Dr. Harry J. Hornbogen, Marquette, treasurer, and Dr. George D. Beach, Champion, secretary.

Van Buren County (Mich.) Medical Society.—The first annual meeting was held at Hartford, January 13. Dr. George D. Carnes, South Haven, was elected president; Dr. James Murphy, Bangor, vice-president, and Dr. Norris A. Williams, Bangor, secretary and treasurer.

Kaufman County (Texas) Medical Society.—At the annual meeting held in Kaufman, January 13, Dr. William H. Monday, Terrell, was elected president; Dr. Burrel J. Hubbard, Kaufman, vice-president; Dr. Willis J. Pollard, Kaufman, secretary, and Dr. Delana P. Hicks, Kaufman, treasurer.

Jackson County (Iowa) Medical Society.—At the annual meeting, held in Maquoketa, January 29, Dr. William C. Post, Welton, was elected president; Dr. George M. Johnson, Maquoketa, vice-president; Dr. J. O. Ristine, Iron Hills, secretary, and Dr. Willis A. Scott, Maquoketa, treasurer.

Rolla District (Mo.) Medical Society.—At the semi-annual meeting held in Rolla, Dec. 11, 1902, Dr. James P. Dunigan, Sullivan, was elected president; Dr. Stuart L. Baysinger, Rolla, vice-president; Dr. Samuel B. Rowe, Rolla, secretary, and Dr. Samuel H. Headlee, St. James, treasurer.

Hawaiian Territorial Medical Society.—At a recent meeting held in Honolulu the following officers were elected: Dr. H. C. Sloggett, president; Dr. W. L. Moore, vice-president, and Dr. Jonathan T. McDonald, secretary and treasurer, all of Honolulu. The annual meeting will be held at Honolulu, November 7.

Center County (Pa.) Medical Society.—At the annual meeting, February 10, the following officers were elected: President, Dr. Charles E. McGirk, Phillipsburg; vice-presidents, Drs. Edwin S. Dorworth, Bellefonte, and W. U. Irwin, Fleming; secretary, Dr. J. Y. Dale, Lemont; treasurer, Dr. Geo. F. Harris, Bellefonte.

Riverside County (Cal.) Medical Society.—At the quarterly meeting held in Riverside, January 13, Dr. Oscar J. Kendall was elected president; Dr. Charles W. Girdlestone, vice-president, and Dr. William W. Roblee, secretary and treasurer, all of Riverside. The society voted to affiliate with the Medical Society of the State of California.

Oklahoma Territorial Medical Association.—At the annual meeting held in Enid, January 15, the following officers

were elected: Dr. John A. Hatchett, El Reno, president; Drs. Orlando D. Taft, Garber, and Roger L. Hall, Medford, vice-presidents, and Dr. Mahlon A. Kelso, Enid, was, for the third time, re-elected secretary and treasurer.

Warren County (Ky.) Medical Society.—At the annual election held in Bowling Green, January 10, Dr. Thomas W. Stone, Bowling Green, was elected president; Dr. Eldon N. Hall, Woodburn, vice-president; Dr. Fred D. Cartwright, Bowling Green, secretary and treasurer, and Dr. J. N. McCormack, Bowling Green, delegate to the Kentucky State Medical Society.

Washington County (R. I.) Medical Society.—At the annual meeting in Westerly, January 8, the following officers were elected: Dr. C. Grant Savage, Westerly, president; Drs. Milton A. Duckworth, Carolina, and Edward J. Knerr, Hope Valley, vice-presidents; Dr. J. Howard Morgan, Westerly, secretary and treasurer, and Dr. Elisha P. Clarke, Hope Valley, Auditor.

Tri-County (Cal.) Medical Society.—This society, which includes the physicians of San Benito, Monterey and Santa Cruz counties, met in Watsonville, January 6, and elected the following officers: President, Dr. Frank H. Patterson, San Juan; vice-presidents, Drs. Spencer C. Rodgers, Watsonville, Henry C. Whiting, Santa Cruz, R. W. O'Bannon, Hollister, and Dorus Brumwell, King City, and Dr. Saxton T. Pope, Watsonville, secretary.

Green County (Ohio) Medical Society.—This society met, February 5, at Xenia. Drs. Horace Bonner, Dayton, Brooks F. Beebe, Cincinnati, and Dr. C. L. Bonifield, Cincinnati, presented convincing arguments why this society should affiliate with the state society and adopt the by-laws as suggested by their committee. The discussion of the question of new by-laws occupied so much time that their further discussion and adoption was laid over until the next meeting, March 5.

CINCINNATI ACADEMY OF MEDICINE.

Regular Meeting, held Feb. 16, 1903.

The President, Dr. A. B. Isham, in the Chair.

The evening was devoted to the consideration of "Medical Organization."

The Subject Stated.

Dr. Brooks F. Beebe, chairman of council, Ohio State Medical Association, said in substance: Not a physician's name in the hall of fame; no just recognition of his worth by the public at large; intelligent, law-abiding, unselfish, as he is, conscientious in his work; progressive in his methods and his science; altruistic to a degree not equaled by others; still, medical men, with rare exceptions, do not occupy that place in the world of affairs that they should. Neither do they exert that influence of which they are capable, nor meet with the pecuniary reward that should be theirs. Where lies the fault? Chiefly in themselves. Only 30,000 out of a possible 120,000 physicians in the United States belong to medical societies. Three times as many out as in. Are we three times as bad as we should be? Why is it that physicians are so apathetic, indifferent, ignorant of the practical value of membership in medical societies, which fact is undoubtedly responsible for their unfortunate condition? While recognizing that knowledge is power, we sit down comparatively comfortable and contented, refusing to exert ourselves in the way that demands and secures recognition of our rights, of our worth and of our power. How may we change this order of things? Changed it must be, and already it is becoming different in some sections of the United States. A new era in medicine is unquestionably ours; and a new history is being written for us. Evolution is becoming revolution in medical affairs, at least in our own state and a few others, and it is to be hoped and expected that the work of progress that has recently been started will sweep the country from ocean to ocean and from the lakes to the very gulf.

While we are looking for the millenium, it can not be denied that the ideal in medicine is far from the real—nor, again, that the real may not be made to approach a little more closely the ideal. We may say that a physician's work or life may be viewed from three aspects: first, the scientific or purely professional; second, the social or companionable mingling together; and third, the business side, which looks after the material gain that is so necessary and utilitarian. When these three qualifications are properly combined, we have what may be considered an ideal medical character. The question, therefore, is, how may we obtain, even approximately, this desirable state? At the last meeting of our Ohio State Medical Association a new constitution and by-laws were unanimously adopted, and if Cincinnati and Hamilton County are to be represented, the Academy of Medicine of Cincinnati must become "a component society" of the state association, representing and including all the eligible physicians of the county.

Among other things that were done at this meeting, was the election of what is called a council, really a committee, composed of ten members of the association, selected from different parts of the state, whose duty it is to go about organizing and reorganizing medical societies in the different counties and looking after the interests of the profession in every possible manner. Greatness has been thrust on me, great work at least, in that I am one of the unfortunates selected to help perform this important duty. While I find it somewhat arduous, it is also very pleasant, and I find myself taking a very great interest because of the many good results being observed. My district is composed of nine counties in southwestern Ohio and I am taking much pleasure in assisting to form and increase the interest in these medical societies.

As the most of you know, an invitation from me as state councilor has been extended to you of Cincinnati to go to these outside county medical societies and render your quota of assistance. Of two hundred of these invitations sent among you, I have received favorable replies from about one hundred. This list will be sent to the secretaries of the various county societies of Ohio and to the nearby counties of Indiana and Kentucky; from it selections will be made by the secretaries and invitations will be sent to you to read papers or make addresses before these societies. Thus you will be able to assist in "organizing component societies and increasing the zeal of their members," as are the directions from the state association to its council. It has long since become a maxim that in union there is strength; that individual effort avails but little in any great movement. But how are we to accomplish this union of strength, this union for greatest influence, this union for greatest good to the medical profession and the people in general? A movement has already been begun and is spreading from county to county and from state to state. The great American Medical Association has already formulated a plan that is being adopted by the several state societies; and it is the furthering of this idea, together with the consideration of a revision of our own academy constitution that is the special subject for this evening. No one in medicine is too good, or too great, or too busy; too old or too young, or too little or too big, or too lazy to be allowed to escape duty in the future. On your program will be seen that a few only of the many features of organization are to be considered this evening. Any one of them could easily take an entire evening, but our object is to have some of the essentials lightly touched on, for a few minutes each, hoping that the opinions of the speakers may assist in awakening interest in society work and in obtaining promises from all present to lend a helping hand in organization.

Medical Organization.

Dr. Charles A. L. Reed called attention to the condition of medical organization in the United States at the time of his election to the presidency of the American Medical Association in 1900. Aside from the national body there were then local, county, district and state societies, the district societies in many instances embracing areas that varied in extent from several counties to several states. The membership in one of these bodies was frequently made up to an important degree of the members of some other organization within the same territorial limits. This circumstance was of no importance so long as the respective local bodies devoted themselves to social and scientific proceedings, but it became a matter of very great importance when it came to the question of pro rata representation for legislative purposes in both the various state societies and in the American Medical Association. Thus it not infrequently happened that the profession, in certain parts

of the country, duplicated its representation in the various delegate bodies, while it utterly failed to secure concert of action in important matters pending before various state legislatures, or for that matter before Congress.

This state of affairs had become peculiarly embarrassing to the American Medical Association. This body, organized on the delegate plan in 1847, as an unincorporated and purely voluntary organization, at first, and for several years received the delegates from practically every possible source, including the public services, medical societies, medical colleges, hospitals and lunatic asylums. This wide-open policy was soon found to be impracticable, and there was a gradual restriction of the right to send delegates, until, finally, no professional bodies except affiliated medical societies were granted the right of representation. There was but very little restriction, furthermore, in granting affiliation to medical societies. Many of the district societies, especially multi-state societies, had been very properly cut out, the only condition imposed on the remaining societies being that prescribed by the resolution of 1855. This resolution provided that no medical body should be recognized as an affiliated body that had not previously adopted the Code of Ethics of the American Medical Association. It subsequently appeared without further recorded action as Article IX of the old constitution, and was at the time of its adoption aimed at the Ohio State Medical Association.

Dr. Reed then discussed the code question very fully, mentioned the action taken in 1855, when a resolution was adopted, requiring all affiliated societies to adopt the code, and the rescinding of this action at St. Paul in 1901 by omitting this requirement in the new constitution and by-laws, etc.

The Importance of County Medical Societies.

DR. HORACE BONNER urged that, of medical societies, the most important is the county society. "Leaving out of account its importance as a unit in the scheme of organization, still it is the most important medical society in the land. It is accessible to the whole profession, even to the humblest member. All can share its advantages and it is, for the large majority, the only society. It is their post-graduate school and the only one they have, for comparatively few can attend the state societies or the American Medical Association." In county societies men "read and discuss papers, exchange experiences, comment on the lessons these teach, receive and give encouragement and have a short but enjoyable relaxation from the cares and worry of everyday life."

"These societies are good, indifferent or poor, just as the members make them, none is so good that it might not be made much better, none so poor that it is not very much better than no society. Their great weakness is their selfishness. They exist for their own members alone. They do not help their weak neighbors in adjoining counties and they have little or no public influence." The conditions in the state and the conditions in the national organization demand that medical men get together. "Individual effort is vain." "The whole plan is successful or falls to the ground just as we succeed in making the county society efficient." In it discussion is initiated. From it go the instructed delegates to the state association, and from the state association, likewise, the representatives are chosen to the American Medical Association.

The consummation of the desired organization will be complete and will be ideal only when the county societies "include 'every reputable and legally qualified physician in each county who does not practice or claim to practice sectarian medicine.'" "The county society is supreme." Membership in it establishes standing as a physician. "I don't care what the code of the American Medical Association may say, the code of the profession is going to be that 'a physician must be, in all things, a gentleman according to the standards of society and, therefore, one who is honest in his dealings with his patients and with his fellows.'"

"I am glad the word 'regular' does not occur in the constitution or by-laws of either the state or county. Hereafter we shall be 'physicians.'"

Medical Ethics.

DR. P. S. CONNOR stated that medical men may be classified under three heads: Those who need no code of ethics, those who will obey no code of ethics, and those who can be influenced toward the right by the code of ethics. The latter class constitutes no small number. The only objection to doing away with the code of ethics is that it opens the door to those who will confine themselves to one dogma or one line of medicine. There is not the slightest difficulty in the code being carried out as far as we are concerned. If there were no sectarian doctrines preached and no effort made to get business through the influence that we attach to sectarianism of one sort or another, we would need no code of ethics.

Medical Legislation.

DR. N. P. DANDRIDGE stated that there are three distinct sets of organizations which are becoming more and more powerful by means of association: namely, medical societies; second, medical colleges, which have existed longer than state societies and only recently have come into anything like a combined body; and third, the boards of state examiners. While these three bodies should, as far as possible, work together, yet in many lines they are antagonistic, and in order to do their work properly they must be antagonistic. Yet he thought that the tendency of state boards was to become yearly more and more arbitrary in their decisions, and that many facts of importance to the medical colleges and to the profession at large were kept secret for a longer time than was consistent with progress or good judgment. He also thought that the requirements of a candidate for a medical profession or a legal career or any other profession should be under the supervision of one board, as it is now in the state of New York. On the whole, he thought that attempts at medical legislation, at least as far as Ohio was concerned, had resulted in unmixed good, and no one, he thought, not even those connected with medical colleges, who were the greatest sufferers, would be willing to return to the days of chaos previous to medical registration and later of state board examination. As far as the personnel of the Ohio State Board was concerned, he thought that the selection had been most happy; certainly the members of the board who were not of the regular profession, so-called, had contributed in no small measure to the enactment and carrying out of many of the most important measures inaugurated by the board.

Social Needs of the Physician.

DR. E. W. MITCHELL thought that the physician should labor less hours and so have more time to mingle with his fellows and thus get out of the morbid rut into which his profession is apt to throw him. To do this the fees of the physician need to be radically increased, as he is now working in the large majority of cases for far less than he ought to receive. One of the chief inducements for Dr. Mitchell to attend the local medical society, he said—only less in importance than the professional aspect—was the social time that he was able to enjoy with his brother physicians. This was also true in attendance at the larger meetings held at a distance.

The Doctor in Politics.

DR. LOUIS SCHWAB stated that medical men organized in the past for mutual improvement alone—to exchange experiences with one another. The medical society in the past has been the admiration of the public because there has never been in it a breath of either religion or politics. But the physician is a citizen and even he can raise his voice for what he feels will be for the good of the people. He will always be granted a hearing and with a respectfulness that is given only to one of honest intention. Of late years many a medical man has devoted time to public affairs. When he is "chosen to public office he feels that he is not only responsible to the people, but that he is answerable to his craft for all his acts." Medical men can be found in Congress, in state offices, occasionally in the governor's chair and in prominent positions of many kinds without in the least detracting from or interfering with their reputation as physicians. Public service will demonstrate to many a physician the contracted life he was living and make him a more able man to practice his profession. "If the doctor in politics will practice the same self-denial that he does in his profession, public faith in him will be

as strong and tender as that which he is made to feel at every bedside which he visits."

Commercialism in Medicine.

DR. THAD. A. REAMY was very much inclined to defend the young physician who attended cases for a lower fee than his older competitor, though he saw no reason why a young physician should not charge the same as an older one for the same service, provided that the young physician had, by virtue of his previous training and experience, obtained a good and recognized standing in his profession. Dr. Reamy was emphatic in his condemnation of division of fees.

Fees, Bills, Collections and Dead Beats.

DR. MAGNUS A. TATE spoke from an experience of twenty-four years with fees and collections, twelve years in the practice of medicine and twelve as a boy and young man, collecting for his father. Many a physician who has means outside his practice fails altogether to grasp the problem of collections or to sympathize with the importance of this point to the physician as a class. "As a boy I became impressed with the following: Gratitude existed only in those who paid their bills and the one who penned the following had some experience:

> The danger o'er, the patient is delighted,
> God is forgotten and the doctor is slighted.

From his experience Dr. Tate has found the following points of value: "Charge reasonable fees, smaller to the poor, but never overcharge the rich." The physician needs the influence of the well-to-do. He must be fair and honest with them, and they will return it with interest. "Surgical operations and obstetric fees are entirely governed by the character of the case and the ability of the patient to pay." The sum charged by the general practitioner in obstetric cases is ludicrous. It is the most poorly paid of all work in the practice of medicine. Dr. Tate can see no remedy for this evil at the present. He usually makes a charge for telephone advice. If he finds a crank who objects to paying for simple advice where no medicine is given, he adds medicine. Charges should be increased for night calls, contagious cases, Sunday calls and first visits. The contract doctors are governed by but one object, which is "self." Watch them through life and see if this diagnosis is not correct. They are making medical paupers out of thousands and doing irreparable harm. It is no wonder that insurance companies have inaugurated their liberal method of dealing with physicians on what they term business methods. Dr. Tate gave some examples of this abuse.

Members of the profession are seriously at fault in not telling the truth as to their revenue. "It is a sad commentary on the practice of medicine and truth to hear of the marvelous sum that Dr. So-and-So is making a year, and you know otherwise." This practice does two things: "1. It makes many a young man or woman enter the profession who is in no way fitted to enter, and 2, it keeps the impression alive that physicians are rich and do not need any money and consequently leads to great difficulty in the collection of our accounts."

Concerning collections, Dr. Tate urged that the medical profession shows a serious lack of business principle. Many a physician tells his patient that there is no hurry about payment. Many a physician has not the courage to ask what is his just dues. When a bill has waited six months, perhaps the patient is dead, perhaps he has removed and you can not find him, or perhaps he has gone to another physician because he owes you, which gives the impression that he was dissatisfied with you, perhaps he has forgotten just what you did for him and refuses to pay it in whole or in part. Dr. Tate's practice has been to send out bills the first of the month following services rendered, for the following reasons: 1. If there is any misunderstanding, memory is fresh and can straighten out the difficulty. 2. The patient's address is probably known. 3. The patient has not lost all the gratitude born in him while he was sick.

Dr. Tate urges the prosecution of dead beats, but he wishes to insist that there is a distinct line to be drawn between the dead beat and the poor man or woman who can not pay. "Charity is the sweetest morsel that one can taste; its flavor is delicious when it is given to the unfortunate and needy."

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Menstrual Pains in Virgins.

Dr. Touvenaint, in *Klin. Ther. Woch.*, recommends that hot applications be applied to the abdomen to relieve the pains and produce rest. If the pains are very violent an enema containing fifteen minims of tincture of opium or fifteen to forty-five grains (1.-3.) of chloral hydrate should be administered. The following combination may be used as a substitute for one of the foregoing:

℞.	Tinct. opii	gtt. x	65
	Pulv. camphoræ	gr. iii	20
	Yolk of 1 egg.		
	Aq. destil.	ʒiv	120
M.	Sig.: As an enema; or:		
℞.	Ext. cannabis ind.		
	Ext. belladonnæ, āā	gr. i	06
	Ol. theobrom. q. s.		

M. Fiat suppos. No. i. Sig.: Two or three daily.

Bronchitis Complicating Diseases of the Heart, Lungs and Kidneys.

The treatment of this form of bronchitis, according to I. N. Danforth, in Textbook of Applied Ther., should begin with the treatment of the condition that precedes and causes it. Elderly individuals, however, are improved by the administration of potassium iodid. The following formula is recommended by the author:

℞.	Pot. iodidi	ʒiiss	10
	Syr. picis liq.	ʒiv	15
	Syr. pulveris doveri	ʒi	30
	Syr. tolutani, q. s. ad	ʒiv	120

M. Sig.: One teaspoonful four times a day.

Stimulating expectorants are rarely needed in this form of bronchitis, but the author recommends small doses of aromatic balsams combined with a mild anodyne if the cough is troublesome, as follows:

℞.	Terebinthinæ canad.		
	Pulv. ipecac. et opii, āā	ʒi	4
	Pulv. acaciæ q. s.		

M. Ft. capsulæ No. xx. Sig.: One every three or four hours; or:

℞.	Copaibæ		
	Camph. monobrom., āā	ʒi	4
	Pulv. acaciæ q. s.		

M. Fiant cap. No. xx. Sig.: One three or four times a day; or:

℞.	Olei santali	ʒii	8
	Tinct. opii camph.	ʒi	30
	Sacchari albi		
	Acaciæ, āā, q. s.		
	Aq. anisi q. s. ad	ʒiv	120

M. Fiat emulsio. Sig.: One teaspoonful three or four times a day.

Technic of Hypodermoclysis.

Jos. Byrne, in *Merck's Archives*, recommends, in the administration of normal saline solution, that after preparing the patient, the fountain syringe be filled with the solution at a temperature of 102 F. to 105 F., to which a coarse but finely-pointed needle be attached and the syringe suspended six or eight feet above the patient. The physician, after thoroughly sterilizing his hands, should hold the needle and allow the flow to start before introducing it, in order to remove the air and cold fluid from the tube. With the other hand a fold of the skin in the axilla or over the abdomen should be grasped between the thumb and the finger and elevated similarly to the methods employed in giving an ordinary hypodermic injection. The needle should be pushed into the subcutaneous tissue, getting well beneath the skin, but not penetrating the muscular tissue beneath. The needle then can be freely moved about under the skin when the clamp may be loosened and the solution allowed to flow. Six to eight ounces will be all that

can be injected at one point; the needle may be removed and an injection made at another point. This may be repeated until the requisite amount is injected, which may range from one to three pints. If pain occurs during the operation gentle massage may be given to facilitate absorption. The addition of small quantities of glycerin or carbolic acid is said to relieve pain, yet the author does not advise their use. With thorough aseptic procedures no dangers should arise from this procedure.

Administration of Creosote Carbonate.

In order to overcome the difficulty encountered by some patients in taking creosote, J. J. Stoll of Chicago recommends that it be prescribed in the form of an emulsion, as follows:

℞.	Creosoti carb.	℥ii	8
	Ext. malti	℥iv	15
	Glycerini q. s. ad	℥iii	90

M. Fiat emulsio. Sig.: One teaspoonful after each meal.

Acute Pelvic Inflammation.

E. C. Hill, in *Med. Standard*, recommends in the treatment of acute pelvic inflammations, from whatever cause, that the patient be placed in a comfortable posture; sometimes elevating the foot of the bed gives great relief. The administration of morphin or opium in sufficient doses, which may be given per rectum; absorbent cotton saturated with equal parts of tincture of belladonna and glycerin applied hot and covered with a rubber cloth. Ten or fifteen grains of quinin should be given on the first days of the disease.

A small amount of cold water may be given frequently to relieve the thirst. If the lower bowel is loaded, employ a rectal injection composed of the following:

℞.	Magnes. sulph.	℥iii	90
	Glycerin		
	Aquæ, āā	℥ii	60

M. Sig.: As an enema, to be repeated as necessary.

Sodium phosphato, dram one-half (2.00) then should be given and repeated every three or four hours.

When the acute symptoms have subsided and there is no evidence of pus or serum, small blisters should be applied repeatedly to the iliac regions (one on each side) or paint the roof of the pelvis with tincture of iodin, or keep up counter irritation with the following solution:

℞.	Olei tiglii	℥i	4
	Etheris sulphurici	℥ii	8
	Tinct. iodi	℥iii	12

M. Sig.: Paint over the lower abdomen and repeat when the eruption disappears. Nourishing food, quinin, ferri iodid, potassium iodid, ferric chlorid and other tonics may be prescribed. Avoid exercise which excites pain. Promote absorption and lessen adhesions by pelvic massage.

Menthol for Local Application.

The following combination, containing menthol, is recommended by Kuehl in *West. Druggist*, for local application as a liniment:

℞.	Menthol	gr. xv	1
	Spts. chloroformi	℥i	4
	Spts. camphoræ	℥iiss	10
	Spts. saponis	℥i	30
	Olei gaultheriæ	℥ss	2

M. Sig.: Apply locally.

Putting Drops Into the Eye.

Sharp, according to an abstract in the *Ind. Med., Jour.*, gives the following suggestions and directions for dropping solutions into the eye: Never apply the drops directly to the cornea, nor should the dropper be brought down in front of the eye as the patient will close the eye reflexly. The dropper should be brought from below upward and to the outer canthus. Have the patient turn the eye upward and at the same time gently evert the lower lid, and while it is in that position place one or two drops on the conjunctiva of the everted lid. Not more than two drops should be put in at one time as the sac is not capable of handling more. The patient should then be directed to look down, at the same time holding the lower lid until the upper one comes in contact with it. In this way none of the solution will drop down on the cheek. Care should be taken that the dropper does not touch the eye anywhere as it may infect the eye or in turn become infected by the eye and will infect the medicine when replaced. It is well to boil the dropper before using it.

Chordee.

The following outline of treatment is recommended by Bjorkman in *Merck's Archives* in the treatment of chordee. Cold applications should be applied to the perineum or to the penis itself or hot sitz baths or leeches applied to the perineum. Keep the patient in bed on a light diet and keep the bowels well open. If abscess formation takes place a free external incision should be made in order to prevent urethral fistula.

The following internal treatment is recommended by the author:

℞.	Lupulini	gr. xv	1
	Camphoræ	gr. iiss	15

M. Ft. pil. No. x. Sig.: One pill every hour until the effects are produced; or:

℞.	Camph. monobrom.	gr. xviii	1 20
	Ext. hyoscyami		
	Opii depurati, āā	gr. ix	60
	Ext. lupulini q. s.		

M. Ft. pil. No. xv. Sig.: One pill four times a day; or:

℞.	Ext. opii	gr. i	06
	Ext. hyoscyami	gr. ii	12
	Lupulini	gr. ix	60
	Ol. theobrom.		

M. Ft. suppos. No. vi. Sig.: One to be inserted into the rectum two or three times a day; or:

℞.	Chloralis hyd.		
	Potass. brom., āā	℥iss	6
	Syr. aurantii	℥vi	24
	Aq. destil. q. s. ad	℥iii	90

M. Sig.: Two tablespoonfuls at bedtime for the nervousness and insomnia.

As an ointment to be applied locally the following is recommended:

℞.	Ext. hyoscyami	gr. xv	1
	Lanolini	℥ii	8
	Vaselini	gr. xxx	2

M. Fiat unguentum. Sig.: To be applied locally.

Medicolegal.

Demonstration of Extent of Incapacity from Injuries.—In the personal injury case of Clark vs. the Brooklyn Heights Railroad Company, the party suing was permitted, for the purpose of showing the extent of his injuries, to attempt, in the presence of the jury, to drink a glass of water and to write his name. The Second Appellate Division of Supreme Court of New York holds that there was no error in permitting these demonstrations of the alleged inability, but that such evidence was admissible within the fair discretion of the trial court. It says that the injured person could certainly be allowed to testify that since the injury he had not been able to write without experiencing a tremor of the hand, or to drink a glass of water without similar inconvenience. No good reason is perceived why he may not be allowed to illustrate the extent of this incapacity as well as to state it in words. Deception, of course, is possible in such an illustration, but it is equally possible in the oral statement. In either case, the jury are to judge of the credibility of the witness.

Physician May Testify as to Competency of Nurse.—The First Appellate Division of the Supreme Court of New York holds, in Ward vs. St. Vincent's Hospital of the City of New York, that a physician who has had daily opportunity of observing the work done by a nurse—who has seen how she has done it—is qualified to say whether, in his opinion, she was a skilful and competent nurse. It says that the necessity for opinion evidence arises whenever it is impossible to state to the jury all of the facts which are essential to enable it to form an accurate judgment. Whether or not one be a skilful and competent nurse necessarily depends on many facts, all of which, from the very nature of things, it is impossible to lay before a jury, and for that reason a physi-

cian who has the personal charge of a patient, and who daily sees the manner in which a nurse performs her work over that patient, is competent to express an opinion. Furthermore, while it holds that it was for the jury to say whether, on the facts presented, one of the sisters of charity in charge of a charitable institution acted within the scope of her authority in making an alleged contract to furnish the services of a skilled and experienced nurse to the party suing while she was undergoing a surgical operation and recovering therefrom in such institution, the court holds that it was error to refuse an instruction that if the jury found, as a fact, that the party received no more than the personal assurance of the sister, then there was no contract on behalf of the institution.

What Constitutes Total and Permanent Disability.—In the case of Monahan vs. the Supreme Lodge of the Order of Columbian Knights one of the questions was the construction to be put on a by-law, which provided that whenever a member in good standing became "totally and permanently disabled, by reason of accident or disease, from following any occupation whatever," he might be paid a certain sum of money out of the funds of the order. The Supreme Court of Minnesota holds that, in order to recover under this section, it is not necessary that a member shall be disabled to the extent that he has not sufficient physical power to follow some easy occupation, and to perform some slight service, although under great disadvantage and while suffering great bodily pain. It says that, on the subject of proper construction, it will not undertake to improve on the apt language of the trial judge that "the words 'following any occupation' mean something more than the doing of one or more acts pertaining thereto. They involve the idea of continuity, and involve, also, the doing of all those things which are an essential part of the work or business in which a party is engaged." The language must have a practical and rational construction. It is difficult to conceive of a case where a man would be so completely disabled as to prevent his engaging in any kind of occupation. The party suing was shown to be substantially unable "to follow any occupation, because he was not able to do all of the essential acts necessary to be done in the prosecution of an occupation."

Marriage May Be Annulled for Venereal Disease.—In the case of Svenson vs. Svenson the Second Appellate Division of the Supreme Court of New York approaches as an entirely new question in that state the one of whether a marriage may be annulled for the fraudulent concealment by one of the contracting parties of the existence at the time of the marriage of a chronic and contagious venereal disease. It pronounces an unquestionably sound proposition, the general one that ill health, although concealed, or even although the condition has been misrepresented, will not of itself justify annulment. In the absence of binding and explicit authority, however, it says that it would be unwilling to assert a doctrine which would require a court of equity to hold that a man who finds a woman whom he has innocently married afflicted with venereal disease, and who, therefore, refuses to consummate the contract, may not procure a decree annuling the marriage because of the fraud involved in the existence of the condition and its concealment. Such a condition would seem to be amply sufficient to justify a finding that the afflicted party was physically incapable at the time of meeting the obligations of the relation. The reasoning which refuses relief in the case of ordinary ill health has no application to a disease which involves disgrace in the contraction, contagion in marital association, probably injury to offspring, and which, from its secret and shameful nature, denies to the innocent and unsuspecting the protection of foreknowledge. But in all cases of this character it is of the first importance that the application for judicial relief should be of absolute good faith and free from the suspicion of collusion.

Opinion of Attending Physician Evidence as to Injury.—The Supreme Court of Minnesota holds, in the personal injury case of Skelton vs. the St. Paul City Railway Company, that it is proper to allow a physician to give the result of information derived by him in the treatment of a patient, when being examined as an expert. In this case a physician, who was attending the party suing during her illness, was permitted to state, in describing her symptoms, that she had suffered from headaches. The record showed that such knowledge was derived from information received from the party during the course of professional treatment, which was obviously necessary to enable the medical attendant to prescribe for his patient. The same physician also testified as to the probable continuance of her malady, and expressed his opinion on the question whether her injured limb would ever regain its normal condition. This was after he had given a somewhat extended clinical history of her treatment, and was based on the information he had derived during the course of his professional attendance. The Supreme Court holds that this was proper. The opinions of a professional expert in such matters, it says, are not required to be based on hypothetical questions embodying a description of the physical condition of a person, but may be formed on knowledge of the injuries derived at the bedside, or from evidence in court. Quite like this is the decision of the Supreme Court of South Carolina in the personal injury case of Oliver vs. the Columbia, Newberry & Laurens Railroad Company. It says that the medical expert makes his diagnosis of an ailment from the symptoms discovered by his skill and from other symptoms gathered from the statements as to her present condition made to him by the patient while under examination. From these symptoms, thus discovered, he determines what "is the matter" with his patient, and the jury may have this conclusion expressed to them as the opinion of an expert witness. Besides this, the court holds that, in a personal injury case, testimony of the amount paid for medical attention is admissible for the purpose of throwing light on the extent of the injuries, just as testimony as to the length of time the patient was confined to her bed would be.

6 *Care of the Eyes of School Children. Linn Emerson.
7 Vital Statistics: A Plea for Actuarial Administration and Control of the Great Resources of Preventive Medicine. (Continued.) John S. Fulton.

1. **Liver Diseases.**—Stockton states that in this paper he does not attempt to treat the differential diagnosis thoroughly, but to point out certain distinctive characteristics in the familiar diseases of the liver, commencing with ordinary hepatic cirrhosis and so-called syphilitic cirrhosis. He finds this sometimes difficult, but remarks that in the syphilitic form the liver is large, frequently bosselated and of irregular contour and is sometimes accompanied by a friction rub. A history of syphilis and the therapeutic test are important points in the diagnosis. An apparent cure will occur in a large proportion of cases with syphilis. Sometimes the disease is too far advanced for such results and in others there may be a relapse. The diagnostic points between cholelithiasis and cancer of the liver are also discussed. He remarks that when cancer affects the liver it is usually secondary, and some information may be gained by locating the primary growth. There is a lack of history of characteristic hepatic colic unless cholelithiasis also exists. The presence of jaundice, with enlargement of the gall bladder, suggests cancer, while the history of gallstone and the gall bladder not palpable, indicates stone in the common duct. This is practically Courvoisier's law. Other points are also noted. Abscess of the liver may be confused with cholecystitis and angiocholitis. The history of the

case should be of assistance, and frequently when we suspect abscess puncture may be resorted to. He has seen no bad effects from puncture, though it may be difficult to find a small abscess. Lastly he considers sclerosis of the liver following chronic biliary obstruction and the so-called Hanot's cirrhosis of the liver, which he holds is a disease *sui generis*, usually seen in the young, without alcoholism, often acute in the beginning, though the disease is usually protracted. In the onset there is pain, often severe in the region of the liver, and probably a temporary elevation of temperature. The patient is found to be moderately jaundiced. The liver is very large, as is also the spleen, and pigmentation of the skin may be present over and beyond that occasioned by jaundice. The pain may be intermittent and the patient may often be for months exempt from all symptoms. Eventually, though perhaps not for five or ten years, jaundice appears, temperature rises and the patient dies from icterus gravis.

2. **Streptococci in Milk.**—The importance of streptococci in milk is insisted on by Reed and Ward, who find that infectious mammitis in the cow may have no specific symptoms. They remark, in conclusion, that the classification of streptococci is still in an unsettled state. The common prevalence of mammitis in the cow constitutes an important source of streptococci in market milk. The insidious onset of the disease is responsible for this being often innocently sold, and the common method of milk handling in stables deserves mention. The milk, after drawing, is generally poured in a common receptacle with other milk, and if the existence of udder inflammation is shown by curd-like masses on the sides of the strainer, ignorance or greed may prevent the proper rejection of the infected milk. The presence of streptococci must be regarded as a matter of danger. To understand the conditions under which these streptococci harbored in the healthy udder may become virulent will require a further study of the pathology of mammitis.

3. **Tuberculosis.**—McCaskey's article is largely on the diagnostic and therapeutic use of tuberculin. He believes in both. He also points out the diagnostic value of superficial chest pain, and gives schematic illustrations showing the reflex routes by which it may occur.

4. **Altitude in Heart Disease.**—Pearce discusses the effects of increase of altitude on the nervous cardiac symptoms. Ordinarily up to 5,000 feet or more no disturbance is caused in the normal heart. As we go up higher, however, there is a decided disturbance. In functional nervous disease he would advise against stimulating climates and altitudes over 2,000 feet as well as enervating climates at the lower levels. The matter of dryness of climate has something to do with the effect, and may be considered favorable.

5. **Nitrous Oxid Anesthesia.**—Galloway gives the results of 250 different cases where nitrous oxid was used either alone or as a preliminary to ether anesthesia. He considers that while there is no ideal anesthetic this comes as near to it as any. It does not terrify the patient as do ether or chloroform, produces no distressing symptoms and is so rapid that there is little time for the patient to become frightened. Less anesthetic is used, and, therefore, recovery takes place quicker, and the after-effects are correspondingly less.

6. **The Eyes of School Children.**—After noting the possible troubles from neglect of the condition of the eyes in school children, Emerson suggests examination to ascertain the following facts in each individual pupil:

1. Does the child fail to read a majority of the letters on the XX (20) line of the Snellen test types with either eye?
2. Do the eyes and head habitually grow weary and painful after study?
3. Are the lids or eyes habitually inflamed?
4. Is the child cross-eyed, or do the eyes diverge?

On an affirmative answer to any of these questions a letter of warning should be sent to the parents.

Boston Medical and Surgical Journal.

8 *Irrigation in Acute Urethritis. Arthur L. Chute.
9 *A Report of a Case of Multiple Neuritis of Questionable Origin. Arthur W. Marsh. With Remarks by George C. Smith.
10 *Sub-dural Cervical Carcinoma, Secondary to Carcinoma of the Breast. E. W. Taylor and G. A. Waterman.
11 A Case of Pneumonia, with Relapse. A. Lawrence Mason.
12 *A Form of Pressure Anemia of the Uvula Which May be Mistaken for Membrane. W. P. Coues.
13 *Antisepsis of the Clinical Thermometer. William H. Devine.

8. **Irrigation in Acute Urethritis.**—Chute advocates the use of irrigation in this condition, holding that while it is at times and in occasional instances disappointing, it gives in acute urethritis the best individual and general results. It also offers the patient the greatest immediate comfort and safety, and as prompt if not more prompt recovery takes place than when other means are employed. Recovery is also more certain and the probability of latent complications diminished.

9. **Multiple Neuritis.**—Marsh details a case in a woman aged 52 and considers the cause to have been tubercular. The paper ends with some remarks by Dr. George C. Smith, who also analyzes the symptoms, finding the balance of argument in favor of the tubercular origin.

10. **Subdural Cervical Carcinoma.**—Taylor and Waterman report a case with microscopic examination of the tumor. The special points of importance to which they call attention are the growth of long standing in the immediate neighborhood, with slight involvement of the cord, limitation of the new growth essentially to the subdural space, extensive motor and sensory paralysis from involvement of the nerve-roots alone, and absence of pain attributable to invasion of sensory roots.

12. **Pressure Anemia of the Uvula.**—Coues calls attention to a condition which he has observed several times, consisting in a white spot seen on separating the tonsils from the uvula, which, on careful examination, is seen to be exactly at the point of impaction of tonsil and uvula; is not raised above the surface and does not bleed when touched. He thinks it occurs in streptococcus infection of the throat, when a non-diphtheritic membrane is perfectly possible.

13. **Antisepsis of the Clinical Thermometer.**—This subject is, according to Devine, too much neglected in text-books. The importance of cleaning the instrument is perhaps considered sufficiently evident. He thinks the best method to keep it free from germs is to keep it in an antiseptic solution when not in use and that no one should ever use a thermometer to take the temperature in the mouth or rectum without being absolutely certain of its being perfectly sterile. The best methods for eliminating transmission of disease, he thinks, are: 1. Separate instrument for each patient. 2. The hospital method of keeping the thermometer immersed in antiseptic solution, when not in use, and 3, keeping in the thermometer case a solution of bichlorid and alcohol (1-5000 to 1-2000).

Medical Record, New York.

14 *A Résumé of Some Recent Researches Relating to Cytolysis and Immunity. T. Mitchell Prudden.
15 *The Problem of Epilepsy: Some Suggestions for Its Solution. L. Pierce Clark and Thomas P. Prout.
16 *The Radical Cure of Inguinal Hernia with Local Anesthesia. J. A. Bodine.

14. **Immunity.**—Prudden's paper is a review of theories and facts relating to cytolysis and immunity that does not lend itself to abstracting. He holds there is abundant ground for the belief that the protective agents invoked in natural and artificial immunization are simply those made use of by the body in its normal metabolism, exaggerated and diverted to different ends, in the face of emergencies, but involving no new physiologic capacities.

15. **Epilepsy.**—Clark and Prout consider epilepsy as due to a toxemia involving particularly the cervical cortex, and they summarize that "epilepsy is a disease resulting in diffuse and profound cortical degeneration; a highly complex sensory motor phenomenon, primarily sensory with a motor expression. The lesions are swollen nucleus, destruction of the nuclear membrane and intranuclear network, easy abstraction of the nucleolus by the knife, diffuse chromatolysis and other protoplasmic changes in the cell tending to its ultimate disappearance as a biologic unit and its replacement by a gliosis. The lesions are induced by a toxic or autotoxic agent operating on an organic anomaly of the cerebral cortex which forms the predisposition."

Medical News, New York.

February 14.

17 *A Study of a Bacillus Resembling the Bacillus of Shiga, from a Case of Fatal Diarrhea in a Child; with Remarks on the Recognition of Dysentery, Typhoid and Allied Bacilli. Philip Hanson Hiss, Jr., and F. F. Russell.
18 *Post-Diphtheritic Ocular Paralysis. P. N. K. Schwenk.
19 *Post-Diphtheritic Paralysis Affecting the General Nervous System. Luther C. Peter.
20 *Post-Diphtheritic Paralysis Affecting the Ear and Throat. Carle L. Felt.
21 *Laboratory Aids in the Diagnosis of Typhoid Fever. E. E. Smith.
22 *The Influence of Sodium Chlorid upon Gastric Secretion. Lyman B. Stookey.

17. **Bacillus Y.**—Hiss and Russell have isolated an organism from the feces of a case of fatal diarrhea in an infant which has a close resemblance to the bacillus of Shiga, but presents certain differences. It agglutinates in high dilutions with the serum from dysentery patients and animals immunized with Shiga bacilli. Formerly it could not have been differentiated by valid culture tests from the bacillus of Shiga, and, the mannite test being unknown, might easily have been confounded with Shiga's micro-organism unless its agglutinating reactions had been carefully studied in such a serum as that from typhoid immune animals, or from the normal beef, in neither of which the true Shiga bacillus, according to their tests, agglutinates in appreciable dilutions. It is also closely related to the *Bacillus typhosus*, both in agglutinating reactions and in the usually-observed cultural characters, but can be separated from it by the absence of motility and by its reactions in the maltose and dextrin media employed. It apparently differs from all hitherto described dysentery-like or pseudo-dysentery bacilli in its agglutination in high dilutions of dysentery serum, an agglutination in some instances more marked than that shown by the true Shiga bacillus. Its etiologic significance is not fully determined, but its close physiologic connection with the dysentery bacillus on one side and typhoid on the other, make it not improbable that further research will show it to be associated etiologically with certain diarrheic or dysenteric attacks. They recognize three groups of organisms, one represented by the true Shiga bacillus fermenting dextrose and some other monosaccharids, one by the organism Y, fermenting dextrose (monosaccharids) and the alcohol mannite, and finally a group represented by the more active fermenters—Flexner's Manila cultures and the culture "Baltimore"—organisms which split dextrose, mannite, maltose, dextrin and saccharose with the production of acid, as indicated by the reddening and coagulation of the serum-water sugar media. Their study, they hold, shows the inadvisability of relying on superficial characters or agglutination tests alone in the identification of an organism, or on the serum tests in the determination of the special character of a disease. They suggest that organisms differing from the true Shiga bacillus have been isolated and confounded with this organism.

18. **Post-Diphtheritic Ocular Paralysis.**—This condition is described by Schwenk, who holds that the generally active pupils, the frequency of paresis rather than paralysis and the bilateral character of the lesions can not be accounted for on any other theory than the peripheral one in these affections.

19. **Post-Diphtheritic Paralysis Affecting the General Nervous System.**—Peter considers this condition a toxemia which may affect the nerves generally or confine itself more or less to special nerves. Cardiac failure in diphtheria, he thinks, is possibly due to functional disorders of the vagi, and perhaps organic changes in the nerve structure. He believes in the use of antitoxin as one of the best measures, with rest, which is absolutely imperative, both during and after the attack. Massage and galvanism may help, and iron and strychnia be of some value.

20. **Post-Diphtheritic Paralysis of the Ear and Throat.**—Felt describes the symptoms of these conditions, which are generally curable. The use of antitoxin as now generally conceded, prevents and does not cause diphtheritic paralysis. The ideal way is to use it early, with rest in bed and a simple diet; these, with attention to the excretions, compose the fundamental principles of treatment. Strychnin should be administered throughout the course of the disease, while electricity, tonics, baths and massage are valuable adjuvants.

21. **Value of Laboratory Methods in Typhoid.**—Smith does not consider that the laboratory affords aid that is certain for all time and in all cases, but it does aid the clinician in the diagnosis of characteristic morbid products, identification of organisms and of the agglutinins. The diazo test he does not consider as valuable as some have claimed, but it is well worth observing. There are some inconveniences in isolating the organism from the blood or rose spots, but this method is worthy of more general attention than it receives. A positive Widal reaction is of great value; the embarrassment is in the negative one. In conclusion he calls attention to the value of the laboratory in establishing the diagnosis of other conditions where typhoid is suspected, such as the malarial parasites in the blood, the blood characteristics of pneumonia, the organism of tuberculosis and the condition of the blood cells in certain forms of intoxication.

22. **Sodium Chlorid.**—From experiments carried out on himself, Stookey concludes:

1. Excessive quantities of NaCl apparently exert an inhibitory influence on HCl secretion and thereby may impede gastric digestion. (This is in harmony with Miller's observations.)
2. The ingested NaCl is apparently not directly converted into HCl in the stomach to the extent—if at all—which one might theoretically expect, assuming the theories of Koeppe and Brasch to be tenable.

27 *The Roentgen Treatment of Malignant Disease. Charles L. Leonard.
28 Acute Urethritis. D. A. Sinclair.
29 *A Contribution to the Therapeutics of Children. N. G. Price.

23. **Immunization from Tuberculosis.**—The results obtained by Behring, Pearson and Gilliland in the prevention of bovine tuberculosis are first noticed by Flexner, who calls attention to the early work of Trudeau in this country as a pioneer in this particular therapeutic progress. He says it is a matter of congratulation and national pride that the first steps to the later important studies on tuberculosis just mentioned should have been supplied by American investigators, Theobald Smith and Trudeau.

24. **Tropical Diseases.**—Among the diseases described in this fourth lecture by Kieffer is epidemic gangrenous rectitis, which consists in a rapidly-spreading dysenteric process ending in perforation and gangrene and largely fatal, the causes of which are obscure. Hill diarrhea, an acute morning diarrhea with white stools and marked flatulency, is seen only in the acclimated colonists when they remove from the tropical districts to the hills. Lastly he speaks of sprue, which is a disease of the entire tropical world, and, as a rule, but a terminal condition of many devitalizing and depressing factors. Its cardinal symptoms are: 1, sore mouth; 2, flatulency, and 3, diarrhea. Its course is slow and chronic. It may shade off from chronic dysentery, and it is hard to say sometimes where dysentery ends and sprue begins. The treatment consists in an absolute milk diet, increasing the quantity until the patient will take and assimilate a gallon of milk a day. From this point on the milk diet must be continued for four to six weeks and the soft diet very gradually resumed until in the course of months a mixed diet may be again assimilated.

26. **Pneumonia.**—The great majority of cases of pneumonia in the young and robust will recover under any treatment that is not depressing, and no uniform plan can be formulated. After 50 or 60 years it becomes a more serious condition. The principal indications for treatment in pneumonia are: 1. Pain which, when it interferes with the pulmonary function, is injurious and demands relief. In most cases the external application of leeches will suffice; occasionally a small dose of morphin may be needed, but only in the early stages of the disease. If the temperature remains persistently at a high level, measures must be taken to reduce it. Henry finds sponging with tepid or cold water, or ice bags useful. Of drugs he has most confidence in quinin injected beneath the skin. Delirium and sleep-

lessness call for active interference. Alcoholic stimulants are imperatively demanded, he says, especially in cases where the patient has been accustomed to them. Of drugs, the bromids, especially the ammonium salt, paraldehyd, etc., are those which give the greatest benefit in insomnia. In cough and expectoration he finds good effects from oxysulphuret of antimony. It is of decided service in the early stages of pneumonia in doses of 1/32 of a grain every two hours dissolved in water or in equal parts of syrup of acacia and orange flower water. It is not irritating to the gastrointestinal tract nor does it seem to be depressing. The drugs he notices are digitalis, which is too much used as a routine practice, and is injurious when the arterial tension is increased, ammonia, which may be employed in connection with digitalis, and strychnin, which is of decided value. Oxygen inhalations may be palliative, but he has been rather disappointed in their use. Nitroglycerin is successful in relieving venous congestion, but the most valuable of all recent contributions is the use of quinin subcutaneously as suggested by Petzold. The dose for adults is 0.5 of quinin hydrochlorate in 17 parts of water. Henry has used it and found it decidedly valuable, generally prescribing the more soluble hydrochlorosulphate. Lastly, he speaks of hypodermoclysis, which he has found useful in several desperate cases of lobar pneumonia. Venesection may be occasionally useful. He has seen but few cases, however, in which it was indicated.

27. **X-Rays.**—Leonard finds that the alterative and destructive action produces retrograde changes. In large subcutaneous growths of low vitality, such a rapid destruction may take place as to flood the system with toxins and cause a fatal autointoxication and septicemia. The bad effects noted by some observers, such as a stimulation of the growth of the tumor, were probably due to this cause or to a real stimulation by too small a dosage. When the proper dosage shall be determined for the various manifestations this agent will probably prove one of the most potent ones. Until then operative treatment will have to precede it and the *x*-ray treatment deal with the residua that has escaped the knife. As a preliminary method it has no place at present, except where operation is contraindicated or more cosmetic results may be desired, and life is not threatened by delay, or when the disease is already inoperable. It must be employed with as great care as any other agent possessing such marked alterative properties.

29. **Heroin.**—Price has found heroin of special value in the diseases of children such as whooping cough, bronchitis, false croup, epilepsy, urinary incontinence, diarrhea, chorea and asthma. He gives cases to illustrate the antispasmodic, sedative and analgesic effects of the drug in children.

30 Rudolf Virchow—An Appreciation. Charles A. L. Reed.
31 *Residual Urine. Henry E. Hale.
32 *The Etiological Significance of Heberden's Nodes. Edward M. Merrins.
33 *On the Local Effects of Aurantia and Its Treatment. W. Moser.
34 The Influence of the Mind Upon the Body. John B. Huber.

31. **Residual Urine.**—Hale suggests that in many cases the cause of residual urine may be enlargement of the middle lobe of the prostate behind the internal orifice of the urethra, and that the patient can be relieved if told to void urine twice daily in the knee-elbow posture. He has a patient nearly 82 years old who for the last thirteen months has found this practice of great service. After the bladder wall has lost its tonicity, this will be of no avail; it is only in the earlier phases that it is valuable.

32. **Heberden's Nodes.**—Merrins concludes that Heberden's nodes are simply evidences of structural degeneration depending on etiologic factors of wear and tear, rheumatic disease, mechanical, chemical, or toxic irritants in the system, and lowered vitality and disturbed innervation. Their common occurrence in women is due, he suggests, to the larger use of the smaller joints of the fingers in their daily work. These are likely to occur in any condition where these factors mentioned are present and are most prevalent in those chronic diseases where morbid bony changes form the principal feature of the disease, as in gout, and the osteoarthritic variety of rheumatoid disease. Their presence may help in the diagnosis, but they should never be regarded as conclusive evidence of any particular disease, nor are they of sufficient pathologic importance to constitute a separate form of rheumatoid disease when they appear as an isolated phenomenon.

33. **Aurantia.**—Aurantia is a coal tar dye used in the arts and in color photography. The unpleasant results occurring from handling it were formation of vesicles, swelling, intolerable itching, etc., very similar to those from ivy poisoning. He recommends the formula which he used in the latter condition, consisting of creolin, 2 drams; the fluid extract of grindeliæ, ½ ounce, water 5 ounces, applied on saturated cloths.

Cincinnati Lancet-Clinic.

35 *Goiter and Its Treatment. P. M. Sater.
36 Tuberculosis-Sanitation. H. H. Spiers.
37 Surgery of the Prostate, Pancreas, Diaphragm and Spleen. (Continued.) B. Merrill Ricketts.

35. **Goiter and Its Treatment.**—The treatment recommended by Sater consists in first washing out the alimentary tract with calomel, with sodium bicarbonate and podophyllin; follow this with a hot salt water bath twice a week (in some cases only as a moral treatment); then begin by treatment with potassium iodid in small doses, usually about 2½ gr. freely diluted, after meals only. The next prescription contains 5 grains to each dose, while the third contains 7½, and for the fourth prescription, unless contraindicated, about 10 grains to each dose, continuing the latter for a few weeks until diminution in size of the gland appears; then is added one ounce of buchu, juniper and acetate of potassium, which later is increased to two ounces, thus making one-half the amount of the medicine buchu, juniper and acetate of potassium. This is continued until the cure is effected, which may be in from 30 to 90 days. An eruption like that of measles may occur, but will only necessitate reduction in the size of the dose. He insists on the importance of diuretics in the treatment, and says that he has had very satisfactory results from this method. This, of course, does not apply to the cystic form, of which he has had but one case.

Virginia Medical Semi-Monthly, Richmond.

January 23.

38 *Provision for the Criminal Insane. William F. Drewry.
39 Aid of the Microscope in Diagnosis of Diseases of the Skin. C. S. Venable.
40 *Remarks upon Some Indications for Wearing Glasses. John P. Davidson.
41 Some Practical Points About Diseases of the Eye and Ear. Albert A. Cannaday.
42 Some Cases of Recurrent Intestinal Obstruction Deceptive in Symptomatology and Unique in Causative Agency. William L. Robinson.

38. **The Criminal Insane.**—Drewry's article is a plea for special provisions for the criminal insane in Virginia either by a particular asylum, which is not advisable at the present time with the small number, or by the establishment in the prisons of a special department for their care.

40. **Use of Glasses.**—Davidson advises the use of glasses and thinks that the correction of nervous symptoms is an even more important indication for their use than the improvement of vision. The glass which accomplishes this is by no means the one that gives the best distant vision when first worn.

43 A Case of Colloid Disease of the Blood Vessels of the Spinal Cord. F. X. Dercum.
44 *Arteriosclerosis of the Spinal Cord. William Hirsch.
45 *The Microscopic Findings in Four Gasserian Ganglia Removed for Trigeminal Neuralgia. Sidney I. Schwab.

44. **Arteriosclerosis of the Spinal Cord.**—This condition is, Hirsch remarks, rarely diagnosed. He thinks we must attribute it to a special predisposition. It is not by any means confined to the aged; arteriosclerosis has been observed in infants only a few months old. He has seen sclerosis of the peripheral arteries and heart in a number of young men between 20 and 25. A sharply-defined clinical picture can not be given, as might be supposed. The characteristic feature, however, is the fact that the cells of the anterior half of the cord are much more apt to become affected than those of the posterior part, and he explains this by the peculiarities of the blood supply.

Motor and trophic symptoms are much more frequent than the sensory ones. The diagnosis may be difficult; the clinical symptoms may closely resemble those of tabes or paresis. The Argyl-Robertson pupil, however, is lacking. He reports cases which had a close resemblance to both tabes and paresis. He thinks that the cases which he reports indicate that there is a special form of arteriosclerosis located in the spinal cord.

45. **Neuralgia.**—Schwab reports a microscopic examination of four gasserian ganglia removed for neuralgic troubles, and gives his conclusions as follows:

1. In six ganglia removed for trigeminal neuralgia, anatomic changes were found of sufficient importance to bring them in relation with the symptoms of this disease. 2. These changes in the cells do not point to them as the primary cause of neuralgia, but they may be taken to represent the effects of abnormal cell activity, the origin of which we are not able to point out. 3. The gasserian ganglion is the anatomical seat of the chief symptom of trigeminal neuralgia, that is, the attacks of neuralgic pain.

63½ Apparatus for Intratympanic Hot-Air Treatment of Certain Forms of Catarrh of Middle-Ear. Adolph Bronner.

48. **Otitis Media Insidiosa.**—Hartz's article may be summarized as follows: Sclerosis is fundamentally a hyperplasia of the bony capsule of the labyrinth, or really a transformation of cartilage into bone, accompanied by hyperostosis. It is initiated by constitutional diathesis, such as rheumatism, gout, syphilis and scrofula, and is favored by local disease in the pharynx and throat, etc. Its locality is usually in the labyrinth capsule near the stapes articulation with the oval window, including fixation of the ossicles. It may involve also the semi-circular canals and cochlea, producing symptoms of nervous deafness. The functional test, the subjective symptoms and family history allow an early diagnosis. The symptoms are hyperemia of promontory, heredity, Schwabach test showing prolonged bone conduction, Rinne negative in a varying degree, defective perception of one-half to one and one-half octaves of the low tones. Probably 10 per cent. of the middle-ear diseases are true sclerosis, designated as capsulitis labyrinthi, oto-sclerosis, spongification, dry middle-ear catarrh, and otitis media insidiosa. Hygienic and medicinal treatment are effective in the early stages of the disease. The more advanced stages may be improved by judicious treatment, with amelioration of the tinnitus.

49. **Mastoid Operation.**—Jackson advocates radical operation when, without mastoid symptoms, suppuration has continued three of four months after ossiculectomy followed by wick treatment. The only objection is that the hearing is occasionally affected and the discharge is not invariably cured. Failures are chiefly due to neglect to remove all diseased tissue, neglect of the after-treatment and the combination of a closed retro-auricular wound with a small meatal aperture. An adequate meatal aperture can only be secured in the Stacke, Körner, Pansa and similar operations by extending the flap incisions far out into the concha. Either method will leave a gaping meatus amounting to deformity. Any attempt to get along without this will result in troublesome after-treatment and occasional failure.

55. **Mucin and Malignancy.**—Stuart-Low holds that mucin has a bactericidal property which has been overlooked and that its free secretion is a protection against malignant disease. He finds that hypomyxia is a common antecedent of malignancy. It is hereditary. He reports cases of cancer treated with mucin with more of less benefit.

68 A Case of Localized Tuberculosis at the Head of the Optic Nerve; Microscopic Examination. Arnold Knapp.
69 *A Method for the Prevention of Symblepharon After Burns of the Conjunctiva. E. F. Snydacker.

65. **Sclerosis of the Choroid.**—Levinsohn reports a case with changes of retinitis pigmentosa, pallor of disc, narrowing of the vessels and the irregular deposition of pigment in the retina, indicating atrophy of the retina, together with marked atrophy of the choroid extending nearly to the periphery and otherwise leaving only the macular region free. Near the disc the choroidal atrophy appears in the form of large white areas beneath the retinal vessels. Further, it is recognized by the lighter tint of the fundus and the clearness with which the choroidal vessels are seen, but the changes in the vessels are the characteristic symptoms and the primary lesion.

69. **Symblepharon.**—Snydacker describes the method of treatment employed by him for symblepharon, which consisted in sandwiching the lower lid between two lead splints cut to fit and sutured together through the lid and having them drawn down by a bandage passing under the chin. This completely separates the wounded areas and keeps them stretched apart under constant tension while healing is taking place.

70 *Measuring, Fitting and Putting on the Corset for Movable Kidney or Glenard's Disease. A. Ernest Gallant.
71 Nose and Throat Work for the General Practitioner. George L. Richards.
72 *What Is the Significance of Cervical Lacerations? Chauncey D. Palmer.
73 The Surgical Assistant—Operations on the Head. Walter M. Brickner.
74 *Bunions and Their Treatment. Robert T. Morris.
75 The Technics of Amputations. Robert H. Cowan.

70. **Glenard's Disease.**—From a careful consideration of others' work and his now wide experience, Gallant concludes that the symptom-complex, called movable kidney, Glenard's disease, etc., can not be accounted for on the ground of simple kidney mobility or prolapse. The nephroptosis is nearly always associated with ptosis of other abdominal and pelvic viscera, subnormal nutrition and nervous instability, and the treatment to be successful must be directed toward the replacement and support of the prolapsed organ, the correction of functional derangement, and the improvement of general nutrition. Nephropexy alone will fail and is indicated only when operating on a true "surgical kidney." The remedy he suggests is a corset, measured, fitted and put on while the woman is lying in the dorsal position with pelvis raised, and worn continuously, when not lying down, to elevate and support the viscera and immobilize the wandering kidney. It affords maximum pressure over the suprapubic area, minimum compression above the waist-line, and ample space for heart, lungs and intestines; gives a refreshing sense of comfort as soon as put on; Dietl's crises cease, and as time goes by gastrointestinal action improves; anemia is dissipated and a well-marked increase in body weight ensues. Such a corset has been found of great use to women with pendulous abdomens or adiposis, to replace the abdominal binder after childbed and celiotomy, and for

young girls when first they adopt skirts suspended from the waist. The wearing of such a corset is prophylactic against the production of Glenard's disease.

72. **Cervical Lacerations.**—The importance of cervical lacerations is insisted on by Palmer, who remarks as to their tendency to favor malignant growths and suggests the importance of their early recognition and correction.

74. **Bunions.**—A very simple operation will relieve most cases of bunions according to Morris:

A longitudinal incision, not more than half or three-quarters of an inch in length, along the line of the inner surface of the extensor tendons, exposes the site of the hyperostosis, and a sharp chisel separates the button of the bone readily from the head of the metatarsal bone. The open bursa can then be trimmed out with a pair of scissors without difficulty, and when the wound is sutured and the skin pressed against the surface of bone from which the button was removed, it becomes quickly adherent and the bunion is at an end. This treatment will suffice to give comfort in most cases and no further operative work is necessary, but if the patient wishes to have the phalanges of the great toe placed in normal line with the metatarsal bone it is necessary to divide the external ligament of the metatarso-phalangeal articulation. This can be done subcutaneously, but in doing so we can not avoid cutting a pretty large branch of the dorsalis pedis artery, as a rule.

Hemorrhage from this cut artery we can usually disregard if a small, round, gauze pad is strapped firmly down on the dorsum of the foot at this point beneath a light splint. We must inform the patient, however, that sometimes it becomes necessary to enlarge the incision and ligate the artery. I have not been obliged to do this as yet, but have had to exercise a certain amount of skill in making proper application of pressure.

After the simple operation of removing the button of bone, and the thick bursa, very little further treatment is required, and the patient may be allowed to walk in from ten to twelve days.

Where it has been thought desirable to correct the hallux valgus by division of the external lateral ligament, we must apply a splint to be worn inside the shoe to hold the phalanges in place for several months. A very good one is made by hammering a piece of sheet copper into the shape of the sole of the foot, and turning up a flange which corresponds to the external surface of the great toe. A special stocking is then made with a separate compartment for the great toe, so that the flange from the splint can be interposed between the great toe and the next one.

81 *Facts, Fancies and Fallacies in the Treatment of Consumption. M. J. Brooks.

76.—This article has appeared elsewhere. See THE JOURNAL, Feb. 21, p. 539, abstract 19.

77. **Urethral Stricture.**—Gouley's article reviews the whole subject of stricture and points out the treatment suitable for each variety.

78. **External Perineal Urethrotomy.**—Syms describes the operation and considers it a safe one and the operation of choice in urethral rupture, in intractable stricture, impassable stricture with urinary retention or false passages or urinary extravasation, and in those with an abscess or fistula. He thinks it might be the treatment of choice in cases of deep-seated strictures, even though they might be amenable to gradual dilatation, since the latter method never results in permanent cure, but must be repeated or continued at longer or shorter intervals. In emergency cases of sudden complete retention due to prostatic obstruction, where unwise instrumentation has been attempted, resulting in laceration of the urethra, etc., perineal urethrotomy is the safest and best procedure.

79. **Internal Urethrotomy.**—The objections to urethrotomy are reviewed by Hotchkiss, who holds that a well-planned and well-executed urethrotomy is often followed by permanent results as regards reconstruction, and that many cases that are ordinarily treated by external urethrotomy may be well and safely treated by the method of dilating internal urethrotomy combined with perineal cystotomy for drainage.

81. **Tuberculosis.**—The favorable conditions for the treatment of consumption are not to be found, according to Brooks, in climate, altitude, etc., or in the wards of general hospitals. What is wanted is a space of open country with a number of properly-equipped and supervised sanatoria in the neighborhood of our larger cities, and seaside institutions for tuberculous children.

83 *Prognosis in Neurasthenia. J. M. Bradley.
84 *The Removal of the Malleus and Incus Under Local Anesthesia in Chronic Suppurative Troubles of the Middle Ear. Selden Spencer.

82. **Renal Diagnosis in Surgery.**—While blood cryoscopy has some inconveniences, urinocryoscopy, in connection with the separation of the urines, Bryson says, is of distinct value and especially in connection with hematocryoscopy. The phloridzin test is a very delicate and valuable one for the investigation of the functional capacity of the kidney. It is not difficult and should precede operation on the kidney whenever possible. Until further observations, the freezing and phloridzin tests should be made separately. The polyuria often caused by phloridzin may interfere with the freezing-point of urine from the healthy kidney. These tests should be regarded as aids only to diagnosis and as in no way taking the place of well-established methods.

83. **Prognosis in Neurasthenia.**—Bradley finds that neurasthenias due to external toxins are usually rapidly relieved by removal of the cause. Cases from overwork recover by rest provided the damage done is not too great. Those cases following childbirth or lactation without sepsis are favorable; with sepsis not so much so. Cases following infectious diseases and septic states are not so satisfactory; recovery is slower and likely to be interrupted and relapses are more likely. Natural sexual excesses do not ordinarily cause cases of neurasthenia of bad prognosis, unless they occur in persons approaching the age limit who have all their life been excessive. Neurasthenia from unnatural practices depends entirely on the mental attitude of the patient. If they can control themselves and change their habits, prognosis is good, otherwise bad. Neurasthenia from worry is rebellious to treatment, and is usually of long standing before coming to the physician. Improvement is slow, interrupted and subject to relapses. Neurasthenia from disordered metabolism has a wide range of possibilities. The prognosis regarding permanent cure is not so good. He calls attention to the effect of coffee in depressing the reflexes and finds that in cases of neurasthenia, other conditions being equal, if the reflexes are decreased, recovery is more rapid and permanent than when they are increased. This may possibly be due to coffee as a cause and its stoppage helping the case.

84. **Ossiculectomy.**—Spencer performs ossiculectomy under local anesthesia, first using adrenalin to render the parts bloodless and then applying a local anesthetic on cotton.

87 Kidney Complications in Estivo-autumnal Fever. Ira B. Bartle.
88 A Case of Smallpox, with Sequelæ. W. T. Braun.

85. **Dyspepsia in Consumptives.**—The apparently pretubercular dyspepsia is described by Paquin. He does not think that it absolutely precedes tuberculosis, and insists on the importance of strength rather than gain in weight as a favorable symptom in the prognosis. He thinks we should look on persistent indigestion with the greatest solicitude, and watch the victims closely, so as to place them, if possible, in the condition to defeat the greatest plague of man—consumption.

86. **Dysentery.**—Goltman has treated dysentery, as he thinks, of the amebic variety, by local treatment and divulsion of the rectum. His conclusions are:

1. The treatment of dysentery, acute or chronic, by topical application is most rational. 2. Topical applications are useless unless large volumes of fluid are used to distend the bowel. 3. Topical applications, as usually made, are very painful in all cases, particularly in those that are acute. 4. Topical applications, to be thorough and far-reaching, are unbearable to the patient, on account of the extreme pain they cause. 5. Anal divulsion is a prime factor in facilitating the work of flushing the colon. Resistance to the escape of fluid is removed, and it markedly relieves the tenesmus. 6. Anal divulsion, cauterization of ulcers through the proctoscope, passage of a tube high up into the sigmoid through this instrument and thorough distension and flushing of the gut, are absolutely impossible without the aid of anesthesia. 7. Anesthesia rather relieved than produced shock in my cases. These patients

seem to take as kindly to chloroform as women in childbirth. 8. In my judgment, one is more likely to overdistend and perforate the gut without anesthesia than with it.

1. **Rheumatism.**—Beatson and Walker have studied the bacteriology of rheumatism and come to the conclusion that a particular micro-organism is constantly associated with acute rheumatic lesions; that this organism can be cultivated on artificial media, and that on inoculation into animals it gives rise to the characteristic lesions of the disease and can again be isolated from them. Culturally this organism resembles the streptococcus, but it appears different from the streptococcus in its reaction with the Marmorek test. The bacterial specificity of rheumatism, they conclude, is, therefore, satisfactorily established. Its toxic specificity is yet to be investigated and is at present under examination.

2. **Old Age.**—Keyworth points out the disadvantages of old age in disease. He holds that attention to diet is necessary; old people who are healthy and live well are generally spare

and eat but little. A man must reduce his intake after fifty years. Cold weather is especially severe on elderly people, and he calls attention to the danger of high tension pulse in renal disease and the necessity in such cases to keep the bowels free, avoid meat and malt liquors. The reactions and sympathies between different organs which aid in the diagnosis are much less marked in advanced age than before, and pneumonia and empyema may be latent as regards symptoms. Any general ill-defined illness in an old person should suggest pneumonia. Cancer rarely appears first in old age, and when present is often slow in its progress and may disappear. The power of repair of tissues and recovery from injuries is often good. Diuretics as well as laxatives are valuable, as the skin is less active. Quinin is valuable and he recommends wine and exercise, especially walking.

3. **Smallpox and Chicken-pox.**—The following are the tentative conclusions reached by Thomson and Brownlee in their research for the past five years on the parasites of varicella and smallpox: There are present in the blood of persons with hemorrhagic smallpox small spherical bodies highly refractive, simulating in appearance small fat globules. They do not stain, however, with osmic acid, nor with the usual basic or acid stains. In hemorrhagic cases they were found in considerable numbers from the third or fourth day until death. Similar bodies in lesser numbers were found in cases of confluent smallpox from the third or fourth day until the end of the first week or later and abundantly in the prodromal stages of both smallpox and chicken-pox. These were unlike any ordinary histologic or pathologic constituents of the blood and much larger than hemoconia (size 1/5 microns). 2. In skin sections containing hemorrhages similar bodies are found among the extravasated blood corpuscles, but these stain very faintly with both basic and acid stains. 3. In the lymph spaces and in some of the smaller blood vessels of the skin there are often groups of small spherical bodies, considerably larger than staphylococci and staining with considerable difficulty. Their staining capacity, however, varies considerably. 4. In the lymph spaces of the skin, especially those immediately adjacent to the basement membrane of the epithelium, there are found considerable numbers of small spherical bodies, more closely grouped in certain situations. They are larger than streptococci and stain with comparative ease with most basic dyes. These commonly assume a peculiar purplish tint, different from the green of the cocci and nuclei. 5. In skin sections, if taken where the eruption is moderately advanced, bodies such as are described are present and can be recognized in large numbers in the epithelial layers. They are difficult to recognize among the disintegrating nuclei. 6. In smears from the vesicles similar bodies are found and are often present in small numbers in the blood from patients suffering from hemorrhagic smallpox. 7. In smears taken from the pocks in later stages of eruption, within certain of the cells small clear bodies may be found staining very faintly with the ordinary reagents. In smears of gradually increasing age, these bodies are seen to increase in size until they occupy the larger part of the cell, and at a still later decade they are found apparently in a free state. They stain very faintly and show no appearance of a nucleus. 8. The absence of pyogenic micro-organisms, both from smears and skin sections, is very striking in the hemorrhagic cases and during the early stage of rash. 9. Towards the end of the vesicular and in the pustular stage pyogenic organisms are frequently found in sections, smears and cultures. 10. Appearances similar to those described in smears, vesicles and pustules of the skin in variola occur also in varicella. In severe hemorrhagic and confluent cases, pyogenic organisms are very commonly found in the blood, but these have been regarded as due to accidental contamination and in hemorrhagic cases probably from the lungs, in confluent cases by absorption from the skin and, possibly, the lungs also.

4. **Urinary Test for Lead.**—Jacob and Trotman describe an electrolytic test which they consider one of the most delicate. It consists in evaporating about 250 c.c. of urine in a porcelain dish with a few c.c. of lead-free sulphuric acid placed over the flame and about 5 grams of potassium persulphate are added, little by little, with occasional stirring, as the temperature of the liquid is gradually raised. In about half an hour the contents of the dish will have become almost colorless, owing to the oxidation of the organic matter. When the liquid is concentrated to about 50 c.c. it is introduced into a platinum dish and an electric current passed through it for about eight hours. Before beginning, the poles are tested by introducing the terminals into a salt solution containing a few drops of phenolphthalein. After allowing the current to run for a sufficient time, the liquid is poured away and the dish well washed with distilled water. Hydrochloric or nitric acid is then added and, after digesting in a water bath or heating over a Bunsen flame, a stream of sulphuretted hydrogen is passed through the liquid. The quantity of lead present can be accurately determined by matching the color with the standard solution of lead nitrite. Great care should be used in obtaining lead-free sulphuric acid, and all material should be tested. In this way they have detected the most minute quantities of lead when other tests have failed.

9. **Human and Bovine Tuberculosis.**—In this preliminary note, Raw holds that there is some evidence to assume that tabes mesenterica is not true tuberculosis nor caused by the same organism as the pulmonary variety. He also concludes:

1. That there are two distinct varieties of tuberculosis affecting the human body, one produced by human tubercle, and the other produced by bovine tubercle. 2. That human and bovine tuberculosis are separate and distinct. 3. That bovine tuberculosis entering the alimentary canal in milk may set up tabes mesenterica, more especially in children. 4. That bovine tuberculosis is probably the cause of enlarged lymph glands, tuberculous joints, and lupus. 5. That true human tuberculosis or phthisis pulmonalis is always conveyed from one person to another by infection, and generally from advanced cases of phthisis. 6. That every effort should be made to stamp out tuberculosis in cattle, and that milk should be boiled before use by children.

12. **Astereognosis.**—After reporting a case in a tabetic patient, Rennie discusses the condition and concludes that when it occurs in this condition it is a manifestation of dissociation of these special sensory perceptions which in a normal person are all co-ordinated in the higher sensory center in the brain. That it does not occur in every case of tabes is proof of the random action of the toxin, which seems, in some cases, to affect the different peripheral sensory structures or afferent nerve fibers.

13. **Birth Paralysis.**—This condition in the upper extremities is described by Kennedy, who advocates operation and suturing of the brachial plexus. He has operated on three cases, one of which has made a good recovery. In the other two, sufficient time has not elapsed to draw a conclusion.

16. **Vaccination During Menstruation.**—Dawson reports a case in a healthy girl where vaccination seemed to cause amenorrhea, with serious disturbance, lasting for several months. At one time the symptoms suggested gastric ulcer, vomiting of blood ushering in the return of her normal menstrual periods.

19. **Bilberry (Vaccinium Myrtillus).**—Bernstein finds this, the European huckleberry, a valuable intestinal antiseptic. He tried it *in vitro* and clinically in enteric fever and dysentery with excellent results. He started fourteen years ago by prescribing it simply for its astringent qualities, giving the jam made from the berries in fermentative diarrheas with flatulence and cases of cholera nostras. In 1897 he tried it for the first time in a case of typhoid in a child. It seemed to him that the disease took a milder course and convalescence was earlier. The second case acted similarly, and likewise two cases in adults.

21. **Abdominal Emergencies.**—Morison says the first duty of the practitioner in attending an abdominal emergency case is to determine whether it is one of the extreme cases or not, and when this is settled one-third gr. of morphin should be injected hypodermically and then operation pushed without a moment of unnecessary delay. In case of general peritonitis, when the abdomen has become distended, operation is too late, but if it is decided against, the first thing is to stop the administration of all food and drink by the mouth, wash out the stomach with an abundance of hot water if vomiting is troublesome and keep the patient perfectly quiet with small and repeated doses of morphin hypodermically. A linseed meal poultice large enough to cover the whole abdomen should be applied for an hour and repeated every eight hours, abundance of heated cotton-wool being substituted in the interval between the poultices. In the less serious cases, we should make a differential diagnosis as rapidly as possible. The first thing is to examine the hernial sites and to learn the history of the case. It is important to know whether the colon lies behind or in front of the tumor and to learn if previous attacks have been followed by jaundice or hematuria. In the female the possibility of twisted pedicle or ovarian tumor is to be suspected, and missing the menstrual period and other signs may indicate an ectopic pregnancy. He thinks that every acute case of appendicitis should be operated on without delay if, after a single dose of morphia and at the end of eight hours, every symptom and sign of danger have not disappeared. The risks of removing the acutely inflamed appendix, the author says, have been exaggerated. In concluding, he mentions pneumonia commencing with abdominal symptoms and suggesting abdominal disease. It is usually in patients past middle life in which this mistake has been made.

22. **Pernicious Anemia.**—This installment of Hunter's article is largely a comparison of Biermer's pernicious anemia and the disease described by Addison. Biermer's anemia is a complexus of conditions which may be produced by many causes. Idiopathic anemia is, as Addison thought, a disorder of definite infective nature, in which both the clinical observations and necropsy reveal well-defined infective and hemolytic lesions invariably associated with the disease and in which a very definite number of points can be got out of the history, throwing light both on the mode of origin of the disease and the sources of infection.

23. **Uric Acid.**—Woods-Hutchinson offers the following proposition, which seems to him, in the light of our present knowledge, the most rationally tenable view of gout and lithemia:

1. There is no connection whatever between the production of urea and of uric acid, hence interdiction and marked limitation of animal or of nitrogenous foods, as such, in gout is irrational. 2. The uric acid produced in health comes exclusively from two sources, the larger moiety, or exogenous uric acid of Chittenden, from the nucleins and purin bases of the food, the smaller, or endogenous moiety, from the destructive metabolism of the nucleins of the body tissues. 3. It is the endogenous moiety alone which is increased in gout and lithemia. 4. Gout and lithemia are mere symptom names for a miscellaneous group of chronic toxemic processes of widely varied origin, characterized by the production of uric acid and the urates. 5. By "gouty diathesis" we mean the possession of a sufficient degree of resisting power on the part of the protective cells of the body to oppose the entrance of any poison, whatever its character or source, with consequent destructive metabolism and production of uric acid, but not adequate to neutralize or successfully to prevent its absorption. 6. The uric acid of gout, like the phosphoric acid which invariably accompanies it, is merely a result and measure of the destructive metabolism of the nucleins of the body cells, chiefly probably of the leucocytes, in response to the invasion of poisons or toxins, either organic or inorganic (lead, phosphorus, alcohol, acetone). 7. Hence the use of lithia or other "solvent" agents is irrational, and any benefits resulting are to be explained on other grounds. 8. As most of the toxins setting up this destructive metabolism and consequent uric acid production are of intestinal origin or entry, diet in gout should be regulated solely with regard to the diminution of intestinal fermentation and putrefaction. 9. As animal foods, from their much more appetizing and attractive flavors, are more apt to be indulged in in excess of the oxidative powers of the body, their limitation may be found to be more frequently necessary than that of vegetable foods, but sugars and starches are also very often at fault. 10. As uric acid and the alloxur group are not toxic, or, at best, feebly so, and are not the cause of gout, the prohibition of even foods rich in nucleins and purin bases, such as red meats, roe and sweetbreads, has no rational basis and is clinically of doubtful utility except by diminishing the attractiveness of the dietary. 11. The rôle of the liver in gout is a negative one, being inability to perform its chief normal function as a "poison filter" and to absorb or to transform into harmless excretory substances the excess of toxins brought to it by the portal vein. 12. The drugs found of value in gout owe their efficacy chiefly to their power of checking intestinal putrefaction or of preventing the absorption or promoting the elimination of its products.

24. **Gastric and Duodenal Ulcers.**—Moynihan discusses the treatment of chronic and acute gastric and duodenal ulcer. He finds there is a possibility of recovery from the subacute and, perhaps, from acute perforation of the stomach without operation. He does not excise the ulcer in operating, but uses continuous sutures of catgut taken wide of the ulcer, folds the stomach walls over and buries the rent. A second continuous suture of Pagenstecher thread is placed outside the first. He generally flushes the abdomen if much soiled, and if only a little soiled he wipes it clean with large swabs dipped in saline solution and used at once without being squeezed. Drainage is rarely necessary. He discusses the characteristic symptoms and the character of hematemesis. He says the treatment of hemorrhage will depend on the nature of the ulcer. If from an acute ulcer, medical treatment alone will suffice, and surgery is rarely required. If any operation is to be done, gastroenterostomy is probably the most effective. In chronic ulcer, operation should be advised as early as possible. If readily exposed and not adherent to the pancreas or other organ, the ulcer, if solitary, should be excised, but a simple gastroenterostomy is probably sufficient to secure the arrest of the hemorrhage and the rapid healing of the ulcer. In performing gastroenterostomy he has lately used the simple suture and performed the posterior operation after the method of Von Hacker, the steps of which he describes. He thinks an error in the proper adjusting of the anastomosing loop is an undoubted cause of regurgitant vomiting, and in such a case he should in the future prefer Roux's operation, "the gastroenterostomy in Y," to any other. In connection with the operation of gastroenterostomy the following points are worthy of attention: Sterilization of the mouth, stomach and jejunum. Washing out mouth and stomach with calomel 48 hours before. He would use india-rubber gloves; no antiseptic, and take scrupulous care to avoid any possible infection from the mucosa. Scissors and clips which touch the mucous membrane are at once laid aside and not used during the subsequent stages of the operation.

28. **Aseptic and Antiseptic Surgery.**—Cheyne advocates the moderate use of antisepsis in surgery, and gives in parallel columns the disadvantages and advantages of the two as he estimates them. The differences are slight, but he believes important. He thinks in giving up catgut the surgeons have lost an important aid in wound treatment, and in the giving up of buried sutures for uniting divided muscles, etc., have taken a retrograde step. There is no special difficulty in asepticizing catgut and he can not conceive what should make silk more difficult of sterilization than swabs, etc. It is not the imperfect sterilization of these which make trouble—it is that they are present in a wound to which bacteria have been admitted by the employment of imperfect bacteriologic methods. He sees no logical reason whatever for giving up the use of antiseptic substances in the use of dressing. They can do no harm and may be a decided defense against infection.

29. **Fibroids of the Uterus.**—Doran's article is too detailed and lengthy to be fully abstracted here. He describes the anatomy of the parts and the specially pathologic conditions observed in broad ligaments, ovarian ligaments, round ligaments and undeveloped uterine cornua. He does not favor oöphorectomy for fibroids, though it can be advantageously done under exceptional conditions.

30. **Electric Shocks.**—Noticing an article by F. B. Aspinall, which appeared in *The Lancet* of March 8, 1902, and abstracted in THE JOURNAL of March 29, §12, p. 849, Jellinek reviews cer-

tain points and questions suggested. He agrees with Aspinall as to the importance of individual susceptibility, and holds that in certain diseases, such as Graves' disease, a lowered skin resistance predisposes to the accidents of electric shock. As regards the different physiologic conditions of the subject, he has made experiments on rabbits and finds that narcosis makes them more resistant. Therefore, the statement of Aspinall that electric shocks are less dangerous during sleep is probably correct. The path which the current takes through the body is important, as Aspinall says, and the left side is more sensitive than the right, but he attributes this not to the effect on the valves of the heart, but rather to the effect on the ganglia of that organ. As regards the effect of burns he disagrees, holding that they are not a protection. The time during which the person is exposed to the current is important. The alternating and direct current shock seem both likely to be fatal or dangerous when of a high voltage. With a low voltage or tension the alternating current is more disagreeable. Instead of there being a difference between the two, in one the direct current paralyzing and the alternating producing spasm, Jellinek finds these currents alike seem to produce severe spasm during their action. The question asked by Aspinall, why medical men can not give us a more certain method of ascertaining whether a man is dead or not is answered by the author that in his experiments on animals he has observed several hours after apparent death signs of life were present, and for this reason he believes that attempts at restoration after shock should be continued for hours, or until some certain signs of death appear. The suggestion made by Aspinall that the body should be held head downward to flush the brain, he considers a very dangerous one, as the capillaries of the central nervous system are torn and, in such a condition, would only run a greater risk of cerebral hemorrhage. It would be better, he thinks, to perform venesection, and artificial respiration should be continued for hours; massage of the abdomen and of the region of the heart, placing the patient in a hot bath, subcutaneous injections of ether, camphor, strychnin should also be carried out. He believes many cases pronounced dead may be revived by taking the necessary time and trouble.

31. **Blood Examination.**—Bryant reports cases illustrating the value of blood examinations which, while not infallible, are certainly of great value.

32. **Intussusception.**—The conclusions summarizes by Rigby from his series of cases are:

1. That in these cases immediate laparotomy should be insisted on without delay; 2, that no valuable time should be lost in attempting inflation of air or injection of fluids per rectum; 3, that the keynote of operative success is rapidity; 4, that in favorable conditions, as in hospitals and with skilled assistants, the mortality of reducible intussusceptions should be diminished to a very small percentage; and 5, that the chief points in the after treatment are (*a*) early feeding and (*b*) the use of opium when necessary.

34. **Pernicious Anemia.**—In this second installment of his article, Hunter gives the etiology of his 25 cases and other facts which seem to him to point out the differences of Addison's anemia from the progressive pernicious anemia of Biermer. He thinks a new nomenclature is advisable, and would suggest for this disease the name "infective hemolytic anemia" or Addison's anemia.

38 Discussion of Value of Arrhenal.
39 *Discussion and Resolution in Regard to Notification of Diseases.

39. **Diseases Requiring Notification.**—The final resolution adopted by the Académie after long discussion was as given in THE JOURNAL of February 7, p. 389, with the exception that epidemic cerebrospinal meningitis was added to the list of diseases requiring compulsory notification. They are as follows: Typhoid fever, exanthematous typhus, variola and varioloid, scarlet fever, measles, diphtheria, miliary fever, cholera and choleriform diseases, plague, yellow fever, dysentery, puerperal infections and ophthalmia neonatorum when secrecy in regard to the pregnancy has not been enjoined, and finally, epidemic cerebrospinal meningitis. A second list comprises the diseases for which notification is optional, and requires the consent of the family. It includes pulmonary tuberculosis, whooping cough, la grippe, pneumonia and bronchopneumonia, erysipelas, mumps, leprosy, tinea and purulent conjunctivitis and granular ophthalmia. The Académie recommended that special postal cards should be supplied for the purpose to all physicians, health officers and midwives, the diseases to be designated by number.

62 Zur Frage über die Einschlüsse in und zwischen den Krebszellen (cell inclusions). W. N. Klimenko.

48. **Progress in Pathology in 1901.**—Kromayer cites as the most important works in this line in 1901 Bockhardt's study of eczema, the isolation of the microörganism of soft chancre, and Blaschko's study of the nerve distributions in the skin and their relations to cutaneous affection. He also mentions Judalewitsch's discovery that the nevus cells thrown up by the epithelium become transformed into connective tissue cells.

58. **Experimental Research with Dead Tubercle Bacilli.**—Sternberg found that he was able to induce the production in animals of the same tubercular lesions by injection of tubercle bacilli whether they were dead or alive. The only difference was that the extension of the process was proportional to the amount injected of the killed bacilli. This result was not constant, and only followed when a thick culture was injected.

78 (No. 4.) *Prevention of Hernia After Laparotomies. J. Hahn. Die Verhütung des Bauchbruchs nach Laparotomien.

63. Prevention of Hernia After Laparotomies.—Wolff ascribes the tendency to hernia to the tension exerted on the suture by meteorism. He therefore directs special attention to the prevention of meteorism and has found that conditions were very much improved thereby.

65. Radical Operation for Congenital Inguinal Hernia in Children.—Karewski states that six to twelve years have elapsed in a number of cases since he operated on congenital hernia in very young children. His method is particularly applicable to severe cases of scrotal hernia, and its simplicity and facility commend it for general adoption. The incision is carried down only to the serosa and the processus vaginalis peritonei, forming the inner layer of the sac, is detached with the fingers. The parts are isolated to beyond the internal inguinal ring and at this point the peritoneum is tied. This affords a firm support and no further radical intervention is necessary even as late as the fourth year of age. The wound heals rapidly, although frequently soiled by the infant's discharges. He applies an iodoform dressing at first, changed every day, and later airol salve.

68. Improved Technic of Rinsing the Stomach.—Neck finds that it is possible to empty the stomach completely under all circumstances, by elevating the pelvis after the ordinary rinsing is finished. By this means considerable amounts of stomach contents can be evacuated after the organ is supposed to be empty. He has confirmed these clinical findings on the cadaver. The most complete evacuation is secured when the stomach tube is gradually withdrawn after the pelvis is raised. This prevents any accumulation of the contents around the tip of the sound projecting into the fluid.

70. Paraffin Prothesis.—Gersuny is much pleased at the reception accorded his method of subcutaneous prothesis, but he does not consider the substitution of paraffin with a higher melting point as any advantage. He still uses what he first recommended: Ung. paraffini with a melting point at 35 or 40 C., but has been experimenting lately with a still softer combination, mixing one part of the above with four parts of olive oil. The oil is gradually absorbed, leaving the encapsulated particles of paraffin at the same distance apart. The size of the prothesis remains the same, but it is not so solid as when paraffin alone is used. When injecting the paraffin into very porous tissue he commences with a very small amount, not more than 1 c.c., and waits a week until this is completely encapsulated before injecting the remainder of the paraffin into the center of the first deposit. His finest cosmetic results have been obtained in cases of hemiatrophy of the face, in raising Thiersch flaps and imparting the natural color to them by the under layer of paraffin, and also in obliterating the pits left by smallpox.

73. Technic of Lateral Gastroduodenostomy.—Kocher thinks that his method of anastomosis between the stomach and the duodenum is far superior to all other methods of gastroenterostomy, as it entirely avoids the "vicious circle," and can be conveniently done outside of the abdomen. Others have used it, and their results confirm his dictum, but they have considered it necessary to restrict it to cases in which the duodenum was movable. This is not necessary, he states, as it is easy to mobilize the duodenum in all cases unless it is extensively adherent to the liver. The loop of the duodenum hangs free during embryonal life, and is still very movable in children, but later becomes adherent to the posterior wall of the abdomen, whence it is easily detached, as can be established on the cadaver. The thin sheet of the parietal peritoneum is slit perpendicularly to the right of the descending portion of the duodenum. The incision passes in front of the right kidney, to the left of the descending part of the right flexure of the colon passing downward to the transverse colon. The parietal sheet of the peritoneum passes here from the anterior surface of the kidney to the colon and forms the upper sheet of the transverse mesocolon. The finger can be passed along the vertical portion of the duodenum above the peritoneal sheet of the kidney and into the foramen of Winslow, and thus lift up the hepato-duodenal ligament with the hepatic artery, portal vein and common bile duct. The thin sheet of peritoneum should be incised, not torn, parallel to the vertical portion of the duodenum and at least two finger widths from it. The portion of the sheet adherent to the duodenum can then be lifted and two fingers passed behind the latter, thus gently detaching it from the anterior surface of the spine, vena cava and aorta. The lower flexure of the duodenum can also be mobilized in the same way by slitting the peritoneum passing down to the colon. No large vessel is injured by the procedure. The head of the pancreas is raised with the duodenum so that the concave margin offers no resistance to the lifting of the duodenum. The posterior surface of the duodenum is not exposed down to the muscularis. It retains as the remains of its former peritoneal covering a sheet of connective tissue which, in comparison to the rest, has a raw appearance. These maneuvers mobilize the vertical portion of the duodenum to such an extent that it can be readily laid against the anterior surface of the pyloric portion of the stomach, above the greater curvature. The mobilization of the duodenum is restricted by the vessels, especially that of the superior flexure, but sufficient for the anastomosis, can easily be mobilized and the conditions realized by the change of position of the loop are peculiarly favorable for the anastomosis, as the duodenum retains its peritoneal covering intact on its anterior surface, now turned toward the left for union with the stomach. He has performed the operation by this technic in 5 cases, once for carcinomatous and four times for cicatricial stenosis of the pylorus.

74. Transplantation of Tendon for Flat Foot.—Müller detaches the tendon of the tibialis anticus from its attachment and draws it through a hole bored for it in the navicular bone, about the size of a pencil, passing from below upward and a little to the rear. The tendon is drawn through with a thread and is then pulled downward while the foot is pressed into normal shape. The end of the tendon is then drawn around the inner surface of the navicular and fastened to the bone with a wire suture. This holds the foot in its normal arched shape as if by a bridle. He emphasizes the necessity of cutting the Achilles as an indispensable preliminary to this and numerous other interventions on the foot.

76. Technic of Artificial Gall Bladder Fistula into Intestines.—Thomson's article is a plea for the more general use of the Murphy button for these operations.

78. Prevention of Hernia After Laparotomy.—Hahn attributes his success in the avoidance of post-operative hernias in a series of 88 laparotomies, to the use of sterile silk for the sutures, to the complete healing in of the threads and to his method of isolated suturing of the peritoneum and transverse fascia, then suturing the aponeurosis, exclusive of the muscle, as the fibers of the latter are liable to tear, concluding by the suture of the skin with a supplementary buried suture in case of much fat. In preparing his hands he cleanses them mechanically, he states, in hot soapy water for forty minutes and then devotes ten minutes more to the rinsing, drying and soaking in a 1/1000 solution of sublimate. He draws the threads in the skin the seventh to ninth day, and allows the patient to get up the thirteenth. No abdominal bandage is worn.

79. **Vaginal Cesarean Section.**—Bumm describes in detail 13 cases treated by vaginal cesarean section, which establish, he believes, that section of the anterior wall of the cervix alone is ample enough for nearly all cases, even at term, when there is no malignant growth and the uterus is to be retained. The portio is exposed and the sides seized with Collins' forceps. A sagittal incision from 5 to 7 cm. in length is then made in the mucosa of the anterior vaginal vault to the lip of the os. The loose cellular tissue between the bladder and cervix is cut with a few strokes of the scissors and the bladder pushed back to the orific. int. The anterior wall of the cervix is then incised on the sagittal line to this point. The upper edges of the wound are then drawn aside with two Collins', as for vaginal myomotomy. This exposes the lower segment of the uterus, and after the bladder has again been pushed out of the way, the uterus wall is incised. By this means an incision 8 to 12 cm. long can be made under complete control of the eye and without opening into the peritoneum. Even a fetus at term can be readily extracted through it. The bleeding is most profuse when the mucosa of the vagina is incised. He waits for the spontaneous expulsion of the placenta, which usually follows in fifteen minutes. He sutures the uterus with a row of catgut sutures and has never observed any mishaps or complications. In one case the incision measured exactly 7 cm. from the orific. ext. upward, and through it a child weighing 3,250 gm., with a suboccipito-frontal circumference of 34 cm., was extracted without trouble. The lips of the wound, therefore, must stretch, but they have never torn in his experience. The vaginal walls are more resistant than the incised cervix, in primiparæ, and lacerations are liable to occur in the perineum, vulva and side walls of the vagina. In the 13 cases described only one terminated fatally, and in this case the death was undoubtedly due to the severe eclampsia. In 8 the patients were aseptic, and there was no febrile reaction to the operation. Fever was noted four times; in two the patients had been infected by repeated examinations before entering the hospital; in one a pregnancy nephritis with edema prevented the union of the parts, and in one the uterus contained a purulent carcinoma. The wound in the vaginal vault and cervix healed faultlessly, with the exception of three infected cases. This median anterior hysterotomy leaves a harmless, easily healing wound, which does not interfere with further function of the parts. Even in a case of severe streptococcus infection, as the plica anterior of the peritoneum was not opened, there was no peritonitis. He has become convinced by his experience that in eclampsia the patient should be delivered at once after the first attack as the only means of safety, and he has found vaginal cesarean section the best method, if natural delivery be impossible. He thinks it is a less dangerous procedure than rapid dilation with the metal dilators, which are apt to lacerate the cervix. In one of his cases the operation was undertaken on account of the placenta previa, and the results encourage him to believe that this will be found the best method also for treating this condition. Many women bleed to death, not from the vessels in the placenta previa, but from lacerations in the cervix or at the point of implantation of the placenta. These can be prevented by vaginal section. He also considers it useful as a means of artificial delivery in case of an absolutely torpid uterus. Vaginal cesarean section exposes to less dangers than days of ineffectual maneuvers to arouse the torpid uterus to action. In the total of 39 cases of vaginal cesarean section which he tabulates, the mortality was 8, and in 3 of these the death was due undoubtedly to the coincident eclampsia and in 2 others to heart disease. Anemia, peritonitis and sepsis from the dead fetus were noted in the other fatal cases. The cesarean section was undertaken on account of carcinoma in 23 cases, and of eclampsia in 6.

80. **Primiparae Under 16.**—Palotai has observed 25 cases of childbirth under 16, a proportion of .145 per cent. of 8,054 primiparæ admitted to the Budapest Frauenklinik. Among them were 7 who were only 14, and 18 who were 15 years old. One of the 14-year-old mothers had been blind from birth, another had been violated, and 2 others had never menstruated. In the others menstruation had occurred from once to five times. The course of the pregnancy was normal, but abortion occurred once, and delivery was premature in 28 per cent., but was exceptionally brief in all, and all the children were viable. The puerperium was normal, the prognosis for injury of the parts during delivery is very good and also the prognosis for the welfare of the child. When Nature confers the possibility of conception she evidently makes arrangements for its consequences to follow without hindrance.

81. **Amenorrhea of Girls Old Enough To Be Sexually Mature.**—Pincus thinks that this field is too much neglected. When the amenorrhea is long continued, even without symptoms, internal exploration is indicated in case of preceding infectious diseases or constitutional anomalies, menstrual molimina or vicarious hemorrhage.

82. **Septic Mastitis.**—Bensinger's patient was ii-para, 30 years old, healthy and with no morbid antecedents except a severe febrile reaction to an insect sting nearly two years before. The birth and puerperium were normal, and the patient was tended by a superior nurse. The eleventh day symptoms of mastitis developed, and the nursing babe was weaned. The babe developed the second day a phlegmonous inflammation behind the ear, and died the third day with multiple small cutaneous abscesses. The mother died two weeks after the first symptoms of the septic mastitis, with multiple suppurative foci. In seeking for the cause of the infection, an old, dirty book from a circulating library was found in the bed. The patient had been in the habit of reading while nursing her babe. Bacteriologic examination of the leaves of the book disclosed numerous streptococci, associated with other microörganisms. Bensinger also refers to the possibility that the blood poisoning from the insect sting may have left some latent focus. The nurse had tended a scarlet fever patient six weeks before being called to this case, but all her patients in the interim had been "normal cases." The sequel to the case was a defamatory letter sent to the physician by the sister of the deceased, for which she was condemned by the local court to a fine of $63 and costs.

83. **Cause of Sex Determination.**—Schultze argues to prove that the sex of the ovum is already settled in the ovary.

85. **Advantages of Ether.**—Pfannenstiel proclaims that the correct technic for an ether narcosis is to induce a tipsy condition with a small amount of ether, the "ether-Rausch," then slight intoxication from the carbon dioxid of the expired air, and thereafter, with a regular supply of weak ether fumes, maintain the narcosis at the proper point, raising the mask from time to time so that a little atmospheric air may be breathed. By this method he finds 100 c.c. of ether sufficient for even protracted operations. The mouth, throat and nose are rendered as aseptic as possible before commencing, which reduces the danger of pneumonia, and the room is kept very warm and every effort made to avoid chilling the patient on his way to and from the operating room. He aids the elimination of the ether by inducing diuresis and sweating. If drinking of fluids causes vomiting, this is regarded as an aid in the elimination. He also has water injected per anum.

Ether leaves the body much more rapidly than chloroform. With these precautions, he considers ether as almost completely harmless, while chloroform is always a serious poison.

87. **Extra-Uterine Pregnancy with Living Child.**—Sittner adds 16 more cases to the 126 he collected and published in the Landau *Festschrift;* 3 of them date since 1900. The mortality was 15 per cent. in the 40 cases occurring between 1896 and 1900. In one of the latest series the placenta had developed on the peritoneum and liver. The placenta was left. The patient died. In one the placenta developed on the intestines and in three on the organs in the pelvis. The mortality was very high in these and in the similar cases previously described. Four of the eight viable children are living. One died three weeks later of a gastro-intestinal trouble, and three others in from two to sixty hours. The fetuses weighed from 3,500 to 5,000 gm. on an average. The results of Sittner's compilation indicate that the possibilities of well-developed, viable children under these circumstances are greater than hitherto accepted. In seven cases the mothers were supervised and the pregnancy carried from the fifth, sixth or seventh month to three weeks of term, thus securing viable children. In the majority of cases extra-uterine pregnancy is followed by permanent sterility, but not always. There was subsequent normal pregnancy in eight out of twenty-five cases followed to date. He gives the particulars of the last series of cases in a convenient tabular form.

88. **Endothelioma Ovarii.**—Lange describes a case of endothelioma of one ovary which he extirpated, leaving the apparently sound mate in place. But the further course of the case proclaimed that the other ovary was likewise the seat of malignant disease. He therefore recommends as a routine procedure the removal of the second ovary in such cases, especially if the patient is 40 or over.

92. **Extramedian Symphysiotomy.**—Pestalozzi has applied in two cases Gigli's extramedian incision for opening the pelvis, described in THE JOURNAL of July 26, 1902, p. 231. Comparing the results with seven previously treated by the classic symphysiotomy, he considers the new operation a great progress. Healing was rapid and perfect without drainage, and the loss of blood was trifling, while consolidation occurred with remarkable promptness. He found it necessary to insert his finger behind the bone to prevent injury of the bladder in introducing the saw.

93. **Regional Lymph Glands in Uterine Cancer.**—Wertheim found in two-thirds of his cases of cancer of the uterus in which the lymph glands were involved, that the glands exhibited a polymorphous cellular construction. In the other one-third, however, the glands showed a tube-shaped formation lined with a single layer of ciliated epithelium. These formations were observed in 13 per cent. of all the cases that came to operation, but examination of 80 cadavers free from uterine cancer failed to disclose anything of the kind. In three instances it was possible to behold the direct transformation of a gland thus affected into a typical alveolar carcinoma, with polymorphous cells. The formations in question must, therefore, be considered metastases of the malignant neoplasm in the uterus.

94. **Disadvantages of Ventrofixation.**—Gradenwitz expresses gratitude to Kreutzmann for his denunciation of ventrofixation, referred to in this column. The smoothness and facility of the operation do not compensate for the consecutive metritis or hernia, as he illustrates by five typical cases.

98. **Influenza in Relation to Surgery.**—Perez has been making extensive researches on animals in the way of immunization against the influenza bacillus and study of the lesions produced by the infection. He says there is scarcely an organ or tissue that may not be attacked, and the local processes range from hyperemia to abscess formation or effusion. The tympanum is the most frequent site of experimental infection. He found that he was able to induce a slight and transient active immunity. The bacilli were almost invariably found intracellular and the pus was also frequently sterile. Another point to differentiate pure influenza infection from the pneumococcal is the presence of fibrin in the latter. He also reviews 520 articles that have been published on the surgical aspect of influenza.

101. **Prognosis of Carcinoma of Mamma.**—Merkens regards all new growths in the mamma as suspicious, with the sole exception of Schimmelbusch's fibro-adenoma. Ablation of the nodule is sufficient in case of the latter. All others should be considered malignant and amputation of the breast follow the diagnosis. He scouts the idea that cancer is directly contagious.

103. **Traumatic Rupture of Heart with Subacute Course.**—Ebbinghaus warns that the prognosis should be guarded in case of traumatism affecting the left thorax, even when the walls are elastic and no serious injury is apparent; death may result as late as the ninth day, as in the case he describes. The rupture at first was probably merely a partial laceration of the heart wall, but it gradually became a complete rupture as the region of the lesion became degenerated. The vagueness of the manifestations on the part of the heart is no criterion that the danger is past. The tear may gradually grow larger without causing appreciable clinical symptoms. In his case the left ventricle was the site of the rupture, and the pulmonary valve had also been injured.

107. **Formalin in Treatment of Purulent Otitis Media.**—Geronzi reports the results of formalin treatment of 55 cases of chronic purulent otitis media. He commenced with a 2 per cent. glycerin solution and gradually increased the strength to 5 per cent. The middle ear was tamponed with a small strip of gauze impregnated with the fluid, or two or three drops of the 5 per cent. solution were instilled. This treatment was applied only in those cases that had proved rebellious to ordinary measures. Improvement was manifest by the second or third application; and a complete cure between the tenth and fifteenth application was obtained in 34 out of the 55. The duration of the affection in some of the cured cases was from ten to twenty-one years. The formalin reduced the size of the granulations in the tympanum and, supplemented by nitrate of silver, was able to accomplish their complete disappearance in a number of cases. He found that the addition of 5 per cent. of sodium carbonate to the 5 per cent. solution of formalin increased the tolerance, while others have proved that it also enhanced its bactericidal power.

111. **Laryngeal Chondro-Perichondritis.**—Arias concludes his comprehensive study of this subject by recommending prompt tracheotomy, which not only insures the respiration but also leaves the affected parts in repose. It may be possible to abort the abscess, as was accomplished by Ferreri with a course of salicylic medication, followed by subcutaneous injections of iodated milk, as recommended by Sclavo. The patient was a boy of 10, with chondro-perichondritis of the left half of the larynx. Tracheotomy was postponed from day to day, as there were no indications of an abscess, and improvement continued under this treatment. The lad was dismissed in four weeks with no further traces of tumefaction. If an abscess has formed, tracheotomy is the only treatment. In case of subsequent stenosis, Schroetter's method of intuba-

tion is in use in the Italian clinics. Serum therapy has always proved disastrous in tubercular inflammation, but the course of the affection may be arrested with the use of adrenalin. He has witnessed complete cures under supplementary hygienic and prophylactic measures. It is very important, however, particularly in these cases, to place the organ in repose by means of an early tracheotomy. Even in case of syphilitic inflammation a tracheotomy aids the healing process and the patient can be dismissed sooner. The prognosis of typhoid perichondritis is grave. It always entails an abscess, and Bayle had only 1 out of 17 recover without operation, Valleix only 6 out of 31, while Obédinaire cured 13 out of 24 by surgical intervention. If an abscess ruptures spontaneously the pus invades the bronchi and lungs with various sequelæ. Primary chondritis is acute; the secondary has a more chronic course. The dyspnea increases during sleep; the interspaces and epigastrium sink in during inspiration; the veins of the neck are turgid, and the superficial venous network of the thorax is visible. In the acute form the symptoms may suggest edema of the larynx. There is likewise more or less inflammatory paralysis of the posterior cricoarytenoid muscles. The cricoid cartilage is most frequently involved. Attacks of gout elsewhere may suggest the possibility that the perichondritis may be of the same nature.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

MANTON'S OBSTETRICS. A Manual of Obstetrics for Students and Practitioners. By W. P. Manton, M.D., Adjunct Professor of Obstetrics, and Professor of Clinical Gynecology, Detroit College of Medicine. Pp. 265. With 82 Illustrations. Cloth. Price, $1.00. Philadelphia and New York: Lea Brothers & Co. 1903.

FORTY-SEVENTH ANNUAL REPORT OF THE EXECUTIVE COMMITTEE OF THE HARTFORD HOSPITAL, Including the Eighteenth Annual Report of the Old People's Home and the Twenty-fifth Annual Report of the Hartford Hospital Training School for Nurses. Paper. Pp. 115. Hartford Press. 1902.

TOXICOLOGY. The Nature, Effects and Detection of Poisons, with the Diagnosis and Treatment of Poisoning. By Cassius M. Riley, M.D., Professor of Chemistry and Toxicology in Barnes Medical College. Cloth. Pp. 132. Price, $1.50. St. Louis: Lewis S. Matthews & Co.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Feb. 14, 1903:

P. A. Surgeon E. J. Grow, detached from the *Marblehead* and directed to wait orders.

P. A. Surgeon W. L. Bell, detached from the naval hospital, Mare Island, Cal., and ordered to the *Marblehead*.

P. A. Surgeon R. W. Plummer, commissioned passed assistant-surgeon, with rank of lieutenant, junior grade, from June 17, 1902.

Asst.-Surgeon R. E. Briggs, appointed assistant surgeon, with rank of lieutenant, junior grade, from Jan. 19, 1903.

Asst.-Surgeon R. L. Sutton, F. W. S. Dean, appointed assistant surgeon, with rank of lieutenant, junior grade, from Jan. 20, 1903.

A. A. Surgeon W. H. Block, ordered to the naval recruiting office, Chicago.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Feb. 12, 1903:

Surgeon G. M. Magruder, granted leave of absence for one day.

Asst.-Surgeon C. E. Decker, granted leave of absence, on account of sickness, for ten days.

Asst.-Surgeon H. B. Parker, to proceed to New Orleans, for special temporary duty.

A. A. Surgeon H. J. Hamilton, granted leave of absence, on account of sickness, for thirty days from Dec. 27, 1902; granted fifteen days' extension of leave of absence, on account of sickness, from January 27.

A. A. Surgeon H. C. Sibree, granted leave of absence for six days from February 7.

A. A. Surgeon C. F. Ulrich, granted leave of absence for twenty-five days from February 15.

Pharmacist Henry Gahn, granted leave of absence for five days from Feb. 6, 1903, under provisions of Paragraph 210 of the regulations.

RESIGNATION.

A. A. Surgeon Pedro Malaret, resigned, to take effect Jan. 31, 1903.

BOARD CONVENED.

Board convened at Washington, D. C., Feb. 9, 1903, to consider an outline plan for the marine-hospital to be erected at Savannah, Ga. Detail for the Board: Assistant Surgeon-General J. H. White, chairman; Assistant Surgeon-General L. D. Williams; Assistant Surgeon-General W. J. Pettus, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Feb. 14, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Feb. 6, 2 cases.
California: Los Angeles, Jan. 17-24, 4 cases; Sacramento, Jan. 24-31, 4 cases; Stockton, Jan. 1-31, 10 cases.
Colorado: Denver, Jan. 17-24, 17 cases.
Illinois: Chicago, Jan. 31-Feb. 7, 16 cases; Galesburg, Jan. 24-31, 5 cases.
Indiana; Indianapolis, Jan. 17-24, 152 cases, 36 deaths.
Maine: Biddeford, Jan. 31-Feb. 7, 16 cases; Eastport, Jan. 31, 7 cases.
Maryland: Baltimore, Jan. 31-Feb. 7, 4 cases; Cumberland, Jan. 24-31, 1 case.
Massachusetts: Jan. 31-Feb. 7, Boston, 6 cases; Haverhill, 1 case; New Bedford, 1 case.
Michigan: Detroit, Jan. 24-31, 43 cases; Grand Rapids, Jan. 31-Feb. 7, 14 cases.
Missouri: St. Louis, Jan. 24-Feb. 1, 26 cases.
Nebraska: South Omaha, Jan. 1-31, 1 case.
New Jersey: Camden, Jan. 27-Feb. 3, 2 cases; Newark, Jan. 31-Feb. 7, 2 cases.
New York: New York, Jan. 31-Feb. 7, 2 cases.
Ohio: Cincinnati, Jan. 30-Feb. 6, 11 cases, 1 death; Dayton, Jan. 31-Feb. 7, 6 cases; East Liverpool, Jan. 1-31, 2 cases; Hamilton, Jan. 1-31, 5 cases; Toledo, Jan. 10-31, 19 cases.
Pennsylvania: Altoona, Jan. 31-Feb. 7, 1 case; Philadelphia, Jan. 31-Feb. 7, 33 cases, 2 deaths.
South Carolina: Greenville, Jan. 24-31, 1 case.
Utah: Salt Lake City, Jan. 24-31, 19 cases, 1 death.

SMALLPOX—FOREIGN.

Austria: Prague, Jan. 3-17, 14 cases.
Barbados: Jan. 2-16, 4 cases.
Belgium: Antwerp, Jan. 3-17, 10 cases, 3 deaths.
Brazil: Rio de Janeiro, Dec. 27-Jan. 10, 9 deaths.
Canada: Winnipeg, Jan. 1-31, 2 cases.
Canary Islands: Las Palmas, Dec. 27-Jan. 17, 31 cases, 1 death.
Germany: Altona, to Jan. 22, 11 cases, 1 death.
Great Britain: Birmingham, Jan. 17-24, 5 cases; Leeds, Jan. 10-24, 19 cases; Leith, Jan. 10-17, 2 cases; Liverpool, Jan. 17-24, 51 cases, 1 death; Nottingham, Jan. 3-10, 1 case; Sheffield, Jan. 10-24, 3 cases.
Mexico: City of Mexico, Jan. 18-25, 5 cases, 2 deaths.
Russia: Moscow, Dec. 27-Jan. 3, 1 death; Odessa, Jan. 3-17, 12 cases; St. Petersburg, Jan. 3-10, 49 cases, 6 deaths.
Straits Settlements: Singapore, Dec. 20-27, 3 deaths.
Turkey: Constantinople, Jan. 4-11, 3 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Dec. 27-Jan. 10, 56 deaths.
Mexico: Tampico, Jan. 18-31, 3 deaths; Vera Cruz, Jan. 24-31, 6 cases, 3 deaths.

CHOLERA—FOREIGN.

Egypt: Alexandria, Jan. 12-19, 4 cases, 3 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Jan. 29-30, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Dec. 27-Jan. 10, 6 deaths.
Mexico: Mazatlan, to Feb. 4, 278 cases, 217 deaths.

Original Articles.

LARYNGECTOMY FOR CARCINOMA.*

E. FLETCHER INGALS, M.D.
CHICAGO.

The text for this article was furnished by a patient who was brought to our clinic for diseases of the chest, throat and nose at Rush Medical College by Dr. Geo. A. Torrison, who had found him among his patients about six months previously. Dr. O. T. Freer had also seen the patient with him and a microscopic examination of a small mass removed for the purpose had confirmed their diagnosis of carcinoma of the larynx, which diagnosis was also concurred in by Prof. L. Hektoen.

THE PATIENT AND HIS HISTORY.

The patient, L. T., was a large, fine-appearing man, 47 years of age, who came to this country from Norway thirty years ago. He weighed about 200 pounds and had every appearance of robust health excepting the one symptom of hoarseness. He was a jeweler by trade, married and had three healthy children. He stated that he had malaria for three months seventeen years ago, had an attack of typhoid fever and also a slight attack of pneumonia some years ago, and in November of last year a rheumatic affection of the left thigh for a few days, which was followed by another slight pneumonia. Excepting these he had never been sick. He denied specific taint and there was nothing to cause us to question this statement. His mother died of old age at 83, father living at 83 in good health, two brothers and one sister living and well, aged respectively 56, 51 and 49.

The patient was a user of tobacco and alcoholic stimulants in moderate quantities, but had never been given to excess of any kind. There was nothing in his personal history to indicate the cause of the disease and there was no hereditary history of syphilis, malignant disease or tuberculosis. The hoarseness began eighteen months previously; it had gradually increased for twelve months, or until he came under the care of Dr. Torrison, six months before I saw him. At first, although the true nature of the growth was suspected, the diagnosis was in doubt, and the doctor wisely put him on iodid of potassium, under the influence of which the voice gradually improved for two months. When first seen by Dr. Torrison there were two smooth white nodules involving the middle third of the left vocal cord, attended also by some swelling or thickening of the ventricular band immediately above it. In November, 1901, the growth showed considerable increase in size and had already spread to the anterior end of the right cord, but there was no glandular enlargement.

THE PRELIMINARY TRACHEOTOMY.

On his first presentation at our clinic in the latter part of January, I found a growth of comparatively small size involving all of the left cord, giving it an irregular edge with a rough, slightly ulcerated surface, and increasing its size irregularly about four times. The false cord was also thickened and the right side was involved to about one-third this extent. There was no glandular involvement. I told the class that while I believed that, as a rule, patients with malignant growths in the larynx would live longer and suffer less from a simple tracheotomy than from laryngectomy, yet in this case the conditions were so favorable that I advised the latter operation. The patient was admitted to the Presbyterian Hospital February 4, and the next day at the college clinic I did a preliminary tracheotomy under cocain anesthesia. The patient made an uneventful recovery from this operation, and at my clinic on February 26 was again operated on by the late Prof. Christian Fenger, who did a laryngectomy, which proved to be the doctor's last operation, as he died of pneumonia about a week later.[1]

PROFESSOR FENGER'S CLINICAL REMARKS.

I am greatly indebted to Dr. Karl Doepfner, Professor Fenger's assistant and associate instructor in surgery, for the report of Professor Fenger's remarks on this occasion, and to Dr. Otto T. Freer, instructor in diseases of the chest, throat and nose, for the clinical report of the operation.

Because of the comparatively small growth, absence of enlarged glands and its intrinsic character, I hoped that J. Solis-Cohen's operation might be performed, but after opening the larynx Professor Fenger found that the growth had perforated its walls; therefore, complete laryngectomy was the only operation to be considered. Before coming to the operation Professor Fenger spoke as follows of the history of this procedure, its results and the various indications for removal of this organ, illustrating his remarks with numerous free-hand chalk illustrations on the blackboard, which, unfortunately, I am unable to reproduce. Professor Fenger said:

THE HISTORY OF THE OPERATION.

Regarding the history of this operation in 1829 Albers of Bonn did experimental laryngectomy on dogs for physiologic purposes, but surgery was not yet advanced enough to make practical use of his investigations. In 1854 Bernhard von Langenbeck of Berlin intended to do it, but the patient refused the operation. In 1856 Koeberle also pointed out its feasibility. In 1866 Watson of Edinburgh performed the first total

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. J. F. Barnhill, C. R. Holmes and G. H. Makuen.

1. EDITOR'S NOTE.—This paper is published on the anniversary of Dr. Fenger's death, which occurred March 7, 1902.

extirpation for syphilitic stenosis. In 1870 Czerny made successful experiments on dogs for the purpose of surgical intervention in man, whereon in 1873 Billroth for the first time totally removed a carcinomatous larynx. Up to the end of 1897 we find in the literature 267 cases of total laryngectomy. Since then many more cases have been published.

POINTS OF ORIGIN OF CARCINOMATA.

It is important to distinguish between intrinsic and extrinsic carcinomata of the larynx.

Intrinsic carcinomata may originate from the true cords, the false cords, the interarytenoid folds, the ventricles of Morgagni or the subglottic space.

Extrinsic carcinomata spring from the epiglottis, posterior wall of larynx—pharyngeal surface (out of 18 cases this point of origin has been found 13 times), the ary-epiglottic folds and the sinus pyriformes.

J. Sendziak, to whom we owe the most recent and best statistical work, gives the following data: Out of 273 cases where the point of origin could be located beyond any doubt, the carcinomata were intrinsic in 204 cases or in 74 per cent., and among these cases the true cords were 107 times the primary seat of the affection. This means that the carcinomatous new growth in the larynx attacks by preference the parts covered with squamous epithelium. Consequently, the squamous-celled carcinoma is the predominant variety in the larynx, while the cylindrical-celled and the glandular (adeno-) carcinomata are less common. It means also that wherever the intrinsic carcinoma starts it follows in its propagation the squamous-celled surface. In other words, it spreads from one side to the other, most frequently along one cord to the commissure and then to the other cord (circular carcinoma).

Early regional infection of the neighboring lymph glands is not always manifest. It is more common in the later stages of the disease, and yet more frequent in the extrinsic carcinoma. This peculiarity is said to be due to the scarcity of lymph vessels in the walls of the laryngeal cavity proper. Metastases in remote organs have been observed in but a few cases. We may, of course, occasionally see a secondary carcinoma in a larynx, which had its primary seat in some neighboring organ, base of tongue, pharynx, thyroid gland, trachea, esophagus.

ETIOLOGY.

The etiology is unknown. Carcinoma of the larynx is much more frequent beyond the age of 40 (84 per cent.). Out of all cases published 39 per cent. occurred between the fifth and sixth decade of life, which is the most dangerous period. It is six times more frequent in men than in women. The disease is fortunately rare. Gurly in his tumor statistics, pointed out that out of all carcinomatous growths only 0.5 per cent. are located in the larynx.

THE THREE STAGES OF THE DISEASE.

Three stages of the disease are described:

Intrinsic Carcinoma.—1. In the stage of irritation there exists chronic hoarseness, which, according to Gerhardt, when occurring without cough in old people always suggests carcinoma of the larynx. Paresis or paralysis of one cord may also be present.

2. The ulcerative stage will be accompanied by fetor, cough, expectoration of muco-purulent, bloody, necrotic masses, and beginning dyspnea. We may or may not have pain either spontaneously, or on coughing or swallowing along the auricular branch of the pneumogastric nerve, radiating to the ear and occiput.

Extrinsic Carcinoma.—1. Here the first noticeable symptom will be dysphagia. This soon increases, and at the same time dyspnea may be noticed.

2. In the ulcerative stage, the symptoms are the same as in the intrinsic carcinoma.

3. The third or cachectic stage is common to both varieties—due to the lack of food (dysphagia), lack of oxygen (dyspnea), and sleeplessness caused by difficult respiration and pain. Death ensues in about three years after the onset of the disease, sometimes rather suddenly from suffocation or aspiration-pneumonia, sometimes slowly from cachexia and marasmus, due to the cancer and to the difficulty in taking food.

DIAGNOSIS AND PROGNOSIS.

I need not speak to you of the diagnosis, which has already been considered by Professor Ingals, but you should remember that macroscopic inspection is of more value in diagnosis than all other methods of examination, but do not forget that the reflected image in the mirror seldom reveals the full extent of the disease.

Microscopic examination of an excised particle of the new growth certainly is one of our best methods to clear up the diagnosis, but it is not infallible. Where it fails, and there is still strong clinical suspicion of carcinoma, we are justified in proposing and performing a laryngotomy. The diagnosis, however, is perplexing only in the early stages of the disease. The prognosis is hopeless without surgical intervention.

OPERATIVE TREATMENT.

According to our present knowledge, carcinoma should be extirpated wherever an operation is practicable. Carcinoma of the larynx may be extirpated by different operative methods.

1. *Endolaryngeal Operations.*—While benign tumors can usually be removed by endolaryngeal methods, and while even small malignant growths have been successfully removed in this way and the patients permanently cured, yet we must not put too much faith in such methods in operating on malignant tumors. We must always bear in mind that carcinoma is an infiltrating growth, infecting neighboring tissues which to the naked eye seem yet to be normal, and that it often spreads in the submucosa, leaving the mucosa healthy for a time at least. No doubt a skilful specialist will have good results if he sees such cases sufficiently early, but unfortunately this very seldom happens. Out of 640 patients—I quote from Sendziak—only 36 were treated by endolaryngeal methods with 25 per cent. absolute cures (3 years of observation), 14 per cent. relative cures (1 year of observation), 39 per cent. recurrences; in 22 per cent. the time of observation was too short or the diagnosis not absolutely established. All these cases came early under the treatment of skilful laryngologists and yet there were 39 per cent. recurrences. The following operative procedures must usually be preceded by a preliminary tracheotomy.

2. *Laryngotomy.*—We understand by this operation an incision, median or transverse, into the larynx through the skin with removal of soft parts only, not including cartilage. There exist at least 6 modifications of this operation. What are the results? Statistical figures may be annoying in a clinical lecture but they are instructive. Sendziak gives complete statistics up to 1894; to von Bruns we owe the figures from 1890-1898.

	1851-1894 (92 cases.) Per cent.		1890-1898 (60 cases.) Per cent.	
Cured more than three years	8.7	21.7	18.0	36.0
Under observation from one to three years	13.0		18.0	
Recurrence	53.3		28.0	
Death from operation	9.8		15.0	

That means bolder operating during the last decade, more cases, less recurrences, but also more deaths. All our big operations on the larynx must begin with a laryngotomy except where there is no doubt as to the bilaterality of the carcinoma. The larynx once split open and its interior laid bare for inspection and palpation—then only are we able to decide whether laryngotomy will do or whether we have to resort to partial or total laryngectomy. In the cases which may be treated by laryngotomy alone, the cartilages must be sound and no perforation must have taken place.

3. *Partial Laryngectomy.*—This, generally speaking, is a laryngotomy with more or less resection of soft parts and cartilage. It may be of half the larynx or more. There are different methods of doing this operation. The results are as follows:

	1876-1894 (110 cases.) Per cent.		1890-1898 106 cases.) Per cent.	
Cured more than three years	10.9	22.7	12.0	27.0
Under observation from one to three years	11.8		15.0	
Recurrence	30.0		31.0	
Death from operation	26.3		17.0	

This means distinctly more cures and less death-cases within the last ten years, but the same number of relapses due to the conservatism of the surgeons, in cases that were already too far advanced for partial laryngectomy. Radicalism in doubtful cases is safest in all cancerous growths.

4. *Total Laryngectomy.*—This consists in removal of the whole organ, with or without the epiglottis, and perhaps some of the adjoining tracheal rings and part of pharynx and esophagus. We must resort to it in all the cases of circular carcinomata and in most of the cases where the growth has become bilateral. Here are the results:

	1873-1894 (188 cases.) Per cent.		1890-1898 (81 cases.) Per cent.	
Cured more than three years	5 8	12 7	8 6	26.0
Under observation from one to three years	6 9		17.4	
Recurrence	32.4		23.4	
Death from operation	44.7		18.5	

During the last decade there are distinctly more cures, less relapses and many less deaths. What has brought about this improvement? Most of the patients formerly died from aspiration-pneumonia or wound infection (primary and secondary) even long after the general establishment of antiseptic wound treatment. The aspiration-pneumonia was combated:

1. By operating with the hanging head (Rose's position).

2. By the various tampon-canulas of Trendelenburg, Hahn, Koehler, and Gerster.

3. By suturing the stump of the trachea to the skin (Glueck and Zeller) instead of leaving it open in the wound.

4. By operating in the combined Trendelenburg and Rose's position and by keeping the patient in Trendelenburg's position for several days (W. W. Keen).

5. By loosening the trachea from the surrounding connective tissue, pulling it upward and suturing it to the epiglottis (if not removed), hyoid bone, lateral sides of pharynx (Foederl). This is an ideal operation where it can be done.

Phlegmonous inflammation of the wound has been most successfully prevented by closing the large pharyngeal opening (Bardenheuer). No longer saliva with its microbes could run down and infect the wound, and the external wound itself could be closed and very well drained in its dependent parts. By this method the patient can sometimes swallow immediately after the operation, although it may be more prudent to introduce a soft tube into the esophagus or resort to rectal feeding.

DEGLUTITION AND SPEECH AFTER OPERATIONS.

The restoration of the power of deglutition is of even more importance to the patient than restoration of the voice. After closure of the pharyngeal wound, patients are soon able to swallow, and if the sutures hold, nothing can enter the trachea. Before this plan was adopted patients were able to swallow solid and semi-solid food, but liquids would escape through the pharyngeal fistula into the trachea and cause cough, tracheitis or broncho-pneumonia.

After endolaryngeal operations, the voice will be more or less perfectly restored; after laryngotomy and partial laryngectomy, the voice will also usually return to such a degree that the patient can make himself understood. In Professor von Brun's celebrated case, the carcinoma affected one vocal cord. Ten years ago he removed it by performing a total laryngotomy—splitting open the larynx from the superior thyroid down to the trachea. A cord-like cicatrix formed at the place of the removed cord and the voice was restored so that the patient—a professor of clinical surgery—has ever since been able to deliver his clinical lectures.

After total laryngectomy the laryngeal voice is of course lost, but patients are able to whisper. Several different artificial larynges have been devised to overcome this difficulty, but most of the patients prefer whispering to carrying around such a rather cumbersome instrument. The whispering voice can be much improved by use, especially in the cases where the pharynx has been successfully closed. After the operative method where the trachea is stitched to the hyoid bone, and therefore opens into the mouth cavity, the patient not only has soon learned to swallow every kind of food, but has also developed quite a good so-called pharyngeal voice. By this method the patient also retains mouth and nasal respiration—a not unimportant physiologic function—while with other operations tracheal respiration with its inconveniences and dangers is persistent.

THE PATIENT AND THE OPERATION PROPOSED.

Our present patient has an intrinsic carcinoma as suggested by chronic hoarseness for eighteen months without cough and no wasting of the body as would occur in phthisis. The laryngoscope and the histologic examination substantiate the diagnosis.

The carcinoma is bilateral, consequently partial extirpation is no longer admissible, unless it be by the Solis-Cohen operation. This method is better than a simple hemi-laryngectomy as it takes away a part of the laryngeal skeleton of both sides. Professor Ingals hopes that this more conservative measure is yet practicable. A laryngotomy will allow us to carefully survey the larynx and determine the full extent of the disease.

A preliminary tracheotomy through the third, fourth and fifth cartilages was done three weeks ago, and the temporary tracheo-bronchitis has subsided. In this case blood will be prevented from flowing into the trachea by the sponge canula of Hahn, which I prefer to Trendelenburg's canula. The rubber bag of the latter is liable to collapse, or to distend below the end of the tracheotomy tube so as to cause suffocation.

OPERATION.

After insertion of the Hahn canula, through which chloroform was administered, Professor Fenger began his operation by making an I-shaped incision, the upper transverse cut following the hyoid bone, the lower one a line below the cricoid cartilage. The vertical incision was made in the median line. The two flaps thus outlined containing the skin, superficial fascia and prelaryngeal muscles were held aside. A curved needle was next passed under the hyoid bone, which was then pulled forward by a strong silk ligature. This brought the laryngeal region into strong relief, the thyroid, cricoid cartilages and trachea lying bared to view. The larynx was next opened in the median line, the thyroid and cricoid cartilages being split vertically and the thyrohyoid membrane severed from the hyoid bone. At the anterior inferior angle of the right quadrilateral plate the thyroid cartilage was found very thin, and when touched with a probe broke down before it, yellow carcinomatous material in a state of fatty degeneration oozing out. This condition and the fact that the growth was found to have involved the anterior half of the other cord made Professor Fenger decide that total laryngectomy was necessary. He called attention to the fact that the laryngoscopic appearances gave no proper idea of the great extent of the disease. Though no enlarged lymphatic glands could be detected, he thought that the best course would be to follow the laryngectomy in about six weeks by an operative search for lymphatic metastases in the carotid and submaxillary regions.

The patient was now lowered into an extreme Trendelenburg position, the body being inclined at an angle of 45 degrees so that in addition to the tampon canula the position of the patient with the head downward made it impossible for blood to enter the trachea or for the saliva to flow into the wound. The patient's heart at this time began to beat very slowly and it finally stopped for a few seconds, but he was revived and the operation finished without further anesthesia. Contrary to the usual practice, Professor Fenger began the removal of the larynx by severing it from its attachments at its upper part, as this gave a better chance to treat the pharynx and esophagus conservatively because they could thus be brought into view and separated more carefully from the larynx. It also gave great freedom of motion to the larynx and made it possible to lift it from its bed and twist it so as to expose the lateral portions in order to reach the vessels at its side. These

were the superior laryngeal, superior thyroid and inferior laryngeal arteries. The vessels were divided between two artery forceps and each severed portion tied. Working downward in this manner on both sides the larynx was carefully dissected from the pharynx and esophagus and then drawn forward and removed from its attachment to the trachea.

After the larynx had been removed it was found that the growth had extended close to the base of the epiglottis, which had been left with the intention of using it for closing the wound in the pharynx. Because of the nearness of the carcinoma it was thought safest to sacrifice the epiglottis. The opening into the pharynx and esophagus was now closed by sutures from above downward, thus completely restoring the pharyngeal tube. The severed end of the trachea was brought out of the wound and stitched to the skin where the lower transverse incision met the median incision. The skin flaps were turned in and sutured, care having been taken that every nook and corner of the wound was properly drained. Hahn's canula was removed and the old canula replaced. No blood had entered the trachea around the sponge. Catgut was used for the ligatures and pharyngeal sutures. The knots were tied inside the pharynx. Moist boric acid dressing was used.

The recovery was uneventful, except that on the fourth day the esophageal tube was retched up by the patient and on the same day a communication formed between the pharynx and the wound from sloughing away of the anterior wall of the pharynx. This untoward event afterward prevented the patient from swallowing liquid food, which would escape through the pharyngeal fistula. Whether this fistula will close spontaneously in a few months or be closed by a plastic operation remains to be determined.

Dr. Fenger concluded that it would be better not to use a permanent esophageal tube for feeding, but to nourish the patient by rectum for a few days and afterward to teach him to swallow liquids, for this purpose using sterilized milk, or if this did not succeed an esophageal tube should be used for a time at each feeding.

34 Washington Street.

DISCUSSION.

Dr. T. R. Chambers, Jersey City, N. J.—I wish to speak of two points. The first is the assertion made that when you have cancer you must take it away. I think that is liable to be misunderstood. Personally, I think I would rather die, if I had cancer of the larynx, than to have to suffer with the growth only partially removed. Its return would mean a great deal more agony to me than the few months or possibly only a few hours of life after a major operation like laryngectomy. The Doctor then says that a major operation on the larynx must always be preceded by tracheotomy. I do not know whether he considers an excision of the epiglottis near its base as a major operation, but last Friday I removed the epiglottis at its base for cancer of the epiglottis and the patient did very nicely, although no tracheotomy was done. I think I would remove cancer in its very incipiency, if possible.

Dr. O. T. Freer, Chicago—Dr. Fenger did not advocate tracheotomy as a preliminary to all total or partial laryngectomies, but advised it where there is uncertainty as to the extent of laryngeal carcinoma, that is, in those cases where partial laryngectomy or laryngotomy may perhaps suffice to eradicate the disease, and preliminary laryngotomy is therefore done to determine whether the larynx may be in part preserved or needs total removal.

Where total laryngectomy is contemplated from the start and dyspnea is not urgent, it is better to remove the unopened larynx without preliminary tracheotomy, as this creates a suppurating wound with surrounding inflammation, and a cleaner, neater dissection can be done without it. In addition, the presence of a tube in the trachea leads to coughing fits that add to hemorrhage and interrupt the operation. In total laryngectomies of this type it is better, therefore, not to open the trachea or larynx at all. In distinction to this, partial laryngectomy, even if merely contemplated as a possibility, necessitates laryngotomy and consequent bleeding into the lumen of larynx and trachea. This hemorrhage may be severe and hard to control, while that occurring in total laryngectomy is easily arrested and reached. It is therefore well to insert a sponge tampon canula into the trachea in cases of contemplated partial laryngectomy, though it is not a necessity, as Rose's position will usually answer to keep the trachea free from blood. The tampon canula insures against aspiration of blood upward into the trachea and its clotting there and makes the extreme Rose's position unnecessary, and this is an advantage, as the position with inverted head adds much to bleeding and is uncomfortable for the operator.

Cocain is always to be first applied to the trachea through the tracheotomy wound to avoid the coughing due to the presence of the tampon canula.

Dr. Norval H. Pierce, Chicago—I think it is important in all cases to do a preliminary tracheotomy before either a partial or complete removal of the larynx. Not only does this give us breathing space during the operation and prevent the entrance of blood into the larynx, but in the after-treatment the discharges are cut off from the trachea, and thus the most frequent cause of death, aspiration pneumonia, is largely avoided. I have seen Fenger perform the operation three times, and in all of those cases he made a preliminary tracheotomy.

I would like to put on record a case which illustrates very nicely the difficulty of diagnosis of carcinoma of the larynx in its early stages. A Canadian clergyman was stopping in the city, and a friend advised him to consult me regarding a hoarseness which had lasted some six months. He was obliged to give up his work because of this hoarseness; his physician advising rest as a cure. The laryngeal picture was as follows: On the right cord below its surface was a nodule, pinkish in color, but well defined, with no induration around its base and no redness of the cord, except possibly a slight pinkish color of the upper surface above the growth. It was the size of a small split French pea or even smaller. I removed this growth as well as I could through the natural way, and was surprised, on microscopic examination, to find evidences of sequestration of epithelial cells. This case, immediately after the operation, assumed a malignant character. The induration increased so that after five days the entire picture was changed, the hoarseness was greatly increased, and it came to the point where I advised him to have an external operation performed. Greatly shocked, and not at all friendly toward me, he returned to his home in Canada, where I have heard that he is steadily going down. Now here is a case in its incipiency where I was misled in my diagnosis, thinking it to be a simple papilloma, and I am sure no one could have made the differentiation by the microscopic appearance at that time.

Dr. Peter J. Gibbons, Syracuse, N. Y.—I notice in the abstract that the patient was able to speak. I did some work registering on the phonograph the voice of Dr. Solis Cohen's first case. I registered on the cylinder of the phonograph what he could say and how it sounded and repeated the examination every three or six months or a year. At the meeting in Philadelphia I reproduced them. I have used the phonograph to register other cases since then, and I have come to use it frequently. In a case in which a physician was sued for malpractice for the removal of a tonsil, I used the phonograph for the registering of the voice, which won the case for the doctor. By registering the voice of the patient on the phonograph, we encourage other patients, who can hear the records when an operation is contemplated. The patient will often consent to an operation when he would not, prob-

ably, if he did not hear the reproduction of the voice. It is a simple matter to register the voice in this way.

Dr. E. Fletcher Ingals, Chicago—In reference to whether carcinoma should be operated on or not, I simply gave the late Professor Fenger's views. I am, personally, heartily in sympathy with what the Doctor said; I should not usually have laryngectomy done for carcinoma. In all my experience I have only seen a single case in which laryngectomy seemed to me justifiable, and that was the one here reported. In the presence of cancer I believe the majority of cases will live longer and more comfortably without laryngectomy than with it. Professor Fenger believed that tracheotomy was not desirable in some cases. In this case I had done tracheotomy myself beforehand, without consulting Dr. Fenger about it. The case referred to by Dr. Freer was operated on by what is sometimes called Keen's operation, without a previous tracheotomy. It is turning out very satisfactory, and if other cases do as well, preliminary tracheotomy would not often be necessary.

THE ASCH OPERATION FOR DEVIATIONS OF THE CARTILAGINOUS NASAL SEPTUM: WITH SOME CONDITIONS COMPLICATING ITS PERFORMANCE.*

EMIL MAYER, M.D.
NEW YORK CITY.

There are many varieties of deviation of the cartilaginous nasal septum. In some the occlusion is complete, in others partial, some are high up while others are close to the floor. In some there are adhesions resulting chiefly from previous attempts at their cure, principally caused by the use of escharotics, while in others the deviation of one side is associated with a dislocated columnar cartilage on the other, making it S-shaped; and finally diseased conditions may lurk behind the obstruction. The bony septum is likewise deviated at times.

The record of a few of the complications of septal deviations is here presented.

Case 1.— J. W., aged 17, was sent to the New York Eye and Ear Infirmary by one of our well-known laryngologists. His cartilaginous septum was deviated to the left. Occlusion was nearly complete, while on the right the columnar cartilage was dislocated, almost completely closing that side. His right nostril operated on by a dissecting operation with excision of the protruding end, the mucous membrane stitched together and in a fortnight the parts had healed firmly and a free current of air established on that side, thus relieving the dislocation of the columnar cartilage. Subsequently an Asch operation was performed and the result was a straight septum with perfect respiration.

Case 2.—E. S., male, 26 years old, suffering from complete obstruction of left nostril and periodic attacks of hay fever. The main points of an unusual nature in this case were the complete occlusion and many points of adhesion of the cartilaginous septum to the inferior turbinate and the exceeding thinness of the septum. Escharotics had been formerly applied. In this case a perforation resulted, but the breathing is free and unobstructed and the improvement in health marked.

Case 3.—Patient of Dr. C. S. Bull; male, aged 28; had applied to him for relief of a marked bulging of the left eye. The vision being normal, the bulging being prominent in the temporal and infraorbital regions, the diagnosis of an extrinsic tumor was made, which evidently caused the bulging. His nose was found to be obstructed, and at Dr. Bull's request I examined him. A complete deviation of the cartilaginous septum was found and it was utterly impossible to make any intranasal examination. I advised operation of his deviation to enable further examination, as a means for diagnosis. He was found to have a mitral regurgitant murmur and hence no anesthetic was given. Under cocain the Asch operation was performed and the result eminently satisfactory. A free field was opened for examination and no further intranasal obstruction found. With the restoration of breathing the bulging of the orbit diminished to a great degree, though it was still pronounced. The diagnosis of an osteoma of the orbital cavity was then made. The patient feeling so comfortable was averse to any operative procedure on the orbit and so was Dr. Bull.

A further series of cases might here be added for the relief of the bony deviations that occur so frequently. In all of these, however, the trephine, or the crushing instrument devised by Roe seems to be the most valuable of the means at hand, for details of which we refer to the writings of the originator.

In considering the accidents reported following the Asch operation we note that Robert Levy reports a case of death subsequent to the Asch operation, the cause of death being acute meningitis. The patient was an opium habitué, and his general condition so poor that any operative procedure would tend toward a fatal result, hence this operation could hardly be said to be the real cause of death in this case.

Stucky records injury to turbinates on the deflected side. The thought occurs, in trying to find a reason for the possibility of this, that the dull blade which is always introduced on the deflected side might have been made sharp by the instrument maker, otherwise its occurrence seems most difficult of explanation.

In a recent article on the "Correction of Deflections of the Nasal Septum with a Minimum of Traumatism," a new operation is presented, and the writer proceeds to demolish that of Asch. "Asch's procedure," says the author, "is intended to accomplish by force under narcosis in a few minutes, *without the aid of sight,* a result which can be attained only by the use of much more time and with the infliction of some pain by rhinoscopic methods."

As to the force required in the Asch operation, let us compare the writer's own method with that of Asch. The writer advocates the forcible removal of exostoses and crushing by means of the Roe forceps in an operation whose duration may be from thirty-five minutes to one hour and a half, under the local anesthesia produced by cocain in powder.

Asch cuts the cartilage in full ether narcosis, uses powerful compressors in the same unconscious state. Can any rhinologist picture the former method as being the gentler one? The most stoical of patients will surely moan as the former manipulations are being made, while the less determined will give vent to shrieks of pain of a heart-rending character as the crushing process is being performed; others again will go into collapse and give us a serious hour or two, if nothing more, from the action of cocain on the heart.

On the other hand, what surgeon hesitates to use force under ether to reduce a dislocation, to refracture a poorly-united bone, etc.? For this, anesthesia is humanity's boon and force can surely not be considered as an objection.

My own statement that "the Asch operation is one of magnitude" is quoted. The remark was made by myself in pleading for general narcosis and rest in bed and not as regards traumatism. The following instance, I am credibly informed, is by no means an unusual one:

Vigorous male, aged 32, septum deviated to right. Asch operation under cocain; tubes inserted and patient allowed to go home in an hour. Three hours later he was found exhausted and exsanguinated and hurried to a general hospital

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. Emil Mayer, C. R. Holmes and G. H. Makuen.

in an ambulance, where his tubes were removed, his nose packed and the bleeding checked.

When, at the end of a week, he left the hospital he had some pronounced views, let us hope, on the question of resting after such an operation.

I still hold the views formerly expressed; in one instance operation was delayed for over a year because I insisted on anesthesia and at least three days' rest. The patient finally consented, and has been grateful to me ever since for considering the operation of sufficient magnitude to require this.

The writer uses the words "without the aid of sight" as indicating the manner of operating, and here I must seriously challenge him to produce one single line from either the writings of Asch or of myself, or from the very clear description given by Shurly, Ingals, Coakley and others in their text-books as indicating that this operation should be done in such a manner. Indeed, the first great care is to have the broad light from a window, either direct or reflected, or else a properly shielded electric lamp; the Asch operation is done no more without the aid of sight than is an operation for adenoids or than with the Roe forceps, which I employ.

There are no two opinions regarding the question of the purpose of the Asch operation. It deals with the cartilaginous septum only. The bony septum can and always is cared for by means within our command.

As to the use of tubes after the operation: in the earlier operation packing was indulged in. This was very distressing to the patient and the tubes were the ultimate result of our efforts to support the broken septum in a proper position until the parts were firmly knit. In the hundreds of cases seen by me I know of few real complaints about the tubes—surely a few granulations can have no terrors to a skilled rhinologist—one sweep of a curette will end that. Compared to the comforts obtained, as against packing, of a properly fitting tube, there can be no doubt whatever.

That the Asch operation is of "growing popularity" is not due alone to the rapidity of its performance, but surely also to the results attained. To present the names of those who perform the operation to their own satisfaction and that of their patients would be to call a roll of many of those distinguished in their profession as rhinologists. To say that these advise and practice its performance because it is so simple a matter and not because it is in their opinion of the greatest good to their patients, is to make an unwarranted statement, to attack their intelligence and their surgical skill. Results and these only must count. Furthermore, no operative procedure, however simple, is free from unforseen and unhoped for complications, nor has there been any operation ever devised that will answer for every kind of deformity; nor can any operation hope to become popular which rests on the basis of attacking all others. In neither Asch's statements nor my own have other methods been attacked; it has sufficed us to say that the vast majority of deviations may be successfully cured by this method, and an experience of twenty years fully justifies that assertion.

The last word regarding any operative procedure is never spoken; the more popular it becomes the more frequently it is mentioned and assailed.

By our own mishaps and those of others we learn to avoid these and perfect our technic. Intelligent and fearless criticism is cordially welcomed, and it becomes incumbent on us to weigh these carefully and to answer them as best we may in the same cordial spirit.

25 East Seventy-seventh Street.

DISCUSSION.

DR. O. T. FREER, Chicago—I am the author referred to by Dr. Mayer. It is possible that, in my enthusiasm for the operative method advocated by me, I criticised the Asch operation with undue severity in contrasting it with my own mode of procedure. The operation that I prefer is that of the window resection, as it is named by Krieg, who was the first to give it a detailed description. Not knowing of the writings of Krieg and Bœnninghaus on the subject. I developed the operation independently in the course of my own work, as it seemed to me the most natural and proper one for a structure like the septum. The details of my method, therefore, differ somewhat from those of Krieg's proceeding, and much of my instrumentarium is original; both are described in my article in THE JOURNAL of the American Medical Association, March 8, 1902. Since this publication further experience has led me to make improvements which I hope to describe at some future time. The essentials of the method remain unchanged, however.

The resection operation consists in the removal of the cartilage and bone between the layers of mucous membrane lining both sides of the septum to the entire extent of the deflection. It is my experience that deflection of the bony septum usually continues that of the cartilaginous portion and that if the latter alone be straightened the patient will get but partial or no relief. The usefulness of the Asch operation is limited to the cartilaginous septum, therefore if the cartilage be straightened by it and the bone behind it be deflected or an exostosis be present this must be removed by a second later operation.

I agree with Dr. Mayer's objection to the Roe forceps. I included it in the instrumentarium described in my article, but further experience has led me to discard it. As Dr. Mayer has stated, the instrument often inflicts great pain, and for this reason and because it is impossible to tell with all fracturing procedures whether the break will occur in the desired place or not I have discontinued the use of the Roe forceps. In elastic septa it often failed to fracture at all, and sometimes would displace fragments in unexpected and undesired directions. Instead of fracturing, therefore, I now cut away all of the bony deflection as well as the cartilaginous. For this purpose I use cutting bone forceps, Gruenwald's strong nasal scissors, trephines and the chisel. A light, sharp chisel, with long bevel, impelled gently with light taps of a dental mallet will not fracture the septum beyond the field of operation. The instrument must simply be proportioned to the strength of the structure to be operated on. The use of a heavier chisel and mallet with strong malleting would be disproportioned to the resisting power of the septum and might break it. The light chisel cuts bone like a knife.

Dr. Mayer's description of the suffering I inflict on my patients has made me feel very sorry for them. The fact is that many of them chat with me while the work progresses and they often tell me that the resection of the cartilaginous part of the septum is quite painless. Trephining and cutting the bone causes more pain, but nothing that children of 12 and 14 have not borne without much complaint. Cocain anesthesia, therefore, makes the resection operation one of such slight suffering that I now boldly tell my patients that they will have but little to endure. All fracturing, however, or attempts to push over portions of the septum cause severe pain, as it strains distant portions not under the influence of the local anesthetic.

Faintness, as I have explained in my paper, seems associated with the first terror due to anticipation of the operation, and has invariably passed off in my experience after the work has gone on for a few minutes. It is not due to cocain, as in spite of the continued use of this drug, the faintness disappears.

The septum is a partition that consists of an elastic spring, the quadrangular cartilage, in front and a stiff bony plate behind. Less injury is done by complete exsection of the buckled part of this elastic spring than by attempts to force it into a straight line by its infraction. It takes greater force to break elastic than it does to break brittle substances, and

the result is apt to be imperfect. I therefore, from experience, ceased to attempt to deal with cartilaginous septal deflections by attempting to deprive them of their resiliency and relied on cutting them out as the most certain and mildest method. The cartilage or bone removed is of no physiologic importance, providing the mucous membrane be retained. It does not interfere with the support of the external nose. I have proven this often by extensive resections of the cartilage. Krieg has proved it, Bœnninghaus has also done so, as also have others. The accidents following the Asch operation are few and most of them may be due to chance, but I do not believe that it is as safe as the resection operation.

Dr. Mayer says that he uses sight in doing the Asch operation, and I apologize to him for stating that he does not. Nevertheless, I do not think that the Asch operation can be regarded as one where vision gives much aid, for, though the cutting may be done rhinoscopically, the fracturing certainly can not, and after the first cut the bleeding is too great to admit of useful vision.

The tubes employed in the Asch method are mildly irritating foreign bodies and, while usually harmless, are a source of discomfort and better dispensed with. After packing the naris for 2 to 5 days to avoid secondary hemorrhage, nothing is placed in the nasal fossa after the resection operation, as the naris operated on stands wide open, the deflection having been bodily removed.

The view of the interior structure of the septum offered me by complete excision of the deflection has shown me that deflections with walls of even, or nearly even, thickness are commoner than those with thickenings or exostoses. Many of the deflections, if merely sawed off by me, would have left in my mind the impression of exostoses.

One of the chief merits of the resection method is the fact that by it all of the deformity, bony and cartilaginous, may be removed at one sitting, radically and for all time, so that secondary operations are not needed.

There is no variety of deflection, whether thin or thick, complicated with exostoses, or ecchondroses or not, that can not be radically corrected by means of the resection method. It can not be done under a fixed rule, and the operator must be capable of modifications to suit the case and must have a sufficient assortment of instruments to cope with unusual obstacles, but if he gives heed to these conditions he will never fail to give the patient perfect breathing through the obstructed nostril when the operation is completed.

DR. C. R. HOLMES, Cincinnati—I would like to ask the Doctor if he uses the mallet and chisel.

DR. FREER—Yes.

DR. HOLMES—I do not understand the Doctor's method, and I would like to have him send me his reprints. I am afraid of chiseling on the bony septum. My lamented friend, Dr. Thorner, had one sad case in Cincinnati, where the use of the chisel was immediately followed by affection of the brain, and it was supposed that the death of the man was due to a fracture caused in this manner. Is it possible that drills can do the work?

DR. FREER—The trephine can do the work.

DR. HOLMES—Well, if the trephine could do the work, I think that would be much safer. If you study the skull, you will see how easily fracture may be caused, so that I would hesitate to use the chisel on the bony septum.

DR. C. F. THEISEN, Albany, N. Y.—In the cases in which the Doctor has to practice dissecting off the septum possibly back to the posterior nares, as he says is necessary sometimes, how is the nose supported?

DR. MAYER—The cartilages hold it in place.

DR. THEISEN—What if the individual receives a blow on the nose?

DR. MAYER—The cartilages will spring back the same as before.

DR. THEISEN—If the patient is under ether the operation is soon done and, in my experience, the patients do not complain of wearing the tubes after the first few days. They readily take out the tubes, cleanse them, and re-introduce them. In only one case have I had any trouble, and that was a case in which there was a small perforation before the operation. A small perforation resulted from the operation in one other case.

DR. P. J. H. FARRELL, Chicago—I have frequently performed the Asch operation and have been well satisfied with my results. I had the pleasure of hearing Dr. Freer read his paper on the operation devised by himself. I also have seen a number of cases after operation and the result in each case was very satisfactory. I will adopt the Freer operation in a series of cases on my return and will then have practical knowledge of both methods of operating for deviations of the cartilaginous nasal septum. I confess that I can see no good reason to quote men just simply to agree with them. I find it more instructive and interesting when an essayist has the courage to disagree with other writers. We all know that many of the papers read at medical meetings are simply a compilation. The bibliography frequently takes up more space than the subject itself.

DR. G. MCAULIFFE, New York City—Any discussion in reference to the bony portion of the septum should not be included in the discussion of the paper. Asch deplored the fact that his instrument was so badly manufactured and so poorly understood. The inability to get an exact right angle cross-section and the fact that the instruments are sometimes made with sharp points, will account for many unpleasant experiences. You can never make a straight line out of a curve, and I have found subsequently, after the Asch operation, there is a spur of bone in the lower portion, which necessitates subsequent sawing. As to the question of gentleness, if the operation is done thoroughly, the force necessary to run the finger up and break up the triangles (and it is necessary to break them up or they will spring out again), this procedure alone precludes the possibility of very great gentleness. But if the Asch operation is followed out according to its indications the result is good, except that you may have a spur to deal with subsequently.

DR. J. C. BECK, Chicago—I suppose the Doctor referred to me with the other men, for I told him that I did this operation. I attempted the operation on a man with a deflected septum very anteriorly. It was an ideal case clinically for the operation. In this particular case the operation was not difficult, and I used Adams' straightening forceps. The result was very good.

DR. J. E. BROWN, Columbus, Ohio—It seems to me this ought not to be a question of antagonism between, but simply a choice of, operations. We have here two operations, each with excellent features to recommend it to the surgeon. In a field of work much more limited than that of either of the essayists I have seen cases that I felt were not adapted to the Asch operation, and I have studied with much interest the method of Dr. Freer, and believe that in a certain line of cases it is to be preferred to the Asch operation. Under general anesthesia this latter is certainly not brutal, but the use of general anesthesia is certainly necessary for its satisfactory performance. I have twice made the operation under cocain, both times in the hospital, and it was in each case followed by more reaction than usual, and considerable prostration. In one case acute follicular tonsillitis appeared following the operation. I would hesitate very much before trying the operation again under cocain. Since the publication of Dr. Freer's paper I used his method in two cases. I was able to complete it with only a slight faintness on the part of the patient, and there seems to be no more pain than in any operation for the removal of a septal ridge. In one of these cases where there was a deflection of the bony septum, instead of chiseling above and below as described by the author, I used the Hajek chisel, removing the apex of the ridge.

In regard to perforations following operations for deflected septum, I should like to hear from some one who has seen bad results from these. In response to a question on this point to Prof. Moritz Schmidt of Frankfort, he said he had never seen bad results from such perforations, and that in some cases he would feel no regret from having them follow. It would seem that where the deviation is not perfectly corrected a perforation might be a conservative factor.

DR. EDWIN PYNCHON, Chicago—In his discussion, Dr. Freer said he ofter found simple deflections, but my experience has been the opposite. There is, in my experience, almost always more or less thickening. The occasional unfavorable results from the Asch operation may, I think, be due to such thickening. It is advisable to first reduce the thickened deflection to a simple deflection. After doing the Asch operation, which I have done on several occasions, I find it necessary to do one or more minor intranasal operations in order to destroy the little ridges produced as the result of the Asch operation. I have not done this operation under cocain, but I shall do so. An occasional perforation will follow the Asch operation, but it in no way differs from perforations found at other times and from other causes. A small perforation here is not a source of annoyance if the septum is perfectly plain about it. The reason a perforation produces irritation is because there is a thickening of the septum posterior or superior to it. I have sometimes removed the thickenings in such cases and found the perforation caused no further trouble.

DR. G. HUDSON MAKUEN, Philadelphia—After reading Dr. Freer's original paper I resected the greater portion of a cartilaginous septum that was dislocated and protruded from the vestibule of the nostril for about half an inch. Not having all the instruments Dr. Freer describes in his paper, and perhaps owing to less skilful manipulation, I made a perforation at the junction of the skin with the mucous membrane fully half an inch long. I was surprised when I found it there, but it closed up fully by first intention, and I doubt if anybody, by looking into that nose, would know that any operation had been done.

DR. KATE W. BALDWIN, Philadelphia—One word in regard to local anesthesia in the Asch operation. Cocain, menthol and carbolic acid, equal parts, as an anesthetic enable one to do the Asch operation entirely satisfactorily without general anesthesia. This combination is a very strong local anesthetic and must be used more sparingly than cocain alone.

DR. EMIL MAYER, New York City—Dr. Farrell's point is well taken, and I shall omit all personal reference to Dr. Asch in the paper before publication. I felt that I owed an apology to the section for again presenting my views on this subject.

Regarding Dr. Freer's methods, I would like to say that dissections have been done ever since any operations were attempted on the nose. I must take issue with the statement that deviations of the cartilaginous septum are practically always associated with bony deviations. In the specimen which I here present and which I have just taken from Dr. Cryer's exhibit before you, you will see deviations of the cartilage with perfectly straight bone.

Dr. McAuliffe has called attention to the need of some slight operation being required after the deviation has been relieved. This does occur and is simply due to the anatomic conditions present. It is a mistake to believe that the septum is all of one thickness. It is broadest at its junction with the maxilla and, hence, after operation, we have a thickened base to relieve. This is done as though we had an ordinary enchondrosis to deal with.

Dr. Freer, in his original paper, said that he used Roe's crushing forceps and, hence, I made the comparison between the exquisite pain of that method and that of the Asch forceps. I protested against the statement that we work in the dark. The final outcome of all discussions on this subject will be that such operation will be chosen as best suits the individual case and with such methods and results with which the operator is most familiar.

A Preservative Solution.—J. A. Shellenberger of Philadelphia says in the *Philadelphia Medical Journal* concerning the best solution for keeping pathologic specimens: Some years ago I preserved a goodly number of specimens very satisfactorily in the following solution:

℞.	Chlorid of sodium	ʒiv	120
	Pulv. alum	ʒv	150
	Hydrarg. bichlorid	gr. ii	12
	Aq. Pur.	Oii	960

M.—In very delicate preparations use double the amount of water.

RECURRING MULTIPLE ANGIOMATA OF THE SEPTUM.*

JOHN O. McREYNOLDS, M.S., M.D.
DALLAS, TEXAS.

It is not my purpose at this time to present an exhaustive study of the literature of this affection, but only to report an interesting case which is now under my care, together with the treatment I have employed and the comparative failures that have followed, in the hope that the wider experience of the members present may aid me in the more successful management of an exceedingly obstinate trouble.

The patient, Mr. L. L. K., a young Jewish merchant of Dallas, is 32 years of age; and aside from his nasal disease is in perfect health, and gives no history of any serious illness or constitutional infection that would have any bearing on the subject. He reports that his mother for many years was subject to repeated very severe attacks of nasal hemorrhage that resisted all efforts at relief by very competent physicians. She finally died of some unrelated intercurrent affection.

Our patient is about six feet tall, weighs about 160 pounds and is rather pale in appearance. The general conformation of the nose is that which we so frequently observe among the Hebrews, but the type is not exaggerated and the contour would be considered normal. His habits as regards tobacco and alcohol are exceptionally good, and he is not addicted to any form of dissipation to my knowledge.

The interior of the nose, on inspection, reveals a fairly normal state of the turbinated tissues, and the structures about the nasopharynx are in good condition. But on each side of the cartilaginous septum, when the nose has not been recently subjected to any form of treatment, are a few very dark blue elevations, each about the size of a pea. They are discrete, rounded in shape, and are most numerous in the anterior superior portion of the septum. They are composed almost entirely of blood vessels apparently of the venous type and they do not resemble in color, contour or behavior the granulation tissue which we see following operations on the septum. In fact, they are little blood tumors, and on the very slightest provocation and many times without any discoverable reason, they will break forth without warning, and for an hour or more will bleed furiously, until the loss of blood is at times very great.

So far, we have not been able to find any marked alteration in the character of the blood itself and there is nothing like a general hemorrhagic tendency. Wounds in other parts of the body proceed in the normal way, and in other parts of the nasal cavity there has never developed any disposition toward hemorrhage. After a period of bleeding these little tumors are somewhat collapsed, but they soon fill up again, and by the following day they are again ready to repeat the process. Generally the bleeding is unilateral, but sometimes it is bilateral, and it occurs most frequently when bending forward or under the conditions which would exaggerate any ordinary epistaxis.

With regard to the treatment we have employed, looking to any possible constitutional background, we have administered a long line of alteratives, tonics and astringents in succession, and at different times, but without any appreciable results. For the local condition we have used all the most important chemical astringents and caustics in modified form, and with some degree of success. But by far the most useful agent that we have so far employed was the electrocautery for the complete destruction of the tumors and their tributary blood vessels immediately around them. This will effectually prevent the hemorrhage for a few weeks, when the patient again presents himself with another series of tumors demanding obliteration. More recently I have been using electrolysis in the region of recurrence, hoping that in this way I may be

able to hold permanently the ground which I can always temporarily secure by the employment of the electrocautery.

Now, gentlemen of the Section, if you have any ideas to advance that will contribute to the permanent relief of this affection I wish to assure you that your suggestions will be most gratefully received, and due credit will be entered to your account in the future management of the case.

MERCURY IN SYPHILIS:

ITS ADMINISTRATION HYPODERMICALLY IN CONTRAST WITH OTHER METHODS.*

EUGENE FULLER, M.D.
NEW YORK CITY.

The question of the part played by mercury in the management and cure of syphilis is outside the sphere of the present paper. In fact, that question has long ceased to be a burning one, the potency and efficacy of mercury in this connection being admitted by all sane, honest and educated opinion. The relative value in the treatment of this disease of mercury and the iodids and the scope of each, although subjects of importance, will also not be here discussed.

The object of this communication is a consideration of the therapeutic methods of administering mercury, the rules to be observed in the employment of these methods, the relative advantages of each and the great importance of their proper adaption to individual cases.

ACCESSORY TREATMENT.

As a prelude to this discussion, however, the importance on the part of the patient of the observance of certain general rules tending to make the system tolerant of mercury, no matter how administered, should be duly emphasized. The most important of all these is the existence of a normal and cleanly condition of the teeth and gums. Decayed teeth should be filled or extracted, tartar removed and any defects at the line of junction of the gums with the teeth remedied. Careful brushing of the teeth and the use, twice daily, of a peroxid of hydrogen mouth wash is in all cases most essential. Oftentimes it is impossible for a person who maintains the mouth in a foul condition to tolerate mercury in sufficient quantity to stay the progress of syphilis. The avoidance of alcohol, the ingestion of an abundance of nutritious food, the observance of hygienic conditions and the regulated practice of physical exercise are other general rules, the following of which should be insisted on.

THE METHODS OF GIVING MERCURY.

There are three general and usual methods for the therapeutic administration of mercury, namely, by the mouth, cutaneously and hypodermically.

Administration by the mouth is the common method, and if judiciously so given the drug satisfactorily accomplishes its purpose in the majority of instances. There are many forms in which mercury by the mouth is administered. The metal in its natural state as pill-mass or as gray powder can be prescribed or one of the various salts of mercury can be given. Metal mercury salivates rather more readily than do the salts. If a person is naturally prone to looseness of the bowels, pill-mass, for instance, would be of little use, as its administration, even in small doses, would be apt to so accelerate the bowels that little or none of it would be absorbed. In a subject of naturally bilious or constipated habit the drug so given may be of special value, since, besides producing its constitutional effect, it also corrects the function of the bowels. Among the salts of mercury the bichlorid, the biniodid and the protoiodid are perhaps the most frequently prescribed. The bichlorid has comparatively little effect, as a rule, on the bowels. To be tolerated by the stomach it should be taken when that organ is full, and it should also be swallowed in conjunction with a rather long drink of water. Bichlorid of mercury to the amount of ⅛ grain three time a day can, in many instances, be well tolerated. In most cases the initial dose of the drug should be 1/20 to 1/16 of a grain, from which starting point the size of the dose should be increased. Some stomachs will not tolerate this salt. Where this form of mercury is pushed beyond the toleration point and where the stomach does not rebel a mercurial tremor is apt to be observed. Many of the preceding remarks apply to the biniodid, although I am not inclined to give that salt in quite as large doses as the bichlorid. The protoiodid is a salt much used and variously commented on. In the experience of many it is found too irritating to the bowels to be tolerated in a sufficient amount to overcome or even stay the progress of syphilis, provided the disease shows any evidence of activity. In my experience most brands of protoiodid made in this country are too irritating to be of value, small doses producing colicky pains and loose bowels. French imported protoiodid is much milder, and of this many times a patient will be found capable of tolerating ½, ¾, or even 5/6 of a grain three times a day before the bowel symptoms develop. Protoiodid is a safe form of the drug, as it shows little tendency to salivate, the explosive bowel symptoms being the usual evidence that the dose limit has been reached. With this salt, as with the bichlorid, the initial dose should be small, the maximum one being reached by a gradual progression. Little of a descriptive nature need be said regarding mercurial inunctions and fumigations. When more mercury than the system can tolerate is by these methods absorbed, mouth symptoms, chiefly in connection with the teeth and salivation, manifest themselves. Therapeutically the cutaneous methods are, as a rule, efficacious. The chief arguments against them perhaps lie in the time they consume and the discomfort and uncleanliness they occasion, together with the publicity which may be not only associated with their administration at special establishments, or by attendants, but also caused by the continual soiling of the body and underclothing.

THE HYPODERMIC TECHNIC.

As the administration of mercury hypodermically is of somewhat recent origin, and as its therapeutic use in this manner is still restricted to the practice of comparatively few surgeons, it may be well to devote some special remarks to the technic of this form of treatment. In the first place, mercury so used can be administered as an aqueous solution of a salt or as an insoluble salt suspended in an oily medium. The medication should not be injected subcutaneously, but intramuscularly and deeply in connection with thick fleshy structures. The gluteal region represents the part best suited for these injections, care being taken not to involve an area so low that the sitting posture subjects it to direct pressure. If a soluble salt of mercury is to be employed the corrosive chlorid is to be preferred dissolved in a normal aqueous salt solution, each 10 to 15 m. of the solution containing ¼ grain of the mercurial salt. The presence

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

of the corrosive sublimate insures the sterility of the solution. As much as ¼ grain of the corrosive sublimate can be injected daily or ½ grain every two to three days. In commencing treatment, however, it is not well to make the initial doses as large as these until the tolerance of the individual to the drug is established.

Calomel suspended in sterilized olive oil is the form in which the insoluble mercurial salt was injected in the early experimental days of the treatment. Although the systemic mercurial effects from such injections were marked, still they were very unsatisfactory, owing to the painful local after-effects produced, many patients being rendered so sore in the gluteal region as to be in a large degree crippled for a week or so, while in a few instances actual abscess formation resulted. These disagreeable effects resulted chiefly from two causes: the difficulty in keeping a vegetable oil in a sterile condition and, to a less degree, to the natural irritating quality of the calomel. The substitution of liquid petroleum products in the place of olive oil worked a great change for the better in this method of treatment. Liquid vaselin, albolene and benzoinol are some of the names given to these petroleum derivatives. At the present time calomel is by many still employed suspended in one of these latter preparations, and the results reported from it when so used are satisfactory. Another mercurial salt, insoluble in oil, which has to a considerable degree supplanted calomel in this connection, is the salicylate of mercury. The salicylate is a powder which closely resembles the mild chlorid in gross appearance. The therapeutic strength of the two when employed in this manner is also identical. The salicylate is supposed to be the less irritating. As the result of much personal experience I have adopted it as the form of mercury I generally employ when using the drug hypodermically.

The ordinary full dose of the insoluble salt so injected is 1½ grains. This amount can be given in 20 minims of the oil. Twenty-four grains of the salt in ℥i of the oil would make a mixture every 30 minims, of which, when well shaken, would contain 1½ grains of the salt. The syringe to be used should be one of ℥i capacity, with a needle about 1¼ inches in length and of the bore and thickness of a small-sized aspirating needle. The caliber of an ordinary hypodermic needle is too fine to transmit oil. Syringes which are made wholly of glass or all of glass, with the exception of asbestos packing to the piston, are to be preferred. The oily mixture should be warm, about the temperature of the body when injected. Antiseptic precautions should, of course, be observed and the syringe and the solution should be sterile. The patient should stand erect with the buttocks exposed. After the mixture has been thoroughly shaken the syringe should be quickly filled, the needle attached and the injection given. Everything in this connection should be done speedily except the actual injection, which last should be gradual, a minute or so being taken to slowly inject the dose. The patient should be instructed to relax his muscle while receiving the injection. If 30 minims are to be injected care should be taken to load the syringe to the extent of 40 to 45 minims, and while the injection is being given the outer end of the syringe should be tilted slightly upward. The reason for this lies in the fact that in a freshly shaken oily mixture there must, of course, be an admixture of some air bubbles. If the directions here laid down are followed all these air bubbles will collect during the process of injecting in the upper further portion of the piston and be contained in the last 10 or 15 minims which are not injected. If at any time during the process of injecting much resistance is met to a further depression of the piston, or if the caliber of the needle becomes plugged by a packing therein of the mercurial salt, the needle should be immediately withdrawn and the remainder of the injection given in another place.

PRECAUTIONS.

Little pain or discomfort should be occasioned by the administration of this treatment. Sometimes the needle strikes a somewhat sensitive spot. The only really disagreeable feature connected with the treatment lies in the occasional puncture of a blood vessel of some size. This may cause a little intramuscular hemorrhage, the result being the leaving of a sore spot, which may persist for several days pending the absorption of the clot, or the end of the needle being left piercing the caliber of a vessel while the injection is being given the oil is taken immediately to the lung, the result being an embolism, which is evidenced by spasmodic coughing and some temporary dyspnea. It is on this last account that stress is laid on the slowness in the administration of the injection, so that if any chest symptoms develop the needle can be withdrawn. If severe chest symptoms develop the patient should lie down till they disappear. In 15 minutes to half an hour such symptoms generally disappear. In very rare instances a patient may have a reminder in connection with his chest for several days after such a mishap.

An injection of this description and dose is sufficient to medicate the average individual for five days to a week. The first few injections, and especially the very first one, are apt to produce systemic effects much more vigorously than are subsequent ones. In other words, individuals, as a rule, become systemically accustomed to mercury so given, the result being that they tolerate these injections without experiencing any special immediate or following discomfort. It is not unusual after the first injection for a brisk diarrhea to develop in an hour or two and last the better part of a day. Indefinite muscular pains or nervous symptoms somewhat akin to hysteria may with others be the immediate and temporary after-effects, while with many soreness of the teeth are experienced. On this account I make it a practice to explain to a patient preparatory to the administration of the first injection that some prompt systemic symptoms may be felt.

Although 30 minims of the oil mixture represent the average dose, many individuals will be found to take 40 minims without developing any systemic intolerance, while with a few 20 minims will be found to represent the dose best adapted. This form of injection, it is seen, does not require so frequent repetition to produce a given effect as does the corrosive sublimate solution.

Judgment must be used in hypodermic medication not to produce salivation. The gums must be watched and the breath observed. If mercurial odor be evident in the breath or if the gums be characteristically tumefied and bleed on pressure a repetition of the treatment must not be given till these symptoms subside. Although care should always be exercised in the continuous administration of mercury by any method, lest undue effects from the drug arise, especial care should be observed in connection with the hypodermic administration. I do not wish, however, by this remark, to frighten anyone so that he will be afraid to use this treatment, for I am firmly of the opinion that at the present time far more harm results in connection with

syphilis from the administration of too little than of too much mercury.

CHOICE OF CASES.

If an individual presents himself during the primary stage of syphilis and keeps under observation so that mercurial treatment can be inaugurated as soon as a definite diagnosis can be made, then, in most instances, the administration of the drug by the mouth is the form of medication to be first tried. If the drug so administered is satisfactorily tolerated and succeeds in not only dissipating the symptoms which may be present, but also in preventing the development of new ones, then there is no good reason for displacing the method first adopted in favor of another. Not infrequently in such an instance, however, mercury by mouth, although well tolerated, may not, especially during the first few months of its administration, be potent enough to entirely hold the disease in abeyance. In such cases a hypodermic injection given from time to time will satisfactorily supplement the effect of the mercury taken by mouth. If a person presents himself for the first time late in the secondary stage of the disease, where, owing to anemia, facial or other prominent eruptive manifestations, alopecia, cephalalgia, rheumatoid pains, mucous patches or like developments, it may be of the greatest importance to quickly quell symptoms, not only for the good of the individual, but also to prevent the fact that syphilis has been contracted from becoming generally known; then hypodermic medication is to be recommended owing to the quickness of the ensuing results, a marked fading in connection with an eruptive lesion and decided cessation in connection with pain being noted even after the first injection. In a case such as this after the disease is well under control, then it may be that another form of medication can be substituted.

ILLUSTRATIVE CASES.

There are a certain class of cases wherein mercury by mouth has little or no effect on syphilis. In a majority of this class the drug is not absorbed from the alimentary canal. This non-absorption many times is accompanied by diarrhea, though occasionally the bowel action seems normal. In the minority of these peculiar cases mercury taken by mouth is absorbed perhaps to the extent of producing soreness of the teeth and gums or salivation and yet may exhibit little potency in staying the progress of syphilis. In all these cases mercury should be administered cutaneously or hypodermically in order to attain satisfactory results. As there are some claiming to be authorities on syphilis who still declare that mercury administered by mouth is capable of successfully combating the disease in all instances, it may be well to make special allusion to the two following cases taken from my practice:

One was that of a man who first came to me nine months after his chancre. He had been put on mercury by mouth as soon as his chancre had fully developed, and had continuously so taken the drug until he left his first adviser and came to me. His alimentary tract had apparently tolerated the drug and he had been able to take it in full doses. So hard and persistently had the administration of the mercury been pushed that the gums and teeth had many times been resultingly affected. Three months after the chancre characteristic headaches began to appear, and then gradually the spinal nerves became involved. For six weeks before consulting me vertigo, more and more marked, had been associated with the headaches, the severity of which had become intense. The spinal condition had become so marked that the patient walked with great difficulty—and then with a bent and rigid posture. Areas of great sensitiveness had also developed over the cranium. As soon as the patient came under my care all mercury by the mouth was discontinued and the drug crowded hypodermically. A prompt amelioration of symptoms resulted and in six weeks he was in a comfortable state. Business at that time calling him away, the previous symptoms promptly returned, in spite of mercury by mouth. These were again subdued by hypodermic injections as in the first instance. This case finally got well under a prolonged course of hypodermic medication.

Another case which I will cite was that of a man who first reported with an initial lesion. After watching him long enough to make a diagnosis of syphilis positive the attempt was made to administer mercury by the mouth. The form of drug first used was pill-mass, gr. ½, three times a day being ordered. In four or five days marked salivation began in spite of careful attention to the mouth. After a wait of 10 days another attempt was made, gr. 1/16 hydrarg. chlorid corros., twice a day, being prescribed. In a few days the mouth again became sore, and the drug had to be stopped. In the meantime marked secondary evidences of the disease were rapidly developing. A careful trial was next made of inunctions. These were well tolerated. The disease, however, was precocious in its development, and on that account I thought well of making a trial of hypodermic treatment. The first hypodermic was very light, through fear of resulting mouth symptoms. As these did not develop, the hypodermic dose was quickly augmented and a full, vigorous course of such treatment was given. No mouth symptoms due to mercury manifested themselves during this latter treatment, and the subsidence of the syphilitic evidences was satisfactory and progressive.

In concluding, I wish to champion the cause of mercury hypodermically in conjunction with large doses of an iodid by the mouth in the treatment of syphilitic ataxia in such of those cases as come under observation before the spinal lesion has so resolved itself into sclerous tissue as to be wholly beyond the influence of antisyphilitic medication.

252 Lexington Avenue.

DISCUSSION.

Dr. A. W. Baer, Chicago—The question of the comparative value of the organic and inorganic mercurial compounds in the treatment of syphilis seems to be still unsettled. I have had very little to do with the organic salts, as I have found the inorganic salts efficient and reliable. I have no experience to report on the hypodermic administration. I prefer giving mercurials by the mouth and inunction and have not seen any reason to abandon this method as I have found it entirely satisfactory.

Dr. W. J. Robinson, New York—Has the author of the paper had any experience with mercuric succinimid. From some observations made I have been much impressed by its freedom from irritating quality. It can be combined for hypodermic use with cocain if desired. In Germany this salt is used in 5 per cent. solution, with which is combined 1 per cent. of cocain hydrochlorate.

Dr. Eugene Fuller, New York—I have had no experience with the succinimid. No doubt there are many cases where giving the mercury by the mouth will answer the purpose quite as well, but it takes too long for the mercury to produce its constitutional effects, when given by the mouth, to make it suitable for use in urgent cases. In such cases, the hypodermic method is preferable on account of its prompt action and accuracy of dosage, and the fact that it is administered by the physician. There are many cases which can not be kept under observation for the length of time required for successful treatment, when they are allowed to take the medicine themselves.

Health in Islands.—It has been frequently observed that the inhabitants of islands and small peninsulas attain longer life than those of continents. The Barbadoes, Greece, Madeira and the Shetlands are quoted as illustrations of the truth of this statement.—*Medical News.*

DOSAGE OF LIQUID MEDICINES: A SIMPLE PLAN FOR GREATER ACCURACY AND METRIC MEASURES.*

CARL S. N. HALLBERG, Ph.G.

Member Committee of Revision, U. S. Pharmacopeia; Professor of Pharmacy in the School of Pharmacy, University of Illinois.

CHICAGO.

The strongest reason for the adoption of the metric weights and measures is the use of the present collection of arbitrary standards, conceived by chance and inherited by ages of medieval crudescence.

The paramount quality of that by which quantities are determined must be accuracy; that by which comparison is made must be as nearly invariable and inflexible as can possibly be devised, otherwise it is not a true standard. Scientific accuracy requires also that a fixed relation, only varied through variation in temperature, should prevail between weight and volume, and consequently that units of weights and liquid measures must be correlated, that is commensurate. No scheme for comparison which does not meet these fundamental requirements is worthy the name of a system, nor should be tolerated in this twentieth century.

CUSTOMARY MEASURES.

Subjecting the customary weights and liquid measures to this test they are found to be so absolutely at variance as to be a travesty on our boasted civilization and progress. Take the ounces of the three alleged systems for comparison, and they show the following equivalents in grains: avoirdupois, 437½ grs.; apothecaries', or troy, 480 grs.; fluidounce, 456 grs. (water at 15 C.). This is due to the fact that one pint of water weighs 7,300 grs. (approx.) instead of one avoirdupois pound, or 7,000 grs. In other words, the old saying "A pint's a pound, the world around," is as far from the truth as probably was the conception of the world by those who coined the catchy phrase.

There is a difference of about 4 per cent. which appears also in the apothecaries' ounce as against the fluid ounce, and is thus introduced in the smaller denominations, drams, grains, and minims; the fluid dram being equivalent to 56 grains, the minim about 96/100 of a grain.

INACCURATE DOSAGE.

It is this very discrepancy or lack of commensurability which is so trying both to the physician and pharmacist. In the formulation of percentage solutions, where great accuracy is usually required, there will be a discrepancy of from 4 to 10 per cent., according to which particular method the quantities have been determined. If, for example, the formula appears:

℞. Atropinæ sulphatis ..... gr. x
Aquæ sterilatæ ad ..... ℥i
M. Et. f. sol. Sig.: Use one minim.

If prepared by fluid measure each minim will represent 1/48 grain of atropin sulphate; if, on the other hand, a troy ounce of water should be used, owing to the absence of the prefix "fl" before the ounce symbol, then the amount of atropin in one minim would be about 1/50 grain, or, if perchance avoirdupois ounce be used, 1/44 grain would be contained in one minim. The difference in dosage may not be serious, but should such variations be tolerated, or such inaccurate methods be continued?

Aside from the disadvantages of inaccuracy and lack of uniformity of the customary weights and measures, there is also the lack of correlation with our decimal system of notation. For domestic purposes the convenience of a decimal system of weights and measures, in harmony with our decimal system of coinage, must be equally as great as this so-called international system now appears to be advantageous for the extension of foreign trade. As is well known, the decimal system of weights and measures is now in use in all but English-speaking countries. As it is complementary to our decimal system of money, it should have been adopted along with it, as advocated by Jefferson and John Quincy Adams. The return to the old system of pounds, shillings, and pence would be no more absurd than to continue to inflict on the coming generation the present aggregation of weights and measures.

THE FALLACY OF THE SPOONFUL.

Contemporaneous with the customary weights and measures are the so-called domestic measures for liquids, as represented by the "spoonful." How this useful utensil varies in capacity is well known, and when it is also remembered that the amount of liquid a spoon will hold when "full" depends on the generosity of the person filling it, the spoonful method of administration, while innocuous for placebos, can not be regarded as scientific medication. The "meniscus," or the level of a liquid, which determines a measured quantity, is, according to the best authority (Dr. Hager), the medial of a transverse line drawn through the lowest point in the surface of the liquid and one drawn at the highest point of contact with the liquid and the confining sides. This line may be easily determined when the liquid is measured in glass, and the smaller the diameter the more exact the measurement. As is well-known, the graduated pipettes and burettes used in chemical work are constructed on this principle. In measuring by a spoon the *meniscus* can not be readily determined, and owing to the cohesion of liquids, especially when aqueous, after the spoon has been filled to its apparent level, an equal amount of the liquid can be poured on top of it, if done slowly, without any of the liquid running over. For these reasons it may be safely asserted that instead of a teaspoonful being equivalent to one fluidram, it may be two fluidrams. In larger spoons the difference is proportionately less, but yet so great as to have no semblance of accurate measurements. Not only should standard spoons be devised, but a uniform meniscus should, if possible, be adopted, although the spoon measure, as best being empiric, should be superseded by graduated glass measures, similar to those at present extensively used. A readjustment of the relative volumes of the three different spoon measures in vogue is necessary, and such relation should correspond with metric measures.

Recently the following metric equivalents have been approved by the Philadelphia College of Pharmacy, and incorporated in the scheme presented further on in this paper: One teaspoonful = 5 c.c.; one dessertspoonful = 10 c.c.; one tablespoonful = 15 c.c.

The following definition for the meniscus, originally taken from the French Codex, has also been approved: "A spoon is full when the liquid it contains comes up to, but does not show a curve above the upper edge or rim of the bowl."

THE DROP.

But if the spoonful measure is only an approximation, the drop shows still less uniformity in volume. As

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

is well known, the size of drops varies with different liquids, is influenced by the size of the container and shape of the lip from which it is dropped, and by the temperature and volatility of the liquid. No careful physician would administer a potent agent by drops except through a minim pipette. Recent investigations have shown that drops of uniform size may be obtained by dropping from a pipette of a certain outside diameter; thus a tube of 3 mm. outer diameter will deliver 20 drops of water at 15 C., which will measure 1 c.c. when dropped at the rate of one drop per second. Nor is the size greatly influenced by the character of the liquid, be it watery or more mobile. Such standard "droppers" have been recommended for the exact measurement of medicinal liquids and, owing to its many advantages, this drop has been incorporated in the table.

ADVANTAGES OF DECIMAL DIVISION.

The decimal system has advantages in computing dosage and formulating combinations not possessed by the binary or octonary system on which our customary weights are based, because in accord with our system of numeration.

But it is in preparations for external use that the decimal system is *sui generis,* because their strengths are usually referred to by the per cent. or by per mille. Thus solutions for injections, etc., may be quickly prepared by taking for 100 c.c. the number of grams represented by the percentage strength; for 10 c.c. decigram may be used. Ointments, plasters, etc., may be equally readily computed.

EXACT EQUIVALENTS THE OBSTACLE.

The greatest obstacle to the more general acceptance of the metric system, especially for the older practitioners, has been the attempt to learn and to use exact equivalents for the customary weights and measures. Since the latter are not in accord with each other, the discrepancies appear in the respective metric equivalents, and the result is chaos and confusion. To illustrate: While 32 grams is a fair approximation to the apoth. ounce, it will not do to take it as equivalent to the fluid ounce, because in that event 16 fluid ounces would be equal to 512 gram, or one pint, considerable more than one-half liter, which at once makes the error apparent. This same discrepancy occurs in the other

ADAPTATION OF APOTHECARIES' WEIGHTS AND MEASURES TO THE METRIC SYSTEM.*

This adaptation is based upon the fact that 20 drops of water at 15° C., delivered from a minim pipette with an external diameter of 3 mm., will measure one cc.

* From a scheme of adaptation presented to the Committee of Revision of the U. S. Pharmacopeia (1900) by the author.

A little practice will soon prove that by formulating the quantity in decimal amounts, the individual dosage may be seen at once without, as a rule, entailing any calculations. If, for example, ten or its multiple of powders, pills, etc., are ordered, the amount of the active agent for the whole quantity is at once apparent; thus:

	Dose.	10 powders.	20 powders.
℞. Resinæ podophyllini	0|01	0|1	0|2
Hydrargyri chloridi mite . .	0|1	1|0	2|0
Sacchari lacti	0|5	5|0	10|0
		10 pills.	30 pills.
℞. Acidi arsenosi	0|005	0|05	0|15
Strychninæ	0|001	0|01	0|03
Quininæ sulphatis	0|1	1|0	3|0

If a liquid mixture is desired, it should be similarly ordered in quantities of 100 c.c., 50 c.c. or 25 c.c.

	Dose in 5 c.c.	Dose in 100 c.c.	Dose in 50 c.c.
℞. Morphinæ sulphatis	0|01	0|2	0|1
Potassii bromidi	0|5	10|0	5|0
Chloralis	0|3	6|0	3|0
Syrupi aurantii ad	5|0	100|0	50|0

denominations: dram, grain, and minim, and is too serious an objection to be disregarded.

There is only one way of using the metric system, and that is to use it, or a decimal adaptation of it, combining the desirable units, grain and minim, which are so inseparably bound up with dosage in the medical mind.

With 20 drops, equivalent to a cubic centimeter, instead of 16 drops, and assuming the gram to contain 20 grains instead of 15.432 grains, we obtain at once these two essential denominational units as concordant and with the necessary decimal relation to the metric units, cubic centimeter and gram, on which a simple adaptation of the customary weights and measures may easily be constructed, as shown by the accompanying table.

As will be observed, there are no changes whatever in the metric standards.

The new metric grain proposed is about one-fifth less than the troy grain.

The minim is a little less than one-fifth smaller.

The new dram is about two-ninths greater than the apothecaries'.

The new fluidram is about three-elevenths larger than the present fluidram.

Both drams contain 100 grains or minims.

The new ounces would be all alike, representing 25 gm. or c.c. and would be from one-eighth to one-fifth less than the customary ounces.

The metric ounce, 25.0; one-fifth less than 1 apoth. ounce, 31.0; one-sixth less than 1 av. ounce, 28.35.

The metric fl. ounce, 25 c.c.; two-thirteenths less than 1 fl. ounce, 29.5.

The metric pint and pound are 5 to 10 per cent. greater respectively than the pint and avoirdupois pound.

The discrepancy in these two is not great, and would be readily adjusted. Each would contain 20 ounces, or 100 drams, or 10,000 grains, or minims.

The advantages of this adaptation for the calculation of doses, the strength of preparations, etc., is self-evident. The dose of an active agent in any quantity of a solution or mixture would have a definite decimal proportion and could be quickly calculated in metric grains, or minims. The smaller quantities represented by the proposed grain and minim would not be as objectionable as is the lack of proper relation between the present denominations—a fruitful source of error in practice. Besides, the difference is on the safe side, and by employing the proper designations no mistakes could occur. The author recommends that the abbreviation of "Gm." for gram should always be written with a capital G, to avoid confusion with "gr." for grain, which is never written with a capital letter. The metric fluidram is especially designated "metric spoonful" to afford an accurate method for administration of liquid medicines.

The adoption of a definite spoonful measure would cause the domestic measurement of medicines by graduated measures exclusively. Of the centiliter, or tablespoonful, the same may be said. The decimal proportion of the ounces to the drams and also to the grain and minim would enable the prescriber to at once estimate the quantities and yet have the metric equivalents at a glance. The deciliter, or four-ounce, would be an exceedingly convenient quantity for extemporaneous prescription; containing 20 fl. drams it is well adapted to formulas of which the dose is a teaspoonful. For example: one grain at a dose; then 20 grains=1 Gm. to 100 c.c., or 4 fl. ozs.

In the belief that the adoption of some such adaptation, possibly as an appendix in the U. S. Pharmacopeia, would materially aid in the more general acceptance of the metric system for prescription writing, this scheme has been proposed to the Committee of Revision and is now presented to the profession.

NOTE.—*This paper was referred to a committee consisting of Drs. Frank Woodbury, H. C. Wood, Jr., and A. A. Eshner of Philadelphia to report on at the next annual session.*

A remarkable specimen was shown at the meeting of the "Section on Clinical Medicine and Surgery" of the Medical and Chirurgical Faculty, December 19, by Dr. José Hirsh. It was an immense aneurism of the arch of the aorta of 24 years' standing. The sac was entirely filled with a hard clot and had projected forward, evading the sternum at the junction of manubrium and gladiolus, so that these bones were at right angles to each other. Notwithstanding his condition, the man (a Frenchman) had led a laborious life as a bricklayer. The case was considered one of spontaneous cure. Owing to the position of the tumor, there was a remarkable lack of symptoms. Oozing of blood from the apex of the tumor took place from time to time, and infection occurred in this way, death being due to general streptococcus infection.

THE IDENTITY OF NERVE FORCE AND ELECTRICITY.*

J. EMMET O'BRIEN, M.D.
SCRANTON, PA.

There has been in recent years such advance by physiologists in knowledge of nerve mechanisms, though not of nerve force, and such advance by electricians in knowledge of electricity in its protean phases, that, I think, the view of the relation of nerve force to electricity ought to be taken up anew by physiologists and restudied in the light of modern electricity. Advances by physiologists appear in minutely studied anatomy of neurons, relaying nerve mechanisms, conduction paths, terminal mechanisms, etc., and advances in this direction by electricians have been in better knowledge of the electric phenomena of cables, learned since physiologic views of the electrical phenomena of nerves became rather arbitrarily fixed; of fine currents and the wide field of induction, as revealed by the telephone; new light on the merely relative value of insulation; the phenomena of high frequency currents and their apparent reversal of electric law in insulation; storage or secondary batteries; electric relays, repeaters, transformers, microphones, terminal mechanisms, etc., and lastly electrolysis and electrochemistry.

PRIORITY AS TO THIS THEORY.

Noting the analogies between nervous and electric mechanisms revealed by the advances of recent years in the separate fields of physiologic anatomy and electricity, I affirmed the identity of nerve force and electricity in a paper[1] entitled "Analogies Between Nervous and Electrical Mechanisms: What is Nerve Force?" to our county and state medical societies in 1900. On account of the importance of the subject, and because the same conclusion has since been reached through other paths by Professors Loeb and Mathews, I again present it, with some further studies. The lay press has, as you are no doubt aware, given entire credit for originality, not only in methods, but as to scope and conclusions, to Professors Loeb and Mathews. They are entitled to great credit for methods in arriving at the identity of nerve force and electricity.[2] But it is not the lay press but scientific societies and journals that ought to adjudicate the question of originality in method, scope and conclusions; and so to you I leave it.

THE SPEED OF NERVE IMPULSE TRANSMISSION.

In reviewing works on physiology I have not found reasons given for the usual statement that nerve force is not electricity. I presume that the supposed slow speed of nerve force, the apparent want of insulation, of continuous circuits and of galvanic elements in nerves have been the principal objections. If there are other, better reasons I am anxious to know and acknowledge their validity. It does not appear that any very decisive experiments indicating slow speed of nerve impulse have been made since those of Du Bois Reymond and Helmholtz, though theirs have been repeated by many. Although we have since learned much about electricity, these experiments appear to bind opinion still. These experiments were made and interpreted before much was known of the electric phenomena of cables; before

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. A. Stengel, Winfield S. Hall and Frank B. Wynn.

1. Published with drawings in the Pennsylvania Medical Journal, November, 1900.

2. See, for instance, "The Nature of the Nerve Impulse," by Mathews, Century Magazine, March, 1902.

the Gramme ring made electric power possible; before quadruplex telegraphy; before Reis invented the telephone or Bell perfected it; before Gray showed the harmonic duplex; or Edison perfected electric light, invented the phonograph or developed the miracle of the microphone discovered by Hughes in the variable resistance of carbon; before wireless telegraphy and the Roentgen ray; and before Tesla had revealed the apparent reversal of electric law of insulation by high-frequency currents. They were made before neuron anatomy was known. Charpentier, repeating the Reymond-Helmholtz experiments and ingeniously varying them, succeeded, according to the *Revue Scientifique,* in demonstrating about a year ago—that is, about a year after my first paper—that nerve force is electrical. While his conclusions favor the contention of my papers, I think that, with all other laboratory experiments so far made, they are not above criticism.

All these experimental data for and against the electric concept, are so far, I think, inadequate. You test a nerve cable at different points with depolarizable electrodes and, from the indications of a capillary electrometer, say that nerve impulse has a speed of only 30 meters per second. Does this test the normal physiologic currents of a nerve or warrant the conclusion as to speed? I think not. You apply the electrodes to the cut surface of a nerve cable, or of muscle, and get electric manifestations. You irritate a nerve and note the time of muscular contraction. Do any of these experiments directly measure normal currents or indicate their speed? I can not think so. The most that can justly be said for them is that they prove the presence of electricity in nerve and muscle. Suppose we applied precisely similar tests to a telephone cable or an ocean cable, we would get various electric indications and might call them cable impulses, negative variation, cathodic closing, cathodic block, etc., but would not be fairly measuring the speed of normal cable currents. I think it is safe to say that the speed of the normal current in nerves has never yet been measured unless we consider the first part of the double current observed by Charpentier to be such. The *Revue Scientifique* describes this phenomenon as follows: "A short electric excitation produces a double transmission on the part of the nerve. One part is transmitted almost instantaneously as in an ordinary conductor." In experiments on the speed of sensory impulses, as well as motor, the time of relay and terminal mechanisms will have to be estimated and deducted. The fact is, I believe, that the experiments relied on as determining the velocity of nerve current, while ingenious, are relatively coarse, clumsy and inadequate for the gossamer tenuity of the neurons and the fine electric currents they normally evolve and transmit. We need finer experiments than these, and on living nerves, to demonstrate the normal currents. Tesla, in 1900, announced an electric invention sensative to the contraction of a muscle merely in the same room with it. This may indicate the direction of hope for methods fine enough for the demonstrations that we need.

But there is other evidence: There is available a series of what we may call natural experiments involving speed of nerve impulse which have not been studied to their logic conclusion in that regard, although physiologists have taken note of them in regard to fatigue, etc. I refer to the cases of rapid muscle movement in man, animals, birds and insects. It seems to me that the wing vibrations of insects, running up into thousands per second, invite study and imply at a glance greater speed of nerve impulse than the conventional figure. The pianist's movements have been noted but are complicated. Scripture of Yale is the latest to make some tests of fatigue, not speed, in key tapping by non-experts. I have made a study of a more rapid movement than that of the pianist's, who uses ten fingers and many muscles. The expert telegrapher in speed contests uses the same flexors and extensors of the hand throughout. Having to move his key through the smallest possible space he attains a speed of 54 words per minute. This gives a well-attested average of 11¼ flexions and 11¼ extensions, or 22½ vibrations, of the hand per second, sending the mixed Morse characters of average press words. Some of these characters are dots, as the letters e, i, s, h, p, and the figure 6; 1, 2, 3, 4, 5 and 6 dots respectively. As the dot is shorter than the dash or the space, it is made by motions faster than the average of 22½ vibrations per second attained in sending the dots, dashes and spaces. Experts think twice as fast, or 45 vibrations of the hand per second. This means a rate of 22½ contractions of the flexors and 22½ contractions of the extensors per second for the dots, with an equal number of muscular relaxations. It does not seem probable that a nerve impulse is traveling down the line to the flexors while the extensors are contracting, or vice versa, so that it seems fair to divide the time between the two motions, leaving half a second for 22½ impulses and flexions and half a second for 22½ impulses and extensions. The length of nerve from brain to forearm may be about 30 inches. This means that not only does a normal nerve impulse travel 30 meters per second, but that over 30 impulses pass over the same meter of nerve per second, which is a different thing. Some physiologists admit the probability that each muscle contraction is maintained by a series of nerve impulses like those of the induced current used to experimentally tetanize a muscle. If that is true, and I am inclined to believe it, then our 30 impulses per meter, or rather 45 impulses per ¾ meter, per second, have to be largely multiplied. But if you reject the view of series-impulses and insist on a make and break current the time of muscle contraction will have to be deducted to leave the time of the nerve impulse which induced it. Muscle action is a visible, tangible, mechanical, time-consuming phenomenon. Where the time of a single nerve impulse and a single muscle contraction is to be divided how much shall we apportion to the mechanical action and how much to the flight of the nerve impulse which induces it? Until this is accurately determined I can only conceive the relative time to be the same as that occupied by the electric current traversing a conductor and that occupied by an armature, or a muscle, in responding to its call. But in any way that this problem can be figured it shows that normal nerve impulses travel faster than 30 meters per second. In this calculation I have not doubled the length of current path for a return circuit, but that possibility should not be lost sight of.

Normal nerve force is not only, as I believe, vastly faster than has been supposed, but electricity may be much slower in action than its well-known maximum velocity. There is a lag in cables due to capacity, inductive static charge and the electric reaction of armor. Nerves are cables although they appear to be often treated in experiments as if they were single uninsulated conductors. There is a perceptible lag in poorly insulated land lines in wet weather due to escape, short-circuiting, etc. So, in comparing electricity and nerve

force the minimum speed of electricity should be considered. It may be further reduced by adjustment of relays, repeaters, condensers, terminal mechanisms, etc. I have thus endeavored to show that there is no such gulf between the speed of electricity and nerve force as has been supposed. In both cases the velocity may be materially affected by conditions and mechanisms. It seems to me that further investigation and experiment in this direction by well-equipped physiologists will fairly meet the principal objection to the electric concept.

NERVE INSULATION.

The telephone threw a flood of light on induction and insulation. When, on the telephone line through which I first heard speech, I also read the Morse of neighboring telegraph lines I realized that induction occupies a wider zone than had been previously dreamed of. When telephone currents came through lines so poorly insulated or badly grounded that the telegraph would have been mute I realized that insulation is indeed merely relative, and what we now know of high-frequency currents has further enlarged this view. At one time it was supposed that nerve force could not be electric because the nerves were not insulated as in glass or gutta-percha. We now know that less insulation will suffice as for fine telephone currents.

NERVOUS AND ELECTRIC SYSTEM ANALOGIES.

The analogy between a single axone with its myelin sheath and an electric conductor with insulation is so obvious that I will not dwell on it, but will have something to say on insulation further on.

The analogy between a telegraph or telephone cable and a nerve cable armored with its sheath and containing numerous axones, each with its own myelin covering, is still more striking. The use of both is the same—communication, or the transmission of force.

Nerve and electric units will be compared farther on in this paper.

The analogy between nerve relays and electric relays is most significant; their purpose is the same, their mode of action is similar; there is variety of form in both, more apparent in electric relays because they are more familiar and more easily dissected.

Nothing can be more wondrously analogous than the multiple switchboards of the spinal cord and higher centers with those of the telegraph and telephone. Analogies may be traced in multitudinous terminal mechanisms of electric and nervous systems, and at both termini, that is, at sending and receiving ends of the circuits. We find analogy and, I believe, identity in the form of force energizing nervous and electric systems. We find, I believe, analogy in the speed of this force. We find more than analogy in the ensemble of force, velocity, conductors and mechanisms. We find identity of plan, purpose and use in nervous and electric mechanisms.

A galvanic cell no larger than a cartridge shell may work an ocean cable. The simplest concept of an electric unit is such a cell with a conducting circuit. Electric systems are built up of such units. The simplest concept of a nerve unit is a nerve cell: its dendrites, axones and collateral branches. The whole nervous system is built up of such units and these neurons evolve, transmit, repeat to each other and exchange through multiple switchboards the impulses necessary to the complex system of communication in the living body. The analogy between nervous and electric units is not merely in appearance, there is identity of purpose and use, namely, to generate and transmit force. In the electric unit the force is electric. In the neuron it gives electric manifestations as shown by the electrometer. Why is it not electricity? The gymnotus and some other fish produce and use electricity on the large scale as a defensive or offensive force; their electric cells are probably storage batteries. (Storage batteries do not retain or contain the electricity pumped into them; by it they are only placed in the chemical position to produce electricity. They would be better called secondary batteries.) If these fish produce electricity in organic cells and operate it through their nervous mechanism for purposes of warfare, it must be admitted that Nature can evolve electricity in organic cells and utilize it for peaceful purposes in the domestic economy of animals. She seems to have taken great care to provide a fine and complex mechanism for it. Nature's technic is not meaningless.

There have been cases of excessive production of electricity in human beings. Physiologists find in nerve cells two substances stainable respectively by acid and basic dyes; this indicates galvanic possibilities. Barker, in his great work, "The Nervous System," says that he rather favors Von Lennhosek's view, as follows:

> We can very well conceive of a variety of excitation, which, starting from the cell, perhaps even from the nucleus, streams constantly through the axone and in it in some way, perhaps by a process comparable to electrolysis, maintains the chemical conditions suitable for the assimilation of the nutritive juices.

If eminent physiologists can conceive this can we not conceive a fine current of electricity; not enough to work an Atlantic cable, nor needing a mammoth battery so vast as a gun-cap to produce it, but of sufficient e. m. f. to work a nerve cable a few thousand miles shorter and needing nerve cells proportionately small to generate it? True, the physiologists refer to trophic processes, but if we conceive such a current for nutritive purposes why not for the obvious and appropriate purpose of communication.

If we take an electric unit and place an electro magnet, chemical paper, any one of a hundred terminal mechanisms, say a muscle, in the circuit, the kind of work done will depend on the mechanism of the terminal. The same is true of the nerve unit and argues that the communicating force is the same. It will suit my rude notions of these analogies better and make my conception of them easier if you can admit the existence of complete, or return, circuits. Recent investigations show that not only are there probably two filaments sent to each terminal organ, but every axone has numerous collaterals. Groups of cells have intimate relations, and connections are, according to the neuron concept, contacted by variable resistances; besides these paths there are general return circuits possible, like in the telegraph and telephone. Endowed with motility the dendrites make contact by different paths for the nerve current through the nerve centers, thus doing automatically what the operator does at the telephone switchboard when she connects different subscribers. The analogy may seem even closer than this in the case of automatic telephone exchanges requiring no operator, but I do not mean now to suppose electromagnetism in the nerve repeaters, but rather that their elements react on each other like galvanic elements in a battery or, by induction, like condensers, transformers, etc. In alternating circuits the transformer repeats from one line to another and converts the current to a higher or lower voltage. Every induction coil is a repeater. The electric condenser relays, retards and intensifies discharge. The effect is varied if the plates approach or recede; doubtless the same is true of the nerve processes.

The question of insulation is important to the electric concept. There is probably no absolute insulation anywhere; it is relative; a matter of degree. Let me illustrate: A man was killed on a lamp pole by an alternating current of 2,800 volts. I traced the current from the wire through his spur, body, hands, to the metallic braces of the mast-arm, where it divided, part going down the pole and part through the metallic mast-arm and manipulating rod to a spike in the pole within ten feet of the ground, thence by the pole to the ground. On testing the escape through the pole by inserting an electric bell wire in it a few feet from the ground and grounding the other end of the bell circuit the escaping current rang the bell. In military telegraph experience during the Civil War I have not only worked successfully through badly insulated lines, but through some grounded intentionally for obstruction. A portion of the first Atlantic cable, used across Chesapeake Bay in 1862, furnished me varied experience in poor conduction, bad insulation and slow work. With the telephone when the old ground return was used I have heard speech when the line sometimes lay on the ground. With such a wire of twenty miles so badly insulated and grounded that speech became indistinguishable in the receiving diaphragm I have yet kept up communication by the simpler Morse signals through the more sensative telephone mechanisms. Communication has been had through a mile or more of water not insulated from the earth which formed the other side of the circuit; this by means of the Morse language and telephone instruments. Wireless telegraphy scorns insulation. Whatever theory others may have of it, mine is that there is a complete circuit, the earth forming one side of it, the atmosphere the other, and Marconi has worked it across the Atlantic without insulation. So, I say electric insulation is merely relative, the degree required depends on the kind of current, the purpose and the mechanisms used. If nerve force is not electricity, what other form of force is it that could be better kept insulated in the axones?

In considering insulation, relays and switching, I quote the following from Lombard in the American Text-book:

> The axis-cylinders of the many fibers which run side by side in the nerve trunk are separated from each other by the neurilemma and, in the case of the medullated nerves, by the myelin substance as well, so that there is not even contiguity, much less continuity of nerve substance. Thus the fibres of a nerve trunk, some afferent and others efferent, though running side by side, conduct independently of each other. For example, if the skin of the foot be pricked, the excitation of its sense organs is communicated to sensory nerve fibres, and is transmitted along them to the spinal cord, where the stimulus awakens certain groups of cells to activity; these cells in turn, by their branches, the motor nerve fibres, transmit the excitation down to the muscles of the legs, which . . . contract and withdraw the foot from the offending irritant. The sensory and motor nerves concerned in this reflex act run for a considerable part of their course in the same nerve trunk, but the sensory impulses have no direct effect on the motor nerve fibres, and the round-about course which has been described is the only way by which they can influence them. It is probable that isolated conduction by separate fibres and their branches holds good within the central nervous system as elsewhere, otherwise we could scarcely explain the localization of sensations or coördinated movements. It is possible that within the central nervous system the neuroglia may act to secure isolated conduction.

This is an admirable description. What is this system of conduction and isolation for? What force is it intended to convey? Can it be anything but electricity? There is said to be more than 50 per cent. cholesterin in the solids of gross nerve tissue; it is probably mostly in the myelin sheath; it is an insulating substance; the conductors are very small, 1/1200 of an inch in diameter and smaller; the current needed is very fine if a battery of percussion caps may work an ocean cable. Nature has taken such exquisite care to keep these myriad conductors separate as she weaves them in skeins and tracts and plexæ in their course through her multiple switchboards that I can conceive the force they carry to be none other than electricity. Please note the apposition of axones of opposite polarity, so well described by Lombard, and which is found quite general throughout the nervous system, and compare it with the ingenious method of transposition of wires by which electricians have successfully endeavored to neutralize induction in telephone cables and air lines. In this, as in many other things, they seem to have unconsciously imitated Nature, and I have no doubt that the decussation and transposition of conductors has, in part, the same intention and the same effect in both nervous and electric systems: namely, to neutralize induction.

The sympathetic system is peculiar as to insulation; its axones are generally unmedullated, but they have sheaths. Gotch & Horsley[3] found larger electric currents in non-medullated than in the medullated nerves, explained by Lombard by the fact that non-medullated nerves contain a greater number of axones than medullated nerves of the same size. The sympathetic system has a general function to perform: to maintain the tonicity of involuntary muscle and influence secretion. Compared with the cerebrospinal system I regard it as a storage, or secondary, battery and practically monofunctional. In that view it is unnecessary that its axones should be so perfectly insulated from each other as are those in the central system where the individual circuits have to convey special messages like private wires.

I trace analogy of mechanism and identity of function between tactile papillæ, Meissner's corpuscles, *tastzellen* and other nerve beginnings, and electric variable resistances, microphone transmitters and other sending mechanisms, some of which are almost as sensitive to the slightest compression as are the nerve organs. Electric conductivity, or its opposite, resistance, is varied enormously by the slightest pressure in the Blake, or long-distance transmitter, and the coil of nerve fiber in one of these nerve-sending mechanisms seems adapted to the same purpose and, indeed, fulfills it whether you admit that nerve force is electricity or not. The touch of a hair is appreciated by the microphone and by the nerve key; electric conductivity is varied in the microphone circuit sufficiently to affect an electro-magnet and translate the impressions into audible sound by the vibrating diaphragm; electric or nerve conductivity is varied in the touch corpuscle sufficiently to send a current through the nerve relays to the sensorium. I can not conceive any form of force that would respond to these mechanisms in either case but electricity.

Permit me to quote an occasional line of description from your latest text-books, especially from Barker's admirable work, and to flash a little electric light on it as we pass. Barker says: "A single neuron of one system is by virtue of a number of end ramifications able to enter into conduction relations with a number of neurones in the next higher system, . . . and per contra the terminals of a larger number of axones of one system may be arranged to influence only a small number of

3. Philosophical Transactions, 1891.

neurones of a neuron system of the next order." This in the light of electricity describes a multiple relay system of transformers through which not only signals are repeated, but force is diffused or concentrated. In other words, step-up or step-down transformers changing the e. m. f. of the current.

"Cutaneous sensory fields overlap" (Barker). That is, they are herringboned by nerve filaments reaching neighboring segments of the spinal cord, like two or three telephone systems in the same town and having the same subscribers, so that injury to one conductor will not prevent the subscriber, say a tactile push-button, from ringing up Central.

"Four qualities of sensation are mediated by the skin and apparently by specific sense organs, cold, warmth, touch and pain." (Barker.) This does not mean that the sensory nerves need differ from each other, nor from motor nerves except in polarity; nor that the force traversing them need be anything but electricity to convey these different impressions. The difference is in the terminal mechanism. The same sort of wire, the same electricity translates, conveys and reproduces musical tones, the composite vibrations of articulate speech, the Morse language, handwriting, print, pictures, light, heat, the *x*-ray, and so on, all depending on the terminal mechanism.

"A centripetal impulse, originating at the periphery, reaches the primary end station of the sensory neurones inside the central nervous system after passing through only one neurone." (Barker.) That is, it reaches the suburban exchange in the spinal cord, where the dendrites and cells that represent the Hello Girl automatically make the connections for local and long-distance communication.

"It was long thought that these peripheral end organs contained ganglion cells, but that view," says Barker, "has been proved to be false." This, to me, means that the battery is not in the touch organs of the skin, etc., but is in the individual neuron; in fact, in the local central, where it ought to be; and these end organs, whether tactile papillæ, platelets, free endings, Ruffini's or Pacini's corpuscles, end bulbs of Krause or others on the sensory side, are sending mechanisms; keys, push-buttons, variable resistance transmitters, etc., such as we find in telephones, cables, telegraphs, electric bells and the like; and they operate in the same way.

"The number of nerve fibrils in ordinary epithelial structures is enormous. It would appear that almost every epithelial cell stands in contact relation with one or more nerve fibrils, and perhaps this may be true of all epithelial cells." (Condensed from Barker.) This shows a distribution of conductors sufficient for the phenomena of sensation to be electrical.

Let us glance at a point or two on the motor side. "Each of the separate muscle fibers is supplied by at least one nerve fiber, and under normal conditions only acts when stimulated by the nerve." (The American Text-book.) On this point I said, in my paper to the Lackawanna County Society in May, 1900, that "The fact is, I believe, that every muscle unit is surrounded by an electric field of force, disturbance of which causes it to contract; and the same is probably true of every protoplasmic unit." Thus anticipating Professor Loeb's announcement on that point by nearly two years.

"The motor nerve fibers to the muscles terminate in end plates." These motor terminal organs I regard as nerve electrodes which distribute and retard the current. One more word about retardation. For an impulse from toe to brain and back to muscle there are three to ten relays from neuron to neuron, and at different levels in the switchboard of the cerebrospinal axis such an impulse is switched across to the motor side or co-ordinated. These relays, conditions of insulation, electric reaction of cables, galvanic elements in nerves; resistance in conductors, relays, end plates, etc.; all these factors are concerned in the time element of nerve conduction, and they are all electric factors. The limit of one paper will not permit further tracing of analogies.

Is it not significant that you find it necessary in your best text-books to adopt electrical terms? You speak of "Storage of Energy," "Discharge of Energy," "Currents," "Cells," "Conductors," "Resistance," "Induction," "Dynamic Polarity," etc. I hope you will soon find it right to adopt "Electricity" for "Nerve Force," which is a name that has sprung as a sort of *filius nullus* from "Vital Force," inheriting a little of its supernatural attributes. Seriously, I mean that many seem to regard nerve force as something beyond a natural form of force.

It is in considering the nervous system as a whole that the analogy to electric systems of communication appears most striking. When, fresh from the study of a great work, like Barker's, I picture the nervous system and its mechanisms in living action before my mind, I see beside it the central telegraph system of New York or London, with its radii of lines and cables, telephonic and telegraphic; its multiple switches, batteries, relays, transformers, condensers, resistances, shunts, duplex and automatic circuits; all this mechanism, like the nervous system, transmitting force and translating intelligence from point to point by terminal instruments which move, talk, write, print, light, inhibit, accelerate and regulate, and in a hundred ways doing what is done in the nervous system, and always by means of the same force, the only form of force capable of such vast and varied service.

IMPORTANCE OF THIS CONCEPT.

If the proposition can be accepted that nerve force is electrical it will, I think, advance knowledge. From that point investigators will take a new departure to explore with new light the functions of the nervous system and other scientific fields. Dr. F. Savary Pearce, who approved these views expressed in my papers of 1900, has found the electric and neuronic concept useful in interpreting the manifestations of some diseases of the brain and nervous system.[4]

Professors Loeb and Mathews, advancing from the chemical side, arrived at the point where they found that muscle and nerve force is electric, and at that point we met; I having reached it before them from the electric side by other, but, I think, as certain paths. I have not presumed to invade the technical field of biologic chemistry, in which Professor Loeb has done such admirable work, further than indicated in this paper. I will leave it to Professor Mathews and others to elucidate his views as to the particular form of electricity he finds nerve force to be. If his ingenious view that it is electrolytic can be accepted it will make it still easier to account for the time element in nerve conduction.

SUMMARY.

The construction of nerves has been closely, though unconsciously, imitated in electric cables.

Experiments on nerves should be interpreted according to the electrical peculiarities of cables, and not as if they were bare conductors.

4. See, for instance, his paper, "Some Points on Intracranial Neoplasms, etc.," read at the New York Academy of Medicine, May 21, 1901. Phila. Med. Journal, Nov. 16, 1901.

Nerves are insulated, distributed and arranged like fine electric conductors.

Their purpose and use are the same as the purpose and use of electric conductors, namely, communication from point to point.

They convey some form of force, and there is not such a gulf between its velocity and that of electricity as has been supposed. This force must be electricity because:

1. Electricity is always present when nerves act.

2. Electricity is the form of force that would do the work required. It is the form of force that would work with such construction.

3. Because the terminal and central mechanisms connected with the nerves correspond to the terminal and central mechanisms connected with electric systems of communication and do similar work in sending, receiving, relaying, switching, transforming, accumulating, retarding, distributing and translating impressions.

4. Finally, because electricity, with such construction of conductors and of terminal mechanisms is the only form of force that we know of that would do all the work required.

I therefore maintain that nerve force is electricity, and that it would advance knowledge of the nervous system and its functions to accept this proposition.

These views were regularly presented to medical societies in 1900 and published in the *Pennsylvania Medical Journal* in November, 1900. If they are considered worthy I should value some acknowledgment of their method and priority. The conclusion that nerve force is electricity may have been guessed at before, and some analogy must have been noted by all observers, but I think my papers covered more ground and brought more evidence together than could have been done before, and first clearly stated the logical necessity of the electric concept.

THE ABSORPTION OF ALBUMINS AND GLOBULINS.*

CHAS. T. McCLINTOCK, M.D., PH.D.
DETROIT.

As albumins are non-dialyzable it was supposed until within recent years that they could not be absorbed as such, that they must be digested. The practice of rectal feeding has disproved this. Considerable quantities of undigested albumins are absorbed apparently unchanged.

Is there any such absorption from the stomach or small intestine? Using the ordinary albumins of food it is about impossible to determine this point. Give an albumin by the mouth and attempt to find it unchanged in lacteal or blood vessel—it is all but impossible. The text-books usually state that antitoxic serums given by the mouth are of no value, that antitoxin is destroyed by the process of digestion. This is probably true. It is certainly true that in artificial digestion, as carried out in the laboratory, the antitoxic power disappears.

But may there not be a part of the serum absorbed without undergoing digestion? I believe so. Ehrlich and his co-workers have shown that a suckling may receive a certain degree of immunity from the milk of an immunized mother, i. e., the antitoxin passes into the milk and is absorbed unchanged.

This is the only rational explanation of the well-known phenomenon that the suckling is relatively immune to a number of diseases that attack the older child.

Carrier, as the result of a series of experiments made in the Pasteur Institute, concludes that antitoxin is not affected by ptyalin, that it is slowly destroyed by gastric digestion and rapidly by pancreatin digestion. The clinical experience of some practitioners, who persist in giving antitoxin by the mouth, led me to undertake some experiments on this line. The results I have thus far obtained are far from satisfactory, but they are possibly worth recording.

I gave guinea-pigs hypodermic injections of diphtheria toxin of known strength. The antitoxin was given per stomach, at times before and again immediately after the administration of the toxin. On giving the antitoxin the mouth of the animal was pried open, a few drops of the serum were placed well back in the mouth and forced swallowing was attempted. It was impossible to tell how much was swallowed and what was wasted. Later the serum was forced from a syringe through a tube introduced into the stomach. This is a very difficult procedure with guinea-pigs, owing to the size and shape of the upper part of the alimentary canal.

In one experiment 12 pigs were given varying amounts from 600 to 3,000 units of antitoxin, on the following day they were given 10 to 30 times the minimum fatal dose of toxin. All died.

In another series of 7 pigs, all received about 1,000 units of antitoxin in the morning, in the afternoon 5 of these received another dose, the next day they were injected with from 2 to 10 times the minimum fatal dose of toxin. The 5 pigs receiving the double dose of serum lived, the 2 having but one treatment died.

In the next series 7 pigs were given respectively 2, 5, 10, 15, 25, 50 and 100 times the minimum fatal dose of toxin. They then had 1,000 units of antitoxin per mouth; of these the ones receiving 15 and 100 doses of toxin died, the remainder lived.

The next series of 5 pigs received 2, 5, 10, 15 and 25 fatal doses of toxin. They then had two doses of 5 c.c. each of serum per rectum (much of which was not retained). Of these the two having 15 and 25 fatal doses of toxin died, while three lived.

Seven pigs were kept without food for 16 hours; they then received 1,000 units of antitoxin and toxin in amounts from 10 to 100 fatal doses. One pig receiving 10, another 100 doses of toxin lived, 5 died.

In the next series 10 pigs were given .1 c.c. of a bouillon culture of diphtheria germs; of these 5 were given 1,000 units of antitoxin; of these 4 died. Two were given 2,000 units of antitoxin; these lived; 3 were untreated and died.

It is to be noted that in all of these experiments the pigs received enormous doses of antitoxin, a half-pound guinea-pig receiving an amount that usually suffices for a 50-pound child. But it must also be noticed that they received large doses of toxin; further, that the alimentary canal of these animals is not accustomed to the digestion or absorption of animal proteids. The experiments are of more physiologic than clinical interest.

Ehrlich has shown that the proteid poisons, abrin and ricin, are absorbed and produce their immunizing effect when given by mouth. Frazer demonstrates a like action with snake venoms. We know that the active principle of the thyroid passes into the circulation from the alimentary canal. Apparently the active principle of the suprarenal gland resists digestion and is absorbed as such.

These experiments appear to show that under certain conditions antitoxic serum may be absorbed as such, but

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. A. Stengel, Winfield S. Hall and Frank B. Wynn.

the variations are so great in the experiments recorded, the results so uncertain, that one could not recommend the method for use. As the serum can be absorbed under exceptional conditions at least, I then began a series of experiments to try and determine what were the conditions necessary for absorption. These experiments are not yet completed, but the results have some interest, and I will give them in brief.

In the first series dogs weighing approximately 10 kilograms were used. The stomach was emptied with apomorphin and the bowels with saline previous to operation. Ether was used as the anesthetic. The abdomen was opened, the stomach and selected parts of the intestines were washed out with normal saline at body temperature. The stomach was tied off at the pylorus, and, after the introduction of the serum, the esophagus was tied. Three sections of the intestines were used: one in the jejunum below the opening of the pancreatic duct, another at the end of the ileum, and the other in the rectum. The intestinal loops were 11 cm. long, and, in so far as possible, their mesenteric attachments were unimpaired, rough handling was avoided, and, after the introduction of the serum, the organs were returned to the abdomen, the opening closed and the abdomen kept warm. After the serum had been in the various organs for one hour, the amount remaining was removed, and the amount of absorption was determined by precipitating the remaining albumin, drying and weighing.

The first experiment was with 0.6 per cent. sodium chlorid. Of this there was absorbed in the one hour from the stomach 36 per cent., from the jejunum 70 per cent., ileum 50 per cent., rectum 75 per cent.

The next experiment was with diphtheria antitoxin. This was diluted with 0.6 per cent. sodium chlorid, in some cases using 3 volumes of this to 1 of serum, in other cases 4 to 1. In the stomach was placed 125 c.c. of this mixture, in the loops of the intestines 20 c.c. After one hour 55 per cent. of the albumin was absorbed from the stomach, 45 per cent. from jejunum, 40 per cent. from ileum, 40 per cent. rectum.

In another like experiment with normal horse serum, the absorption was from stomach 48 per cent.., jejunum 59 per cent., ileum 60 per cent., rectum 54 per cent.

I then tried to see the influence of various drugs and medicines on the rate of absorption. With sherry wine, the mixture containing 25 c.c. antitoxin, 62½ of wine, 37½ bf .6 per cent. sodium chlorid the absorption from stomach was 45 per cent., jejunum 45 per cent., ileum 50 per cent., rectum 18 per cent. The mixture used in the above experiment contained 20 per cent. alcohol.

In a mixture containing 5 per cent. of alcohol the absorption from stomach was 55 per cent., jejunum 60 per cent., ileum 60 per cent., rectum 51 per cent. In a mixture containing 20 per cent. of brandy, or 10 per cent. of alcohol, absorption from stomach was 50 per cent., jejunum 70 per cent., ileum 85 per cent., rectum 73 per cent.

Next a mixture with a small per cent. of oil of peppermint was tried, and the absorption from stomach was 45 per cent., jejunum 76 per cent., ileum 73 per cent., rectum 45 per cent.

Next tincture of opium was added. The mixture placed in the stomach contained 2 c.c. of this in 125 c.c., that in the intestine 1 c.c. in 20. The rate of absorption was as follows: From stomach none, jejunum 80 per cent., ileum 70 per cent., rectum 60 per cent. A second dog gave stomach none, jejunum 64 per cent., ileum 71 per cent., rectum 69 per cent.

In the next experiment chloretone was used. One hundred c.c. of a saturated aqueous solution, 25 c.c. of serum in stomach and proportional amounts in intestines. Absorption from stomach was 38 per cent., jejunum none, ileum none, rectum none. On a second dog there was absorbed from stomach 38 per cent., jejunum 3 per cent., ileum none, rectum none.

With 10 per cent. glycerin absorption from stomach was 2 per cent., jejunum 30 per cent., ileum 24 per cent., rectum none. With 15 per cent. absorption from stomach was none, jejunum 27 per cent., ileum 9 per cent., rectum none.

A mixture containing, as usual, 25 c.c. of serum to 100 of normal sodium chlorid, had added to each of the sections of the alimentary canal 1/100 of a grain of atropin. Absorption from stomach was 12 per cent., jejunum 56 per cent., ileum 61 per cent., rectum 59 per cent. Second dog gave stomach 9 per cent., jejunum 64 per cent., ileum 58 per cent., rectum 54 per cent.

In the next experiment carbonated water was used instead of ordinary water. Absorption from stomach was 85 per cent. A second dog gave 80 per cent. The next dog with carbonated water gave absorption from stomach 58 per cent., jejunum 76 per cent., ileum 95 per cent., rectum 68 per cent. Another gave from stomach 60 per cent., jejunum 73 per cent., ileum 93 per cent., rectum 45 per cent.

In the next experiment the dog was starved several days to clear the intestinal canal. The mixture was introduced into the stomach with a catheter, no anesthetic being used. In this case there was no means of telling the amount of serum that had escaped from the stomach into the intestines. After one hour 56 per cent. of the albumin introduced had disappeared from the stomach.

The next dog was starved several days and then given a large dose of sodium sulphate to flush out the alimentary canal. A dog starved for the same length of time but without the purgative was used for comparison. There was absorbed from the stomach in the one without purgative 53 per cent., with purgative 60 per cent., jejunum 48 and 57 per cent., ileum 45 and 60 per cent., rectum 50 and 66 per cent. The average absorption after starvation was 49 per cent., and after starvation with previous flushing with sodium sulphate 61 per cent.

In the next three dogs sodium bicarbonate was added to the mixture. In the first and second dogs 2.5 per cent. of sodium bicarbonate the absorption from stomach was respectively 85 and 82 per cent. In the third dog 5 per cent. sodium bicarbonate was added and the absorption was 72 per cent.

In the guinea-pigs the absorption from stomach alone with normal serum and water was 60 per cent., with carbonated water 73 per cent., small amount of sodium bicarbonate 91 per cent., larger amount 65 per cent. The averages were taken from 6 guinea-pigs with each of the different solutions. The average absorption of egg albumin using 6 pigs, was 80 per cent.

These experiments are being continued. So far they appear to show either that antitoxin is not absorbed in the same proportion as the total albumins of serum, or is changed in being absorbed, the majority of the pigs dying when injected with several times the fatal dose of toxin, despite a large absorption of albumins. The result of this I will report later.

DISCUSSION.

Dr. W. Becker, Milwaukee, Wis.—Two years ago I attempted to get some knowledge as to toxins which are formed

in dilatation of the stomach, chronic gastritis, and similar diseases of the stomach. I found that if these filtered toxins were introduced into the venous circulation or subcutaneously into an animal they caused vague and unreliable symptoms, but if they were introduced into the stomach of a dog which had previously been washed with alcohol they showed very regular symptoms. I was compelled to drop the work and nothing was recorded. The introduction of alcohol favors the absorption of toxins on account of its paralytic action on the cells of the stomach. This much can be deduced by the experimental work I did, and it agrees perfectly with the work done by Dr. McClintock.

MODIFICATION OF THE CONNELL SUTURE.

RAYMOND CUSTER TURCK, M.D.

Professor of Anatomy and Operative Surgery, Chicago Post-Graduate Medical School; Director of the Post-Graduate Laboratory; Adj. Professor of Surgery, College of Physicians and Surgeons (University of Illinois); Surgeon to Post-Graduate, Chicago and Samaritan Hospitals.

CHICAGO.

Any method of intestinal anastomosis to be of value must, or should, combine, first, an absolute insurance from primary leakage of bowel contents; second, permanent strength of intestinal union; third, preservation of bowel lumen without creation of diaphragm; fourth, simplicity and rapidity of insertion. The fourth condition, however, is of relatively minor importance.

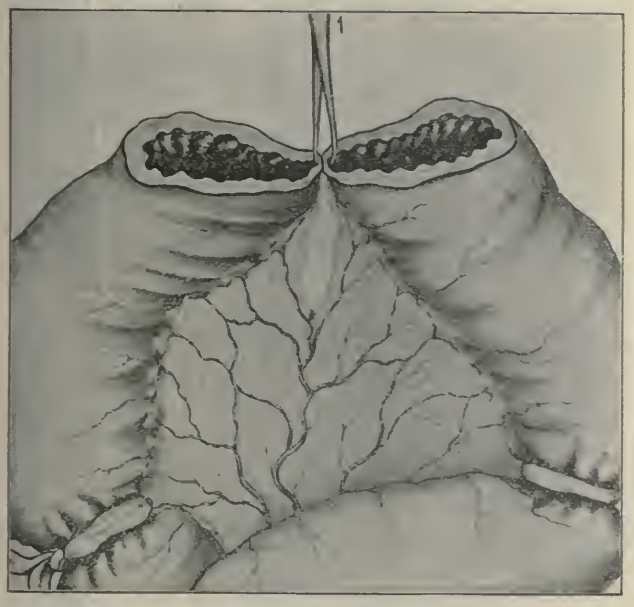

Figure 1.

At the Post-Graduate Laboratory of Anatomy and Operative Surgery there have been performed by the faculty and students, during the past three years, over 2,000 intestinal operations on living dogs, the results of which have been more or less carefully noted. In the course of this series practically all known procedures for the suture or anastomosis of all portions of the gastro-intestinal tract have been worked out, and their advantages and disadvantages demonstrated.

It is not out of the way to state here that work on the dog is a much more severe test of sutures, or of an intestinal operation, than work on the living human. From a somewhat extended experience in animal experimentation, and some experience in hospital and surgical work and surgical observation, I can unhesitatingly say that any intestinal operation which can be performed successfully on the dog can be performed with infinitely greater success and safety on the human being.

It is apparently a popular impression that one may do any kind of rough or septic work on a dog with no bad results, and that is more or less true outside of the abdominal cavity. The dog is peculiarly predisposed to peritonitis from leakage or infection. One may, however, do any intestinal operation on a dog in a barn without regard to asepsis, and the dog may live, but to obtain results the dog's peritoneum must be handled with care and with greater regard for cleanliness and asepsis than that of the human. The dog will not recover, as does the human in the great majority of cases, after dirty intestinal work with faulty suturing.

The human peritoneum may be soiled with pus in pyosalpinx operations, or in appendicitis, or in work on the gall bladder, or in pelvic abscess, with no bad result in many cases; but minute infection will almost invariably cause death of dogs from general septic peritonitis.

Even the mortality from the use of the interrupted Lembert suture in intestinal anastomosis on the human is small, but that form of suture is extremely unsafe

Figure 2.

and inefficient when applied to bowel work on the dog, it being impossible to prevent leakage of bowel contents, with subsequent death from peritonitis in over 35 per cent. of cases, unless the Lembert is used as Halsted's modification (i. e., Halsted's mattress suture) with the stitches placed very closely together or interlocked (author's interlocking stitch). Any form of continuous suture which embodies the Lembert principle of inversion of cut edges and union of a relatively broad peritoneal surface is greatly superior to any form of interrupted suture, unless interlocked, so far as primary or secondary safety from leakage is concerned. The right-angled Cushing suture is the best of the continuous forms yet devised.

The mortality from the use of the Lembert, or Czerny-Lembert, or Halsted, or other varieties of sutures now largely in vogue is reasonably small, and the results obtained therefrom comparatively good, yet there are forms of suture infinitely superior, and were it not for a tendency to stick to the good, old and tried methods the mortality would be less and the results better. Few operators have not had deaths from peritonitis, the re-

sult of leakage. A death from leakage in intestinal anastomosis under ordinary conditions in this advanced stage of surgical science is never justifiable nor excusable.

It has been demonstrated that, all conditions being equal, through-and-through sutures, i. e., those passing through all coats of the bowel, give greater holding power, better approximation of serous coats, greater ease of application and better primary and secondary union than sutures which include only the outer bowel tunics.

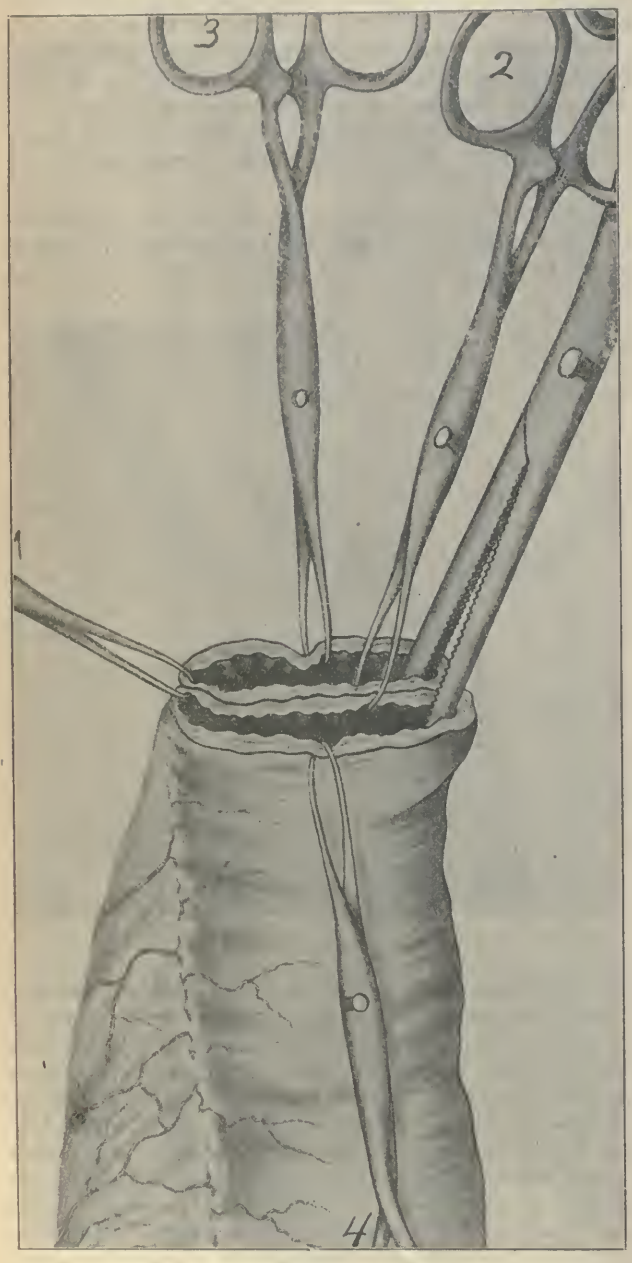

Figure 3.

The suture which is supposed to avoid the mucosa is never uniform, even in the hands of the most experienced operator; while it should include only the serous, muscular and fibrous coats, more often it includes or penetrates the mucosa, or misses the strong fibrous tunic and often has an extremely weak bite in the muscular coat.

The most valid objection to the through-and-through suture is that of infection traveling from within the bowel along the suture to the peritoneal cavity. The Lembert or Halsted may be open to this objection because of the frequent penetration through all of the bowel wall.

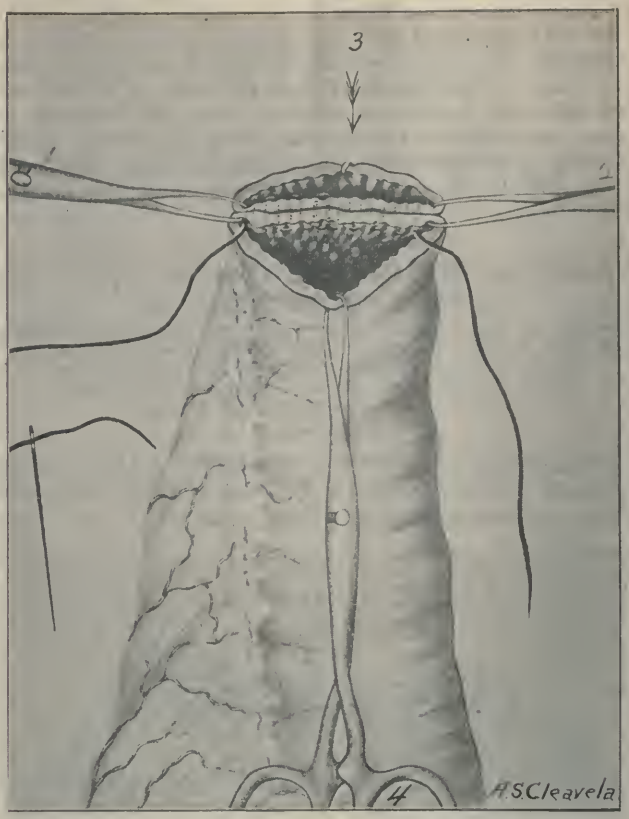

Figure 4.

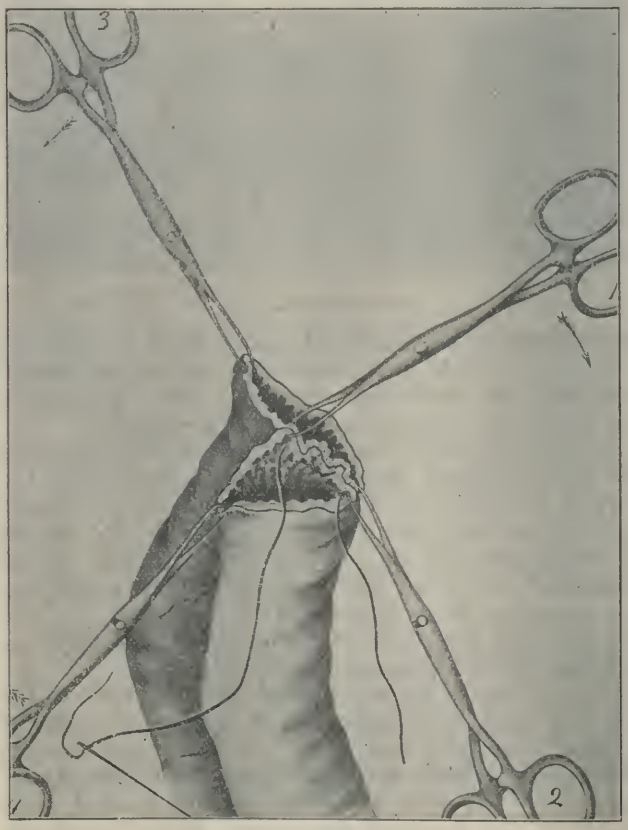

Figure 5.

With the through-and-through suture so placed that that part of it which appears in the peritoneal cavity

is practically of no moment, and with all knots and loose ends on the inside of the gut, no valid objection to it can be raised, and it appears as the safest, strongest, easiest and best of all sutures for the union of divided intestine. This was recognized by Maunsell, and the Maunsell operation for end-to-end anastomosis resulted. The Maunsell operation, however, is complicated and relatively difficult—it requires much manipulation of bowel, and even with extraordinary care there is always grave danger of peritoneal infection during the course of the operation from exposed mucous areas and bowel contents. The aim of the Maunsell operation and its *raison d'etre* is an approach to perfection, but the application of its principles admits of much improvement.

The suture devised by Dr. F. Gregory Connell is a modification of Maunsell's; it embodies the principle of through-and-through stitching, with very firm primary and secondary sero-serous approximation, with practically no suture material leading from the inside of the gut to the peritoneal cavity, and with all knots and loose suture ends on the inside of the bowel.

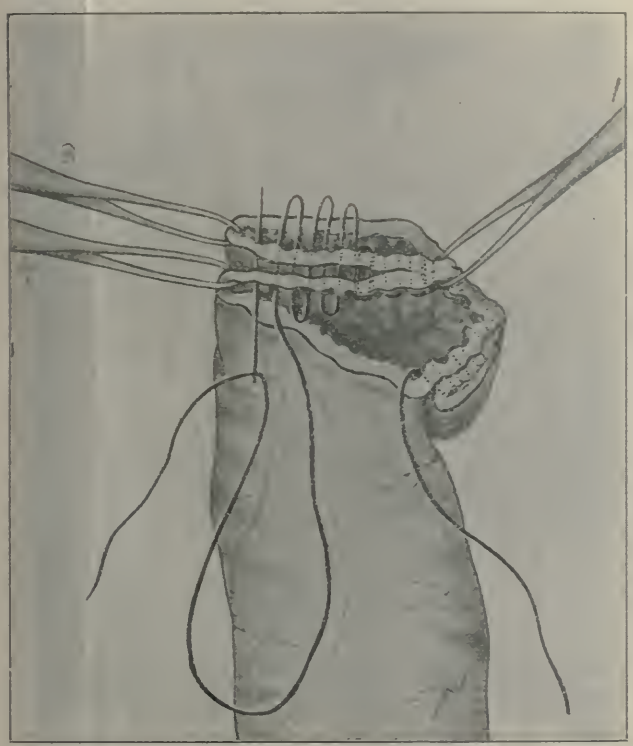

Figure 6.

The method of procedure greatly lessens the manipulation of gut and risk of infection, and does away with the Maunsell inversion of both bowel ends through an opening in the side of one bowel loop. The Connell suture is simple and easy of application when once thoroughly understood. Students have done a complete end-to-end anastomosis by the Connell method in eight minutes. At the Post-Graduate Laboratory there have been done by the faculty, by students working under a demonstrator, by students working alone and by independent investigators, over 400 end-to-end anastomoses by the Connell method with a mortality of less than 3 per cent. At the hands of experienced operators and those of our students who have taken courses in abdominal surgery, with the Connell suture properly applied, the mortality directly traceable to the anastomosis, *per se*, is *nil*.

The Connell suture has been used on the human with unvarying success by operators who have understood it and who have properly applied it. No deaths have yet been reported as due to faults in the method.

The writer has heard and read a very few harsh criticisms of the Connell suture; that it was difficult to apply; that the inversion of the cut edges of the bowel during the last stage of the suturing was incomplete; that the union at the mesenteric border was unsafe, and that the tying of the last knot was altogether a complicated and unwarranted procedure and one on which

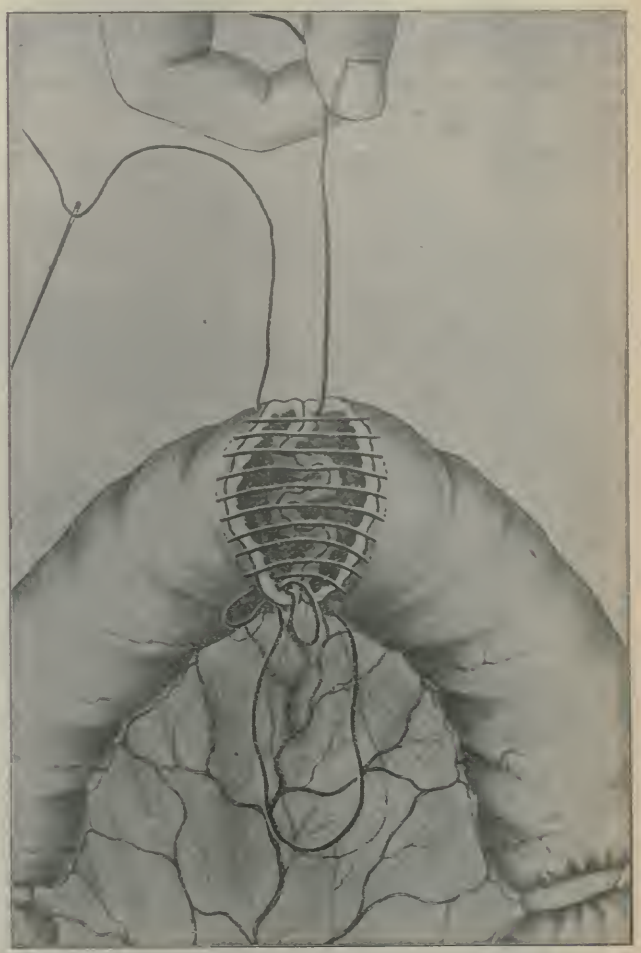

Figure 7.

no self-respecting and busy man could afford to spend time in mastering. A careful study of the method, a résumé of the work already done and the results obtained therefrom quickly demonstrate that the fault lies, not with the method, its technic, or its practical application, but in the lack of understanding and knowledge of the critic.

The Connell method of suture is not easily understood unless actually demonstrated or performed on intestine. It is difficult to illustrate or describe in a way which will show its simplicity and not confuse the reader. The most confusing features, in its description as well as in its actual application, is the method of placing the four tension sutures, which are of no importance so far as the vital principles are concerned, and the method of tying the last knot so that the knot will be on the inside of the gut.

The writer has modified a form of small tenaculum forceps (Fig. 11) which do away with the tension sutures

to good advantage in manipulation and understanding, and has devised a ligature carrier (Fig. 12) which simplifies the tying of the last knot.

The steps of the operation for end-to-end anastomosis are as follows:

First Step.—(*a*) Bring the mesenteric borders of the bowel ends together, as shown in Fig. 1. (*b*) Take a small bite with forceps 1 through both bowel ends immediately at the mesentery (Fig. 1), close forceps.

Second Step.—(*a*) Hold forceps 1 in left hand, lay bowels side by side (Fig. 2). (*b*) Have an assistant insert one blade of an ordinary hemostatic forceps in each loop; holding forceps vertically, make gentle traction away from forceps 1 (Fig. 2); this will put the bowel ends on the stretch and bowels will be laid evenly side by side. (*c*) A trifle more than one-half of the distance from the mesenteric to the opposite border of the gut place forceps 2, as shown in Fig. 2, taking small bite through the contiguous walls of both bowels.

Third Step.—With the bowel ends still gently stretched and lying evenly side by side, place forceps 3 and 4 on the cut edges of the outer bowel walls, each exactly the same distance from the mesentery as forceps 2 (Fig. 3). Remove the hemostatic forceps. (The four forceps are now in the positions of the four Connell tension sutures and are to be used simply for holding the gut to facilitate sewing.)

Fourth Step.—(*a*) Have an assistant hold forceps 1 in his right and forceps 2 in his left hand, pulling gently in opposite directions; drop forceps 3 and 4 (Fig. 4). (*b*) Proceed to suture that portion of the bowel ends between forceps 1 and 2 with a continuous through-and-through right-angled suture, using a straight round needle. Begin at forceps 2 and suture toward forceps 1. Tie the first completed loop of the right-angled suture and *leave the end long* (Fig. 4); continue the suture to forceps 1, taking care to make a back stitch on every fourth loop to prevent the suture from drawing and puckering the gut; continue the suture a trifle beyond forceps 1, taking care to pass beneath the point where the forceps are fast, and to make a complete back stitch at this point—the mesenteric border is always the point of danger in any suture—as the suturing proceeds keep the thread taut to insure close approximation of serous surfaces.

Fifth Step.—(*a*) Drop forceps 2, or it may be removed at this stage. (*b*) Have the assistant take forceps 1 in his right hand and forceps 3 and 4 close together in his left hand, drawing forceps 1 to the right and forceps 3 and 4 to the left (Fig. 5 shows forceps in transit, the arrows indicate direction of the traction), thus placing the bowels from 1 to 3 and from 1 to 4 together (Fig. 6). (*c*) Continue the suturing along from forceps 1 toward forceps 3 and 4 and a trifle beyond and beneath forceps 3 and 4 (Fig. 6).

All forceps are now to be removed and the bowel straightened out. Over two-thirds of the suturing will be completed at this stage and the remaining opening is to be closed by the through-and-through suture, applied in such a way as to completely invert the cut edges. The end of the suture which was tied and left long may be used as a tractor for one side. As the

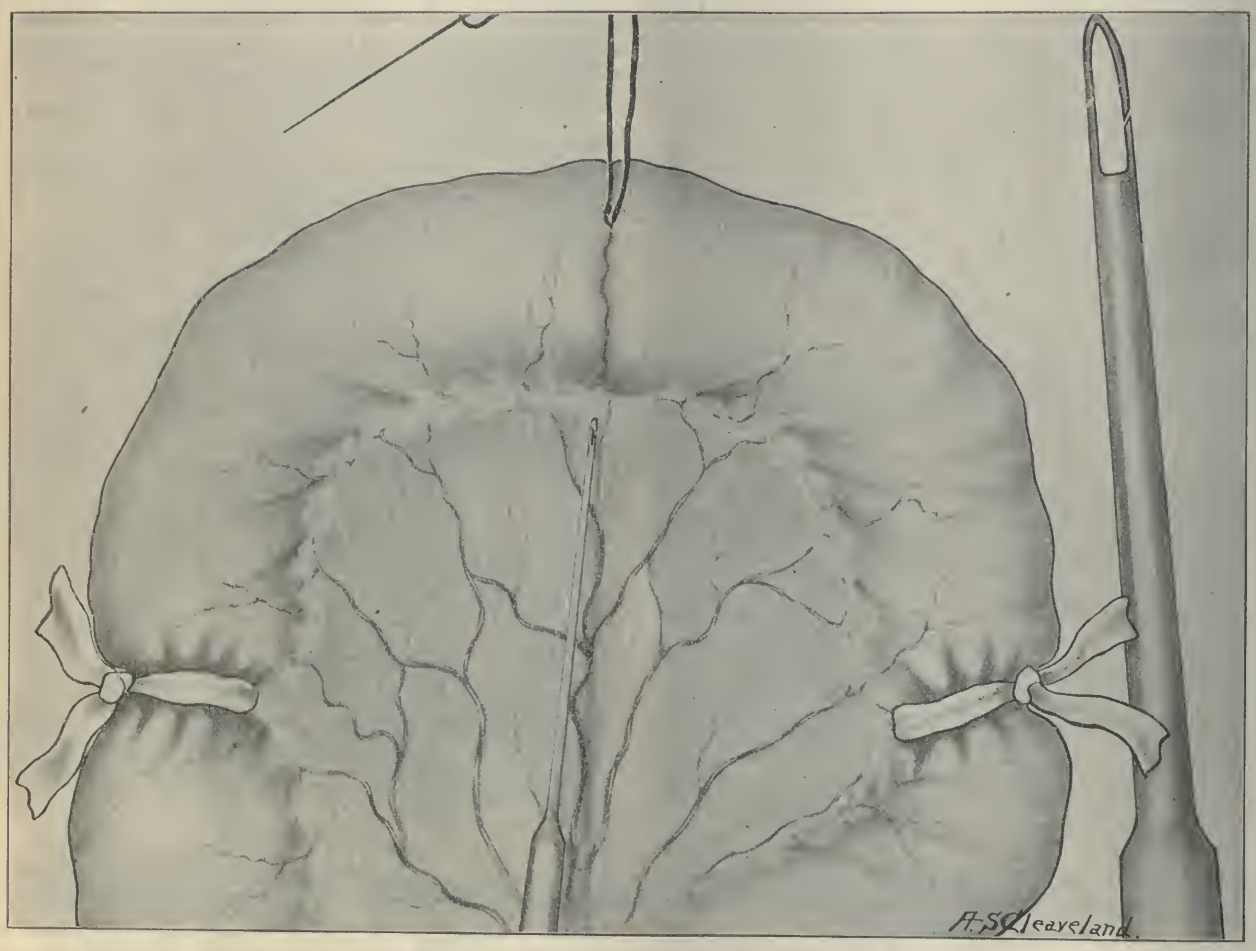

Fig. 8.—Note the spring eye in ligature carrier.

suturing proceeds keep the thread pulled fairly taut as before, thus keeping the sutured bowels snugly together and at the same time providing a tractor for holding the gut in position.

is all closed, when the beginning and end of the continuous suture will be together; leave the *free end longer* than the tied end so that they can be readily identified.

Care must be taken during this last stage, as in every

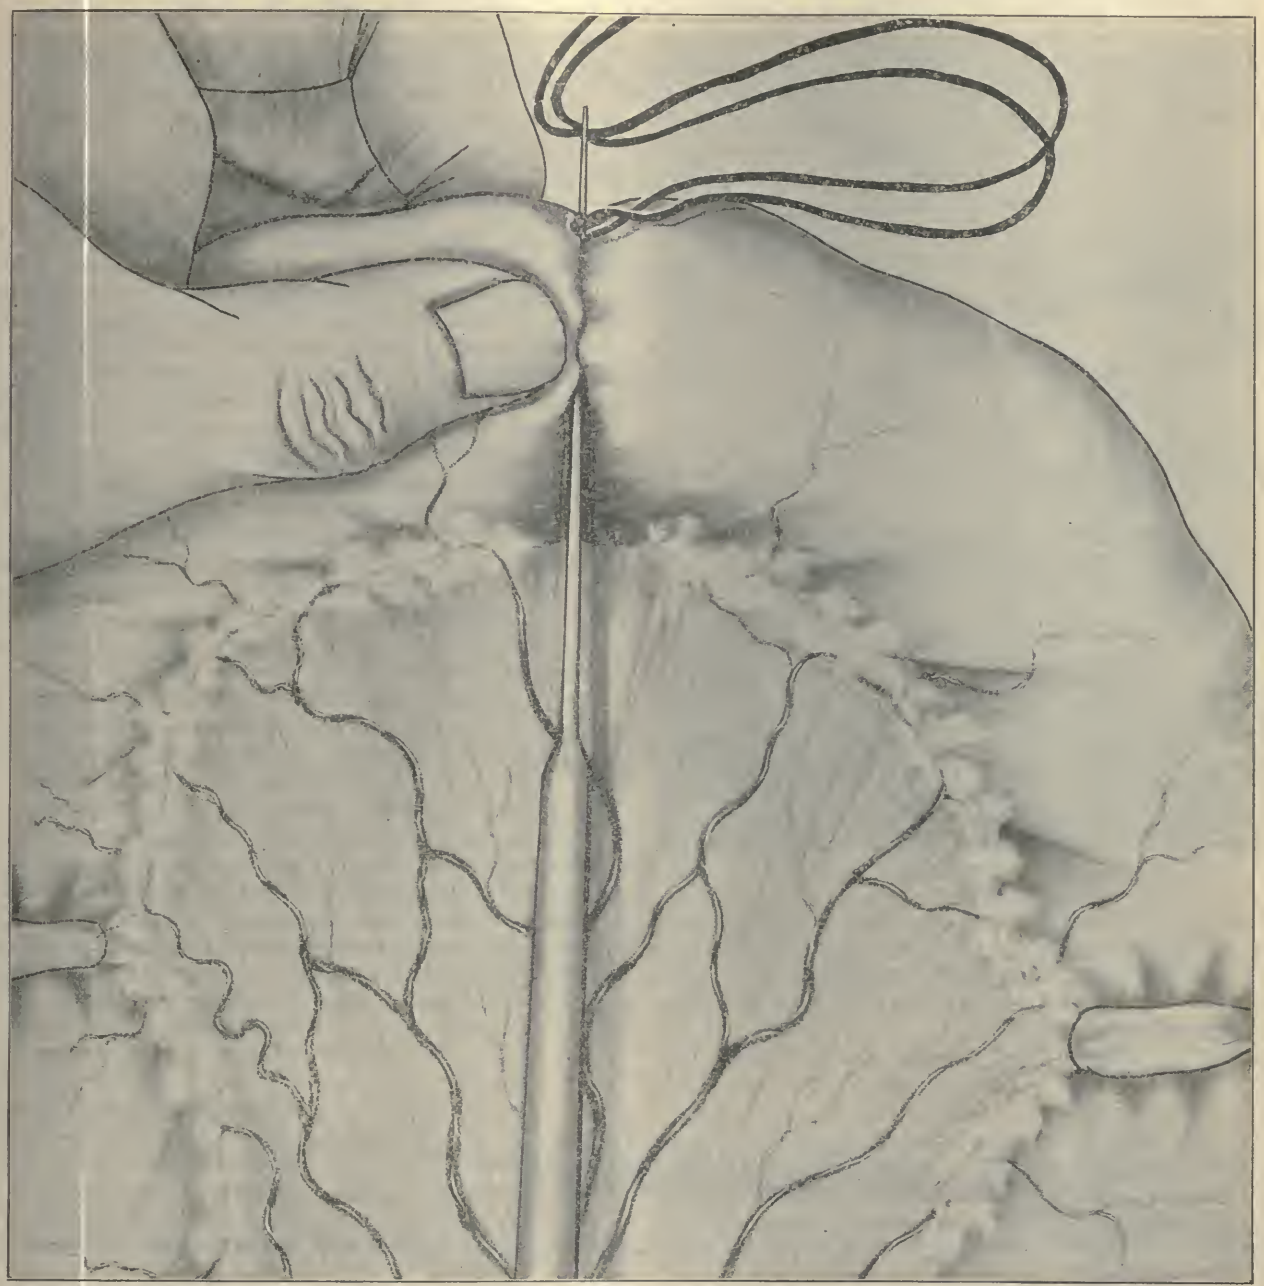

Figure 9.

Sixth Step.—Suture the remaining opening by applying the continuous right-angled through-and-through suture on exactly the same principle as if the bowels were laid side by side (Fig. 7). During the first step, when the bowels are held side by side, it should be noted

other case of through-and-through suturing when the bowel edges are not held firmly, that the suture penetrates all coats of the gut. When the bowel has been divided there is always an eversion of the mucosa with retraction of the serous and muscular coats—this must

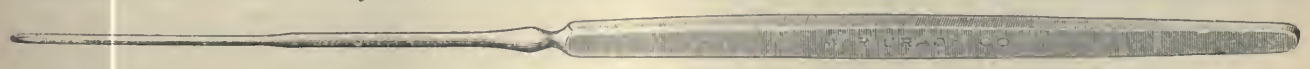

Figure 12.

that the needle passes from *within* bowel A outward, thence from without bowel B inward, then from within bowel B outward, and from *without* bowel A inward, thence from *within* bowel A outward, and so on, so that the *loop* is always on the inside of the gut. Carry out this method, inverting the cut edges until the opening

not mislead the operator into taking a bite through the mucosa only.

Nothing remains now but to tie the knot so that it shall lie on the inside of the gut.

Seventh Step.—Carefully insert the ligature carrier between the sutured edges from one-half to three-fourths

of an inch away from the point where the long suture ends emerge (Fig. 8); bring the carrier out exactly in the small opening between the long suture ends, thread both suture ends in the carrier and withdraw the instrument from the bowel (Fig. 9); pull the suture ends

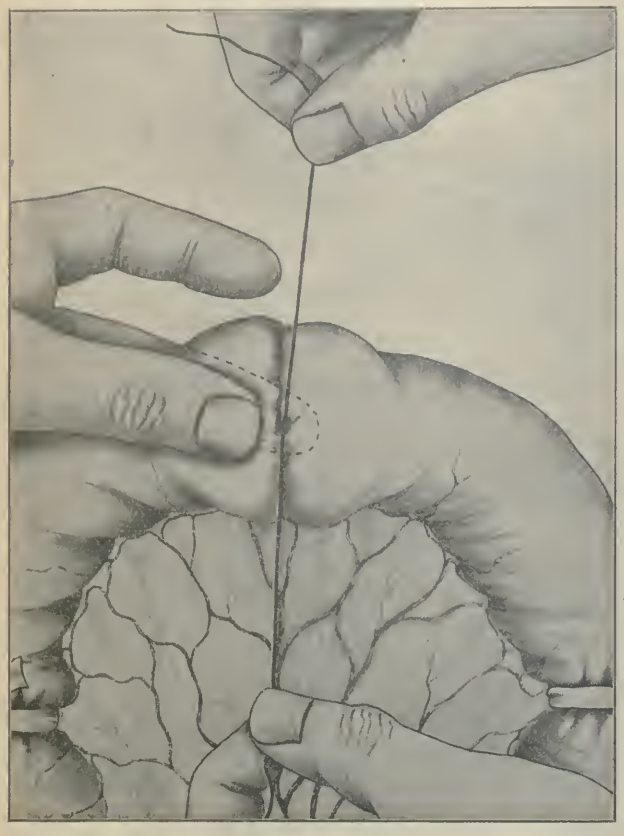

Figure 10.

entirely out through the place where the carrier entered and pull gently on the *long end only* until the two sides of the bowel are closely approximated and the bowel ends are entirely inverted. Tie the ends tightly together

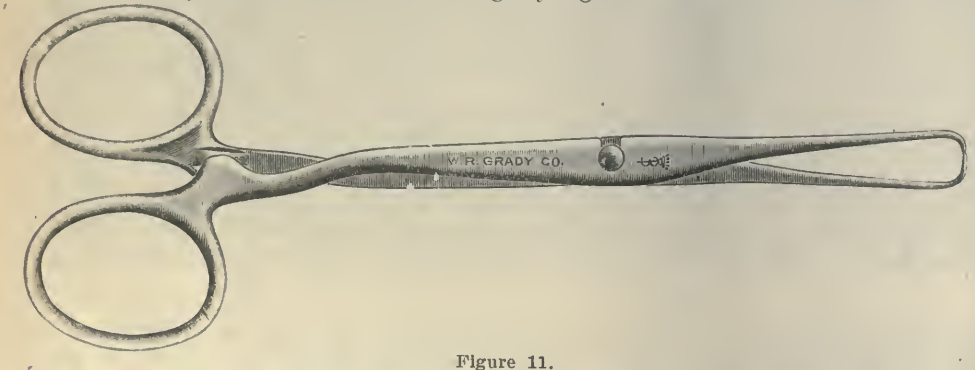

Figure 11.

with a surgeon's knot and cut ends short (Fig. 10). Roll the bowel gently between the fingers, the knot will slip through between the sutured edges and the bowel will regain its normal contour.

103 State Street.

Political Honors for Medical Men in Switzerland.—As THE JOURNAL has previously stated, the president of the Swiss republic is a physician. He is now serving his third term. He was elected to the National Council in 1867, and has served as legislator or member of the cabinet since. His salary as president is less than $4,000. The representative of Switzerland in France is also a physician, Dr. Lardy.

THE IMPROVEMENT OF GENERAL ANESTHESIA ON THE BASIS OF SCHLEICH'S PRINCIPLES:

WITH SPECIAL REFERENCE TO ANESTHOL.

WILLY MEYER, M.D.

Professor of Surgery at the New York Post-Graduate Medical School and Hospital; Attending Surgeon to the German and New York Skin and Cancer Hospitals; Consulting Surgeon to the New York Infirmary.

NEW YORK CITY.

(Concluded from p. 556.)

ADMINISTRATION.

It is not my intention to give you any statistic data concerning the effect of anesthol in the various cases. Working as I do at a number of hospitals, with their continuously rotating house staff and consequent change of narcotizers every few months, such statistics would be of little value. I should, however, like to narrate briefly what experience has taught us in connection with the administration of the drug. Anesthol should be administered by the drop method, the same as all other drugs used for general anesthesia, first rapidly, later slowly.

After considerable experimentation we now drop it on an Esmarch mask with a double frame, which is covered with a doubly-folded piece of sterile gauze and a piece of oiled silk or Mosetig batiste. The latter has an opening about the size of a silver dollar in the center. It is true some of the anesthetic is thus wasted, but in return the patient besides always inhales a sufficient amount of fresh air.

If administered drop by drop the subject is easily brought under the influence of the anesthetic. There is no struggling during the induction of anesthesia. If, on the other hand, anesthol be poured indiscriminately on the mask, especially during the induction stage, the patient may suddenly turn pale and respiration may become shallow or even to all appearances cease altogether for a little while; yet, the heart will be found to be but little influenced, the pulse continuing to remain full and strong, in agreeable contradistinction to chloroform with its sudden syncope. My experience has always been that if anesthol was given in too large doses by an inexperienced narcotizer it affected the respiratory center and not the circulatory. I have never had the narcotizer tell me, in the course of these four years: "Doctor, the pulse is weak," if by chance the anesthesia was not as satisfactory as desirable. The remark made in such an event was invariably: "Doctor, the patient does not breathe well." A short, rhythmic pressure on the abdomen or artificial respiration with the mask entirely removed would, in these instances, soon restore normal conditions.

I would, however, here especially emphasize the fact, that such accidents can be entirely avoided if the narcoses be carefully conducted. On the other hand, shallow breathing should not be mistaken for inhibition of breathing. So long as the patient's pupils were contracted and his lips red I did not share the alarm of the young narcotizer and have never considered artificial respiration called for. An inexperienced narcotizer may think that his patient has stopped breathing, when

respiration has merely become shallow. Removal of the mask, thus allowing the patient to breathe pure air for a few moments, will soon restore to normal the temporarily apparently alarming condition. Of course, if anesthol were continuously poured on the mask I am sure the narcotizer would succeed in killing his patient, even with this, I think, the safest of all anesthetics.

As soon as the second stage of general anesthesia has been reached, one or two drops every 2 or 3 seconds suffice in the hands of an experienced and efficient anesthetist to properly keep the patient under the influence of the drug. The administration by drops must be regularly continued throughout the narcosis.

DEEP ANESTHESIA IS NOT CAUSED.

In view of the fact that, according to Schleich's reasoning, the body stores very little of an anesthetic the B. P. of which corresponds, or nearly corresponds to its own temperature, since the patient exhales almost as much of the drug with each expiration as has been previously introduced into the blood on inspiration, anesthesia is thus merely kept going. The patient is kept just sufficiently under the influence of the anesthetic to enable the operator to conveniently do his work. The patient never is any more deeply narcotized than is necessary for the surgeon to perform his operation. In consequence of this almost complete equilibrium that is maintained between addition and loss, it sometimes took us some time, in the beginning of our clinical research, to reach the second stage of anesthesia. It also frequently happened that the patient never completely lost the reflexes, especially in abdominal operations, no matter how profoundly he seemed to be narcotized. As soon as, for instance, traction was made on the stomach or on the omentum, say in the case of gastroenterostomy, the patient would resist.

THE ADDITION OF MORPHIN.

On the strength of this clinical experience we introduced the administration of a hypodermic of 1/12, 1/8 to 1/4 of a grain of morphin, according to age, without atropia, one-half to three-quarters of an hour before beginning anesthesia in all abdominal cases. This procedure worked like a charm, so much so that a few months later, in the fall of 1899, we made this hypodermic administration of morphin prior to anesthesia a standing rule in every case, no matter what the nature of the operation.[15] This wrought immense improvement. Induction of anesthesia was more speedily accomplished and the second stage quiet; much less of the drug was required. If the reflexes were still pronounced in spite of the previous hypodermic injection, an additional dose of morphin of proportionate amount was injected during the operation. This had the desired effect, even in alcoholics, who by this means respond favorably to anesthol administration.

Still, in combination with morphin, anesthol must be continuously administered, drop by drop, during the entire course of the operation. If this be not done some patients will begin to retch or to vomit, just as we are accustomed to see it after the use of other anesthetics, particularly chloroform. If, in such an event, the amount of anesthol administered be gradually increased the vomiting during the operation promptly ceases. This phenomenon has been observed in every instance.

With the continuous drop method and a previous hypodermic of morphin not much of the drug is required, and the patient may be kept under its influence for hours with a comparatively small amount. Salivation and mucous râles never occur. There is no cyanosis. The patients appear to be in a deep natural sleep. Awakening is usually quick, just as was observed with Schleich's mixtures. The patients regain their mental faculties in an astonishingly brief space of time; they often awake while still on the operating table and intelligently respond to questions. Since receiving a preliminary morphin injection they now first sleep for a while after they come out of the anesthesia, but can be easily aroused.

SEQUELÆ.

As to sequelæ: vomiting is varying. I have had many patients who did not throw up a single time; others, again, vomit just as often as frequently happens after chloroform or ether narcosis. On the whole I think, however, that vomiting after anesthol is rare, and at no time as persistent, compared to the frequency of its occurrence after the administration of other anesthetics. Headache, general malaise and general systemic affections, so often witnessed after chloroform or ether anesthesia, are very rarely met. Not in a single case have I seen bronchitis or pneumonia as a result of anesthol narcosis. In a very few instances the symptoms of a previously existing nephritis were temporarily slightly increased. Heart, lung and kidney affections were never considered a contraindication to the use of anesthol. Of course, wherever local cocain infiltration or spinal anesthesia seemed indicated it was always employed.

DEATHS UNDER ANESTHOL.

In a series of many hundreds of cases operated on within the last four years there have been two deaths during the anesthesia, and these occurred at the end of the operation. Both were operations on hospital patients on the kidney. One was in a man with a large horseshoe kidney and total suppression of urine for six days in consequence of impacted ureteral stones. The operation was rather prolonged, resection of the eleventh and twelfth ribs being necessary in order to bring a very large hyperemic and edematous organ outside of the wound. The obstructed ureter was cleared first, after high ureterotomy; but a number of faceted stones in the calices of the kidney could not be extracted, though the wound had been lengthened into the pelvis. Therefore, section cut of the kidney was made. The assistant compressed the renal artery well, but failed with regard to the vein. A gush of venous blood was followed by sudden absolute anemia of the divided kidney surfaces. The face of the patient likewise turned pale and the pupils became dilated. All our efforts to restore the action of lungs and heart proved futile. The patient had died. Autopsy was refused. Death seemed to me due either to sudden aspiration of air through one of the very large branches of the renal vein or to true shock. The administration of anesthol had been stopped fully ten minutes before this accident.

The other death occurred during a nephrectomy performed on a much emaciated young woman with an advanced tuberculosis of the uropoietic system. When ligating the pedicle of the kidney the patient showed signs of awakening and became restless; deeper anesthesia was ordered. Suddenly respiration and pulse ceased. All our efforts at resuscitation were in vain. Here, too, autopsy was refused. It is possible that the sudden administration of a larger quantity of the anesthetic towards the end of a difficult operation proved too much for the patient's general condition, and suddenly

15. It is highly interesting to me to read in the report of the proceedings of the Congress of German Surgeons, in 1901, that Mikulicz advocates the administration of a hypodermic of morphin previous to inhalation narcosis.

increased the shock to a point where medical help was powerless. I feel confident, however, that the result would have been the same with any other kind of anesthetic.

OBSERVATIONS OF DR. GUTH.

Dr. William C. Guth of New York, who has conducted the anesthesia in the greater number of my private patients outside of the hospitals for the last eleven years, and hence has had most favorable opportunities to carefully note the varying effects of the respective anesthetics used from the very beginning to date, states his opinion regarding anesthol as follows:

Since Oct. 15, 1898, I have administered anesthol in your private practice as a general anesthetic in 200 cases, and at your suggestion I took extensive notes and kept a detailed record of all these cases, noting particularly the amount of anesthol administered to induce anesthesia, the total amount of the anesthetic employed in each case, the behavior of the patient from the time of the administration of the anesthetic to return to consciousness; also noted, as far as practicable, the respiratory, cardiac and renal conditions prior to, during and following such narcosis. In addition I have made such observations and entries in the record as were suggested and outlined by you.

Having had, therefore, during this period (3½ years) the opportunity of carefully noting the effects of anesthol, we are warranted in drawing conclusions as to its place and value among anesthetics and comparing its action and its advantages, if it possess any, with chloroform, ether or combinations of chloroform and ether.

I have observed that anesthol, when administered by the "drop-by-drop" method (employing an Esmarch or Schimmelbusch mask, covered with sterilized gauze and oiled silk with central opening) surgical anesthesia is established in the majority of cases in about 8 minutes. In those instances in which morphin (without atropin) was administered hypodermically about three-quarters of an hour previous to the introduction of anesthesia, the primary stage of anesthesia very frequently was established in a few minutes less time. We have noted, too, and we may stamp it as one of the agreeable and distinctive features of anesthol anesthesia when so conducted (i. e., preceded by morphin hypodermically) that the stage of excitement is practically eliminated from the primary stage of anesthesia; also, that in the transition from this stage to that of the complete surgical degree the patients in every instance enter into the latter stage gradually, never suddenly or with the next inspiratory effort, as is frequently observed in chloroform administration. Neither have we noted in this transition stage any sudden fall in pulse rate, the change to the slower, fuller pulse coming on gradually. Complete anesthesia having been gradually induced, the pulse is full, slow, regular (of the chloroform anesthesia type) and the respirations regular, full and not stertorous.

In no instance has there been an increase in salivation or bronchial mucus during narcosis. The face presents a healthy color, there is no pallor, and if the anesthesia be administered on the mask described, by the "drop-by-drop" method, cyanosis never occurs. Of course, if the anesthetic be administered carelessly or poured on the mask in an indiscriminate and indifferent manner, the danger of inviting serious and possibly disastrous results from overdose threatens. To accomplish an approach to an ideal narcosis for the surgeon's purpose and that with the least risk of subjecting the patient to undue anesthetic shock, anesthol must be administered with the same care and judgment necessary in conducting any general anesthesia.

As I have stated, to obtain the most satisfactory anesthesia, anesthol should be administered "drop by drop." This term, familiar to all anesthetists, may call for elucidation as applied to anesthol anesthesia. On consulting my records you will note that on an average 8 to 10 grams of anesthol were employed in about as many minutes to induce primary anesthesia and that throughout the administration of this agent, the drop-by-drop method was continued at about the same rate, so that, in a general way, we may say, for an operation of the major type, when complete muscular relaxation is to be maintained throughout, 60 grams of anesthol will be consumed in the course of an hour, or about one gram a minute, if administered drop by drop.

When given in the manner described, we have found in almost every instance, even in cases of prolonged anesthesia, that consciousness returns in a very few minutes after the withdrawal of the mask and frequently we have noted that the patient became fully awake and responded promptly and intelligently to questions, while still on the operating table during the application of outer surgical dressing.

Vomiting occurs in a small percentage of cases after return to consciousness; it is not of a prolonged or distressing type as far as I have been able to elicit. As with chloroform, if the patient be insufficiently under the influence of the anesthetic, retching or vomiting will occur during the administration. This condition is remedied by persisting in the administration of the anesthetic and not by pushing or crowding it.

Among cases recorded, you will note that several had chronic bronchitis or nephritis before operation, in all of which anesthol was administered with the happiest anesthetic result. There have been instances, too, of serious valvular cardiac lesion, atheromatous cases, diabetes, profound anemia and anemia with severe surgical shock, in which the anesthesia was most satisfactory and in which, contrary to what might have been expected in such instances, a better circulatory and respiratory condition was induced during the anesthetization. In but one instance, that of operative intervention for surgical kidney, I have noticed embarrassed respiration with cyanosis. This condition probably was due to the position of the patient on the table at the time of operation, for, on changing the position, these manifestations ceased and normal respiration and healthy color returned.

Résumé.—It will be found that in a patient under the influence of anesthol, respiration is slow, quiet, full; there is no excessive secretion of saliva or of bronchial mucus; the face is not flushed, neither is it pale; its color may be described as normal; the pupil is contracted as in chloroform narcosis; the pulse is slow, full and regular. Complete muscular relaxation is established and maintained. Anesthol combines the good effects of chloroform and ether and has its advantages over both as will be seen from the following: In no instance have we noticed any sudden or alarming changes in pulse rate, volume or pressure. In every instance the patient was brought to the stage of complete anesthesia gradually and progressively. Thus has been eliminated that source of concern of the anesthetist as is frequently met in chloroform narcosis, that, even when that anesthetic has been most skilfully administered, the patient at one moment appears to be but superficially narcotized while with the next inspiration or two a most profound anesthesia ensues with disturbed pulse rate and pallor. Pulmonary and renal complications have not in any case followed the administration of anesthol, and where they have existed prior to the use of it, they have not been aggravated. The return to consciousness is prompt; in fact, frequently strikingly so. The tendency throughout the narcosis is toward recovery from the anesthetic effect, not to an approach toward deeper and profounder anesthesia, hence the advisability of administering it constantly, at a suitable rate and drop by drop. We have observed no instance, even after its prolonged administration, in which the patient had to contend (in addition to reaction from surgical interference) with anesthetic shock.

CONCLUSIONS.

Summing up I would say: Believing Schleich's principle of improving general anesthesia on a physical rather than chemical basis to be correct, I consider anesthol—produced as it is in true conformity with this principle—to be the least dangerous of all anesthetics thus far known, as they are employed for regular narcosis in the daily work of the surgeon. I therefore be-

lieve it worthy of the most careful consideration of every physician employing anesthetics.

No doubt M.S. possesses great advantages over pure chloroform or sulphuric ether and is an excellent anesthetic, but in the light of the presumed correctness of Schleich's reasoning, outlined above, M.S. or any other combination of anesthetic drugs, the boiling point of which does not correspond to the temperature of the human body, can not be considered as safe as anesthol.

The improvement in general anesthesia brought about within the last few years has been manifold. Primary administration of nitrous oxid, followed by ether oxygen anesthesia, carried out by expert anesthetists such as New York may well be proud of, means a great step forward in the right direction. The same is true in regard to the efforts on the part of the various staffs of attending physicians and surgeons of our large hospitals, to create a paid position for permanent narcotizers. No doubt the future will see such experts in place in every well-conducted hospital, and thus put a stop to the jeopardizing of the lives of our patients by the inveterate method of having the youngest doctor, fresh from college, untrained and inexperienced as he is, attend to narcoses.

However, in private practice and in places remote from the larger cities, such expert anesthetizers can not always be at our disposal. The country doctor must carry the anesthetic in his valise; he can not regularly employ a second man, who carries with him the cylinders filled with nitrous oxid, nor can he himself bring along the large though ingenious and useful rubber bags, enabling the doctor to administer ether in a better and more scientific way than is possible with the paper and towel cone.

Here simpler appliances with regard to mask as well as the anesthetic are needed. Ether and chloroform administered with the help of uncomplicated masks or cones have carried the field so far. Anesthol, as has been demonstrated above, being a true solution, not a mixture, may thus well be employed in these cases in place of the former certainly more injurious pure drugs.

I should be pleased, indeed, if these lines should induce others to try anesthol, and they should get from their patients so gratifying a description of their subjective impression as I recently received from a colleague, on whom I operated at his home three times in close succession for a rapidly spreading phlegmon of hand and arm resulting from a finger infection. In each instance the anesthesia was conducted with anesthol preceded by a hypodermic of ¼ of morphin. His words to me after this threefold experience were these:

"You take it (anesthol) without knowing what you are taking, and when you awake you do not know what you have taken. It does not annoy you; it does not make you sick. It is simply a question of falling asleep and waking up."

The Need of Organization.—Dr. James C. Johnston, in the *Philadelphia Medical Journal*, says: "The worst of the many evils with which the medical profession has to contend is one of which all our national experience has taught us the folly, decentralization. It is evident throughout. Its business is worse handled than any other. Instead of trusts, in which overproduction is restrained, in which wages can be fixed and maintained, and in which the incompetent and superfluous are eliminated, it is every man for himself and the devil and his colleagues for the hindmost. This is true of its material for investigation and of the journals it supports, as well as actual practice."

FEVERS OF DOUBTFUL NATURE IN INFANCY.

PRELIMINARY CLINICAL NOTE.

J. L. DUENAS, M.D.

Attending Physician to the Children's Ward, Hospital No. 1; Visiting Physician of the Training School for Girls of Cuba; Children's Physician in Tamayo Dispensary.

HAVANA, CUBA.

In the island of Cuba the febrile process is found with extraordinary frequency during infancy and childhood. The meaning of the fever symptom in a tropical country where typhoid fever, malaria, influenza and yellow fever exist in all their forms and varieties has always been a matter of great local interest which has given rise to lively discussions. Not over 20 years ago the diagnosis of febrile diseases was made by the methods of the old clinic, and the anatomic denominations were the ones which prevailed in the nosologic charts.

ALL FEVERS CONSIDERED MALARIAL.

At the time that little was believed in the existence of typhoid fever in this island, and when it was supposed that yellow fever only attacked unacclimated foreigners, the tendency of physicians was to diagnose as malaria all cases where a local cause to the process could not be easily found, or where it could not be referred to another well-defined general disease.

During the decade of 1880 to 1890 the existence of typhoid fever in our towns of importance was well demonstrated pathologically; but notwithstanding many persisted in denying it, continuing to classify as malaria all cases of remittent fever of longer or shorter duration. A true epidemic of malaria-mania spread itself among the physicians to such an extent that seldom a febrile process was not attributed to malaria, even when there were evident signs to explain its origin in a different way. At about that time works were published in other countries intended to exhibit the different forms and localizations of this infection of the blood.

In 1890 I presented to the First Cuban Medical Congress a paper on the use of quinin in Havana, where I tried to refute the tendency to abuse of that alkaloid, particularly in children, and I firmly denied the existence of so many cases of malaria, either as a primary disease or as a secondary process, always supposed to be associated to many other pathologic processes. A very small number of physicians supported my idea at that time.

THE VARIOUS OTHER CAUSES OF FEVER.

In a lecture which I delivered two years later to the "Sociedad de Estudios Clinicos," I initiated a discussion on the several kinds of fever reigning in this city, especially during the hot season, and which attacked children with preference, being then inclined to admit for many of them an infectious cause of intestinal origin. I tried to differentiate them from typhoid fever by their etiology, their symptoms and their course, making saprophytism and endogenic or exogenic autointoxication responsible for some of our types of tropical fevers. I called attention to the cases of typhoid fever in which autopsy did not show the characteristic lesions of Peyer's patches and only the isolated follicles of the large intestine were involved, for which reason these cases were denominated colo-typhus by the ancient writers. I pointed out besides the coincidence of infectious enteritis in infancy during the epidemic of those fevers in children of all ages and young adults, considering colo-infection, as the physicians of Lyon's school did, as an attenuated expression of Eberth-infection.

In 1893, and as a consequence of a dedication to the study of children's diseases, I presented to the First

Pan-American Medical Congress, held at Washington, a paper on "Primary Acute Entero-colitis in Infancy," in which I described the different varieties of types of gastrointestinal troubles in the first years of life, and I called attention to the frequency and predominance among us of the eclamptic, cerebral, gastric and typhoid forms of the ancients in opposition to the cholera infantum which was common in the United States and certain regions of Europe. In that work I demonstrated with facts taken from my personal experience that in that division of pediatrics I had not observed anything in Havana which had not been minutely described in other countries by the old masters of that branch of medicine.

THE INFREQUENCE OF MALARIA.

In the course of recent years it has been proved beyond doubt by means of the observation of the blood that malaria is not frequent in Havana, as I affirmed in 1890, based on the clinical and epidemiologic observation. It has also been proved that the anopheles species of mosquito is seldom found within the radius of the city, being somewhat frequent in the suburbs and much more in the country where cases of acute and chronic malaria are common.

The results of modern scientific investigations have thus brought about a change in the ideas regarding the nature of our fevers. To-day it is accepted in a general way that malaria is not so frequent in Havana; that typhoid fever exists in greater proportion and that, on the other hand, there is a large number of febrile patients in which neither malaria nor typhoid fever can be diagnosed, not only on account of the clinical signs, but also by the constant negative results of the hematologic analysis, as far as Laveran's parasites and agglutination tests are concerned.

The fact that the Island of Cuba is one of the main foci of yellow fever introduces a new element of discussion in the etiology and diagnosis of infantile fevers, inasmuch as clinical and epidemiologic demonstrations have clearly shown the receptivity of the natives, denied for such a long time, for that dreadful disease.

THE DIAGNOSIS COMPLICATED.

I have thought it necessary to make this historical sketch in order to show how divided the opinion of physicians about the nature of our tropical fevers has always been; also to point out the difficulties surrounding the diagnosis of infantile pyrexias in a country where malaria, typhoid fever, influenza and yellow fever exist in their usual forms of epidemic exacerbations, and, where it is necessary to admit at the same time the existence of fevers as yet undeterminated, and which have their origin in the digestive tube and which the developing modern science accepts in all other countries since the intestinal autointoxication doctrine was established to explain the origin of general and organic troubles similar to those produced by other better known specific infections.

THE GASTROINTESTINAL FEVER.

The group of fevers which I intend to describe here constitute two principal types, one of rapid, the other of slow evolution. Both are common to all periods of infancy and childhood, but the younger the child the more frequently the rapid evolutive forms occur. The first type is characterized by feverish accesses most commonly of a depressive rather than of an excitative nature. The disease in many cases attacks the child unawares when he is in excellent state of health; but it is frequently preceded by digestive derangements, diarrhea and simple indigestion, the gastrointestinal symptoms being always more or less apparent. At first vomiting and constipation may exist or yellowish, greenish, thick mucous stools accompanied by redness and irritation of the anus. The tongue is slightly coated and if the child is traversing the dental period stomatitis and throat inflammation may exist to a certain degree. In some cases the symptoms mentioned do not exist, the only phenomena apparent being certain sensibility experienced on pressure of the abdomen, somewhat intensified on the region of the liver and accompanied by muscular contractions.

From the first stage the temperature rises to 104 or more. During the first day of the disease the thermic cycle is sustained or continuous, or interrupted by slight descents followed by new rises. During the succeeding days the temperature follows a different course dependent on the evolutions taking place in the morbid process of the disease, whether in the direction of recovery or death. In the first case the fever assumes a remittent character and in a few days completely disappears together with all other symptoms which gradually disappear at the same time. When the process of the disease must certainly end in death the temperature has a marked tendency to continuity, the cerebral symptoms grow more intensified, convulsive phenomena appear accompanied by coldness of the extremities and suppression of the urine. The little patient may die in the course of 24, 36 or 48 hours.

The causes which in Cuba have always originated discussions on the nature of these cases are:

1. The belief in the prevalence of endemic paludic germs.
2. The possibility existing at present that they may constitute syderant types of yellow fever.
3. The absence of phenomena in the digestive apparatus frequently observed in the early period of invasion of the disease.

In other countries the differential diagnosis of these cases is made on malarial infections, typhoid infections, acute cases of influenza, cerebrospinal meningitis, primary tubercular meningitis, or secondary meningitis of rapid evolution; but in all of them the influence of intestinal infection on the origin of these pathologic cases which are so frequent during the first stages of life, is to-day recognized.

Marfan, Saint Philip, Comby, Escherich, Bagınsky, in Europe; Booker, Jacobi, Starr, Holt, Crandall, and many others, in America, have described the rapid type of these intestinal infections. Modern doctrines compel us to classify these cases as fevers whose nature is still undergoing due study and investigation, so as to bring them to the rank of definitely specified infections. But they correspond exactly to the severe eclamptic, cerebral, meningitic or convulsive forms of acute enteritis, or enterocolitis which are described by such authors of old text books, as: Bouchut, West, Trousseau, Rilliez and Barthez, Meigs, who pointed them out as a very frequent ocurrence during the first two years of life. The diseases are the same. The only difference to be observed is in the denomination which varies in accordance with modern theories held as to its etiology and pathogenic mechanism.

REASONS FOR THE GASTROINTESTINAL FEVER THEORY.

In the Island of Cuba, and above all, in the City of Havana and other localities where malaria is not so frequent, I can assure, after more than twenty years' experience, that the majority of these cases of acute infec-

tions have in infancy a gastrointestinal origin owing to the following reasons:

1. The etiologic investigation allows us to discover among the antecedents of the case, more or less serious transgressions in the dietary hygiene, on the strict observance of which I have greatly insisted in my work on acute enterocolitis, published in the "Transactions of the first Pan-American Medical Congress" (Vol. II, p. 1343). I will here add that in many instances the mothers absolutely deny said origin, but clinical observation reveals abnormal discharges. In some cases they confess the fault incurred and later the exact causes of the intestinal derangements can be discovered.

2. The epidemiologic investigation shows, on the other hand, that the disease is more frequent during the warm weather and coincides with the development of fever of typhic nature, with the different types and varieties of gastrointestinal accidents, in many children under two years of age, and with the remittent prolonged cases of fever in children above that age. Its frequent repetition observed in the same child and always obeying to the same cause, dissipates all idea of typhoid or yellow fever; diseases which do not attack the same person twice in accordance with the opinion generally established and admitted.

3. The bacteriologic examination demonstrates the existence of great number of *Bacillus coli communis* in virulent condition, as well as of other saprophytes in the potable waters of Havana. Very frequently unboiled water is administered to nursing children.

4. The hematologic examination reveals the absence of plasmodies in the blood obtained from these small patients as well as the absence of the serum reaction of Widal.

5. The treatment by means of quinin though administered hypodermically, is absolutely inefficient. The children inevitably die while taking quinin unless use be previously made of intestinal eliminators. The greater number of cures and the rapidity with which they are affected depend evidently on the energetic administration of calomel, castor oil or other laxatives, the use of antiseptics and intestinal injections, stimulants of nutrition, and rigorous hydric diet.

CLINICAL CHARACTERISTICS.

Very frequently the fever reappears owing to some neglect of the dietetic plan during convalescence and again yields under the same therapeutic treatment. The inadequate, defective or tardy treatment, the lack of compliance with any detail of the medical prescriptions, physical weakness on the part of the child to resist the disease, intensity of the toxemia owing to the retention of toxic substance in the higher portion of the intestinal canal, due to the atony of the muscular coat, hereditary tendencies or renal insufficiency, are all circumstances which contribute to aggravate these cases, originate secondary infections, and occasion the fatal end of the disease.

The second type of these fevers comprises the cases of slow course. The persistence of fever constitutes the ruling feature of this group. Together with the febrile symptoms gastrointestinal troubles are developed as well as troubles of the other organs without there being any constant relation between the former and the latter.

The disease as a whole reproduces the clinical characteristics of an incomplete typhoid fever, and it may last from one to four weeks, there being cases of longer duration.

The thermic cycle varies greatly: the type of subcontinuous fever is very common during the first and second day, followed by remissions which become more and more pronounced in the subsequent days. There may be accesses every two days and periods of abatements lasting one, two or three days followed by a new rise in temperature which generally occurs together with an aggravation of the intestinal symptoms. Therapeutic intervention directed against the gastrointestinal states always modifies the course of those cases. At other times a moderate and rather regular remittent fever is observed which lasts for many days without any more symptoms until suddenly febrile paroxysms present themselves which then become complicated with cerebral phenomena and may be followed by death with all symptoms of toxemia. In other little patients the fever maintains its remittent character for many days and then diminishes gradually in an irregular way.

The digestive disorders accompanying the feverish syndrome may vary from the mildest form to the predominance of gastrointestinal localization of certain intensity. The tongue is red and somewhat desquamated or slightly coated; there is vomiting of mucous matter, fetid breath, anorexia and thirst; the stools have a semifluid consistency of greenish yellow color, grumous and mucoid, very foul at first and occasionally like those of dysentery. The urine is turbid, loaded with uric acid, urates and sometimes mucin or albumin. Usually the stools turn yellow and lose their offensive smell.

The visceral infarctions are frequent; the liver is almost always augmented and its consistency may reach that which is observed in cirrhosis. The spleen may also be enlarged, but this is less frequent. This fact may occur at the onset of the disease. Finally there are cases where both viscera are in normal state from the beginning to the end of the disease.

The exploration of the abdomen shows pain and distension at the level of the transverse colon in the ascending and descending colon, these symptoms disappearing later on more or less intense fever remaining as the only manifestation of the pathologic process.

Not unfrequently cases are observed which act in a normal way, and with tendency to constipation, but oily laxatives determine the expulsion of mucosities and the attenuation or temporary disappearance of fever. This result at other times can not be obtained without a change in the alimentation.

The type of enteritis of typhoid form of the ancient writers is recognized when studying some of these pathologic classifications in children under two years of age. In other children the morbid process has the type of the gastrointestinal troubles of the ancient writers, or that of gastric fever, which traditional observation separated from the similar form of typhoid fever and malaria.

The diagnostic study of every fever is one of the most difficult ones that may present themselves in pediatric practice. Before the birth of bacteriology the clinical and epidemiologic criterion served as a base to distinguish general diseases among themselves. Often the diagnosis was left uncertain when it could not be confirmed by means of pathologic anatomy. Bacteriologic discoveries have afterward solved many etiologic problems; but doubtless the negative result and the insufficiency of our knowledge in that respect have contributed to a certain extent to throw more confusion on the etiologic conception of some morbid processes. Besides, modern procedures of investigation and experimental demonstrations have revealed that side by side with the better known specific infections there are others which are not

classified as yet. This has given rise since the notable work of Bouchard, to the doctrine of intestinal auto-infections, by which it is tried to explain at present the nature of certain obscure, incomplete or atypical processes which according to the epidemiologic criterion were systematically included in either of the two great pyrexias, typhoid and malaria, and also in yellow fever in countries like ours. In order, therefore, to properly solve the diagnostic problem we must be more cautious than ever, trying to resort to every possible source of positive information; clinical observation, first, laboratory work afterward and a minute etiologic investigation comprising the patient and the surroundings.

Having thus excluded malaria, grippe or typhoid as origins, disregarding the other processes, local or general, capable of producing fevers of a similar course in children, it may be admitted that the forms of slow course that have been described are, in the same way as those of rapid course, consequences of putrefactions that take place in the intestinal tube. These putrefactions may be caused either by direct introduction of morbid agents with the food or by the increased virulence of the micro-organism habitually living in the intestine in a saprophytic state, due to faults in the dietary or to other external influences. The effects are the same: increased intestinal fermentation, production of toxic element and consecutive autointoxication after their absorption in the circulatory system. The feverish syndrome represents a functional trouble depending on an infection which takes place on the surface of the mucous membrane without leaving a trace of any kind. At other times the infection causes more or less extensive injuries which may be propagated to other organs of the digestive apparatus and to the remainder of the organism.

This way of thinking agrees with the work carried out in recent times by Hayen, Lesage, Thiercelin, Escherich, Baginsky, Booker and many others on the part acted by divers micro-organism in the production of infantile gastroenteritis.

An inspection of medical literature shows that the same doubts have arisen in all parts of the world about the classification of those feverish types, which differ in many respects from all the other groups of defined specific infections.

Kelsh and Kiener, Ferée and Vincent in Algiers have argued against those morbid states described by Sesary under the name of gastrointestinal fevers. Legrain, more recently, has attributed them to the colon bacillus and he affirms that this agent may give rise to a whole series of cases of remittent fevers which offer a scale of seriousness from the simple mild form to the syderant form resembling yellow fever. Manson studied them among "unclassified tropical fevers." In Italy, Tomaselli, Cantani, Fazio and others discussed them many years ago as a *sui generis* infection. Fedé, of Naples, describes it with the name of "gastrointestinal infection of infancy," and it is very common to find allusions to those diverse types of fevers in the medical literature of the United States.

The expression "entero-septic fever" proposed by Dr. Tomás, of Matanzas, has become very usual in Cuba, and it is certainly preferable, as it has the advantage of expressing the location and nature of the pathologic phenomena without making reference to any specific micro-organism.

In conclusion, the feverish process during the infantile period of life is very frequent in the Island of Cuba. In a great number of times fever owes its existence to the same infectious diseases which have been described by observers of other countries. Ignorance of this fact has been one of the causes which have contributed to mislead medical opinion on the nature of infantile pyrexias. As a rule, these pyrexias have a tendency to reveal a similar clinical expression during early stages of life. In other words, there does not always exist a constant relation between the infectious agent and the clinical phenomena exhibited by the patient. Hence the diagnosis is extremely difficult and requires minute and wide information of a clinical, etiologic, epidemiologic and experimental order to reach with more certainty the scientific truth.

But it can not be denied that most of the infantile fevers come from intestinal infection. These fevers which I have classified in two groups, according to their duration, correspond to the same processes that in the ancient nosologic classifications were called acute enteritis or enterocolitis, and which at present are named by some writers infectious gastroenteritis or infectious enterocolitis; also intestinal fevers or intestinal infections. Endogenic or ectogenic infections of the intestinal tract are the ones which give rise to the feverish types already described; the septicemic or rapid and the enteroseptic or slow, according to the predominance of the symptoms of autointoxication of the organism or whether more or less extensive inflamatory lesions on the mucous membrane of the intestine are produced.

The prognosis in these fevers depends on the virulence of the germs producing them and on the amount of resistence opposed to it by the organism of the child; but to a great extent it is secondary to the opportunity and energy of the treatment employed as well as to the experience acquired on infantile diseases.

A CONTRIBUTION TO THE PATHOLOGIC HISTOLOGY OF SYPHILITIC ETHMOIDITIS.

J. L. GOODALE, M.D.
BOSTON.

Among the causes of chronic inflammation of the ethmoid bone syphilis has long been considered to play a prominent part. In the cases, however, which usually come under observation the process is well developed, and it is a rare experience to be able to follow the condition from the beginning. The following case is, therefore, of particular interest, especially in view of the fact that a histologic examination of the anterior portion of the middle turbinate was made at an early stage of the disease.

NARRATION OF CASE.

P. J. B., a man 30 years of age, was referred to me by Dr. H. W. Kilburn, Oct. 25, 1899, with reference to a possible source of irritation in the nose, which might cause inflammation in the conjunctiva of the right eye. Examination showed an enlarged right middle turbinate, the nose and throat being otherwise essentially normal in appearance. The patient's previous history was negative.

The anterior end of the right middle turbinate was snared, and found to exhibit cystic enlargement of the bone. November 1, a portion of the stump remaining was removed with the conchotome. November 16, examination of the right middle turbinate showed an irregular swelling at the margin of the stump which had the appearance of granulation tissue, and which was of such size as to occupy almost the same region as the original anterior extremity. This was removed by the snare. November 21, the granulation tissue had reappeared, and by December 5 had exceeded even the original size of the turbinate. The patient was then put on protoiodid of mercury, one quarter grain, t.i.d. December 19, examination showed the growth to have become smaller, and

exhibiting a cleaner, smoother surface. January 1, iodid of potassium was added to the mercury. The growth continued to diminish in size, and by May 2 was no longer visible. May 22, there was an ozenic odor from the nose, and a portion of dead bone from the region of the right ethmoid was removed. June 19, the region of the right ethmoid showed much irregular retraction and distortion, but there was no odor or discharge. The patient was continued for the next few months on small doses of iodid of sodium. October 1, there was again a polypoid swelling of the right middle turbinate, with purulent discharge, together with a bad odor. Mercury was again administered, in combination with the iodid, and was followed by a disappearance of the polypoid swelling and of the odor. The patient has since that time taken 10 grains of iodid of potassium or sodium, 3 times a day, together with mercury at intervals. There has been no return of the polypoid swelling of the right middle turbinate, and he has been otherwise in excellent health.

Histologic Examination.—The specimen removed Oct. 25, 1899, of the right middle turbinate showed a hemispherical wall of bone, lined on its interior with mucous membrane, and covered externally by swollen erectile tissue and mucous membrane, differing macroscopically in no essential particular from the appearances found in ordinary cystic degeneration of the middle turbinate. The specimen was hardened in Zenker's fluid, and imbedded in paraffin.

Specimens stained with alkaline methylene blue and eosin show, under a low power, the epithelium of the interior and external aspects to consist of flattened pavement cells. In places, the epithelium exhibits an invagination, the walls of which are lined with columnar cells. The epithelial cells are everywhere penetrated with polynuclear leucocytes, particularly in the regions of the invaginations. Below the epithelium there is seen to be a marked proliferation of the connective tissue cells, and of the endothelial cells of the blood vessels. The region immediately below the epithelium contains large numbers of polynuclear leucocytes, which extend downward, though in diminishing numbers, to a point about midway between the epithelium and the periosteum. These are accompanied by lymphoid cells, plasma cells, and a small number of Mastzellen. The mucous glands present no characteristic changes, and no abnormal infiltration of cells in the vicinity. In the submucous region, the most striking changes are seen in the connective tissue. This exhibits a marked proliferation, increasing in intensity, as one advances in the direction of the periosteum. Sections stained with Mallory's triple connective tissue stain show characteristic blue connective tissue fibers to begin a short distance below the mucous membrane, and to increase in density and abundance rapidly. The deeper mucous glands are surrounded on their inferior surface by connective tissue of considerable density. The blood vessels in the regions of the most marked connective tissue proliferation show a thickening of their intima, resulting in a narrowing of their lumen, and giving the characteristic picture of obliterative endarteritis. The periosteum presents a marked proliferation as shown by the closely-packed osteoblasts, and covers irregular prolongations and digitations of the bone. This is chiefly marked on the distal surface of the bone, which in cross section has the appearance of being broken up into numerous irregular islands. The proximal aspect of some of these islands of bone shows but little alteration from the normal, although others are completely surrounded by numerous osteoblasts. Here and there, particularly on the proximal aspect of these islands of bone, osteoclasts are seen, although apparently not more numerous than in middle turbinates of essentially normal character.

In reviewing the description of these appearances we see that the tissue changes consist essentially in a proliferative periostitis, with a new formation of bone in the form of irregular excrescences, in association with a proliferation of the connective tissue in the vicinity and of the endothelial cells of the arteries, leaving in places an obstruction of their lumen. These changes partake of the character of a granulation tumor rather than of a gumma, and are to be referred to the class of syphilitic new growths termed syphiloma.

DIFFERENTIAL DIAGNOSIS.

The differential diagnosis in this case could hardly have been made clinically, previous to the rapid recurrence of the granulation tissue, after each operation. Even then it is not very uncommon, in the writer's experience, for recurrence of granulation tissue to take place after operation, in cases of ethmoiditis, due to influenza. In the case under consideration the prompt effect of anti-syphilitic remedies established the diagnosis beyond question. From the histologic standpoint it is probable that a diagnosis of syphilis could be made with a reasonable degree of certainty. In cases of ethmoiditis following influenza, and in those cases of polypoid enlargement of the middle turbinate, of unknown, but at least of non-syphilitic etiology, we find, to be sure, a proliferation of the periosteum, with a new formation of bone, but by no means such marked changes in the connective tissue or in the arteries.

It is to be hoped that in cases of ethmoiditis of a similar nature investigators will not only bear in mind the possibility of syphilis, from a clinical and therapeutic point of view, but will subject the excised tissue to careful microscopic examination.

Quackery Quarantine.—The citizen has as much need of quarantine against ignorance and quackery in medical practice as he has gained against all forms of contagion.—G. F. Johnston, Pres. Kan. Board of Regis.

Quadruple Pregnancy with Two Ova.—Baudouin describes (*Gaz. Med. de Paris*) a recent delivery at Paris in which one ovum contained three fetuses, two of them forming a sternopagus, all of the female sex, and one of them surviving. After their delivery a second bag of waters ruptured and a stillborn male child followed.

Lectures on the Physician's Relation to the Community.—The students of Harvard Medical School, says the *Boston Medical and Surgical Journal*, have, on their own initiative, arranged for a series of evening lectures to be given by prominent men, not necessarily physicians, on the general topic of the relation of the physician to the community. This action is noteworthy from several points of view. It shows, in the first place, a growing interest among students of medicine in the broader aspects of their professional work and in the responsibilities which it is sure to entail. Such a movement on the part of medical students, popularly supposed already to be overburdened with lectures, could hardly have occurred ten years ago. To those who have watched the development of the last few years, however, it comes as no great surprise. The students are certainly becoming more and more independent in thought, and are standing more in judgment on the work which they are called on to do and on the teachers who direct it. The results have been in every way salutary, both as regards teachers and students. The desire of a large body of students to provide certain lectures for themselves furthermore points toward a definite need, which they are feeling is not supplied them in the regular course. They want, broadly speaking, to learn from men of experience of their future social and ethical relations to the communities in which they may happen to be placed. This is evidence that they receive no such instruction in their ordinary undergraduate work, which, we believe, is the fact. This leads us to speak of a distinct lack in medical education, and that is, the direction of students in their relation to patients and others whom they must later come in contact with in their professional work. No attempt is made to teach the ethics of medicine except by precept and example, a good but not a sufficient method. Students of medicine certainly need instruction in this subject, a fact which the Harvard students have appreciated.

THE DIPLOMA VS. EXAMINATION.

An esteemed correspondent offers in this issue some criticisms on a recent editorial in these columns on the above subject, and asks for reasons for the position we assume. Reduced to a sentence, our critic objects to examination by state boards, and wants the medical college diploma recognized as the only necessary qualification for the right to practice. In other words, he would have us go back to the old conditions. Arguments against this position have been given over and over again in the past in medical societies, in medico-sociologic discussions and in medical journals. It would seem useless to go over these again, or to point out the incorrectness of the claim that instructors are in a better position to judge of the fitness of a man to practice than a company of individuals "armed with a series of stock questions," when by "instructors" are meant the faculties of medical colleges, the large majority of which exist for purely commercial purposes, and by "a company of individuals" is meant a state examining board.

In the main we agree with our correspondent that it would be easier and, possibly, more "in harmony with the economic and centralizing spirit of the time, for a small number to authoritatively investigate and pass on the educational merits of fifty or one hundred institutions of learning occasionally, than to adopt the task of perpetually investigating the qualifications of thousands of individuals." If this body could be a national one, with full authority in all the states, composed only of thoroughly competent and disinterested men, and absolutely secure against all local, external, and political influences, it might be that the problem would be solved. But how are we to select such a competent body, and who is to give them the right "to authoritatively investigate and pass on" the merits of these institutions? There would still remain the question how to dispose of applicants from institutions not in the recognized list, and how to meet the pressure for such recognition. These, perhaps the most embarrassing problems, would still remain unsolved.

The great obstacle in securing satisfactory legislation comes from the fact that such legislation is a function of the state and not of the national legislature. And here we are reminded that the average state legislature is prone to be decidedly too lenient with its own institutions and, if possible, to favor these as against those outside of the state. Further, no state can rightfully deputize a matter involving the health and welfare of its citizens to an indefinite number of irresponsible bodies, such as college faculties, which are outside its limits and in no way subject to its jurisdiction or to that of the national government. A diploma from a few colleges means something, from the majority it means nothing, unless it be that the holder has paid a certain number of dollars into the treasury of the institution that granted it.

No other civilized nation, so far as we know, grants the right to practice on a diploma granted by a private teaching institution, and even Uncle Sam guards his soldiers and sailors, for it is well known that no one can be admitted to the medical corps of the Army, the Navy, or the Public Health and Marine-Hospital Service on the strength of a diploma alone, no matter how high the standard of the college issuing it.

We hardly see that the requirement of a diploma as a prerequisite to examination is a confession of weakness. The diploma is supposed to be an evidence of a certain amount of medical training and clinical instruction and the requirement of this or of some evidence that the applicant has had clinical experience should be insisted on. Many states, however, do not require a diploma, depending entirely on examination. Our correspondent's reference to "A central examining board and its associate committees" is of local import only, as we presume he refers to the pending legislation in Illinois.

We recognize as a fact that but few of our state examining and licensing boards are constituted as they should be; that written and oral examinations by means of questions and answers, and without practical clinical demonstrations are decidedly unsatisfactory, and that for an already licensed physician to have to pass an examination when he chooses to move to another part of his own country, if this should happen to be another state, is worse than outrageous. But, in spite of all this, we can not think of going back and of giving to commercially controlled medical colleges the right to say how much or how little a man or woman must know before entering on the responsible duties of a practicing physician.

The question of medical education and with it that of protecting the public from incompetent practitioners, charlatans and impostors, is one for our profession to solve and, as stated above, the question is seriously involved from the fact that we have to recognize fifty different legislating bodies. For years we have been improving, the standard has been gradually raised, and we can not afford to go back now. We must, however, recognize the necessity for meeting the present unsatisfactory conditions, especially that of granting a man the right to practice all over his own country if he has the right to practice in any part of it.

CHLOROMA, OR GREEN TUMORS.

There are few parts of the human body that have received more attention from investigators and clinicians during recent years than the lymphoid structures —spleen, lymph glands and bone marrow. The numerous contributions relating to splenic anemia indicate a growing interest in the disease as well as a general spread of a knowledge of its clinical and anatomic characteristics. A commendable, critical spirit has arisen with regard to Hodgkin's disease, and cases are repeatedly submitted to laborious inquiry to determine their tuberculous or non-tuberculous nature. The researches by Warthin and others on the hemolymph glands, the study of the hematopoietic structures in acute infections, and the increasing importance of these organs in the production of immunity have greatly advanced the work in this field. In this field of diseases of the blood-forming organs there is much to attract the clinician and to stimulate him to careful and complete observations of the many interesting forms of disease that here may meet him.

Although it may be determined at some future time that chloroma is simply a rare form of other and better known processes of disease, the recent accounts of two cases by Rosenblath and Risel,[1] together with their summary of the literature, leave a strong impression that this condition will always command a separate place on account of the clinical features. Notwithstanding that the first report dealing with these grass-green, yellowish or grayish-green tumors was made nearly one hundred years ago, only about 20 cases have been recorded since. In most of the cases double or unilateral exophthalmus is one of the earliest symptoms and naturally has frequently led to the consultation of ophthalmologists. It is caused by development behind the eyeball of tumors which soon become palpable. Exophthalmic goiter has been suspected or diagnosed in a number of cases. Tumors develop elsewhere also, as in both pseudoleukemia and leukemia, but with a marked predilection for the periosteum, especially of the skull bones; occasionally the long bones, sternum or vertebræ are affected. In this feature of chloroma there will be seen a close resemblance to those other rare tumors of bone, the multiple myelomas, which are also allied to leukemia and pseudoleukemia. In many cases of chloroma a hemorrhagic diathesis has been observed, and in a few cases changes have been found in the blood similar to those of acute leukemia.

The disease runs a short course and terminates fatally. In some of the cases a green coloring material appeared in the urine. In the two cases considered by Rosenblath and Risel the so-called Bence-Jones reaction of the urine for albumoses was absent. The peculiar color of the growths is not appreciable unless portions of the more accessible tumors are removed for examination; in some instances operations, such as evisceration of the eyeball, have revealed this striking characteristic.

Various theories have been advanced to explain the pigmentation of the newly-formed tissue, but as yet no satisfactory solution of this question has been reached; the theory of metamorphosed pigments from the blood, however, has numerous points in its favor. It is to be regretted that there are no accounts of bacteriologic investigation of the cases reported by Rosenblath and Risel for this aspect of chloroma merits thorough examination. The attention of the profession generally should be directed not only toward the recognition of these cases, but also toward securing complete investigations.

UNDERGROUND TRANSIT AND PUBLIC HEALTH.

The question of transportation in our great cities is one that is agitating public opinion and becoming more or less an issue in local politics. The inconveniences of obsolete systems not progressive *pari passu* with the growth and needs of the cities call more and more for better facilities, especially in view of the modern tendency to concentration of population and expansion of municipalities. The inconvenience, however, of permanent surface railway tracks in the business centers is such that some substitute is constantly being advocated. Surface railroads are going out of date in some of our larger cities and elevated and underground transportation are being advocated. New sanitary questions will be raised by these changes and it is worth while to make some inquiry for the benefit of the public as to all the possible dangers.

The subject is taken up by Dr. Louis C. Parkes in the Public Health article of the *London Practitioner* for February. He points out the dangers to health from the confined air in subways. He shows that the amount of carbonic acid gas is increased in the atmosphere of the railway tubes and that the sanitation of the Central London Railway underground line, as shown by most recent investigations, is very bad, especially at the times when the traffic is greatest. Air of the carriages has been found to contain as much as 15 to 25 parts of carbonic acid per 10,000, or four or five times as much as in the atmosphere. While this is unquestionably deleterious to health, even though breathed for a comparatively short time, there are still other dangers to which he calls attention in subway traveling, such as the danger in the warm summer and the cold winter months alike of bodily chilling. In hot weather the traveler changes suddenly from a warm street to a much colder atmosphere and in winter the reverse happens. Then, again, the air is so confined that it can not purify itself of carbonic acid gas, and also contains a large amount of organic material and the dangers of contagion, tuberculous infection, etc., are vastly increased. It is impossible to prevent overcrowding of these cars at certain periods of the day, and this greatly aggravates the conditions. He also speaks of the tendency of large numbers of people living adjacent to these routes and traveling by tube to their working places and back again to their

homes, living their whole lives in an artificial atmosphere. What can be expected, he asks, from such a mode of existence but physical degeneration and lowering of the national health?

While this is at present more especially a London problem and one hardly yet applicable to American conditions, except possibly in New York City, it is still one to which, in view of future possibilities, we can give our careful attention. He thinks there is danger of the passive and little-assertive Londoner being rushed into costly and ill-digested schemes of multiple "tube" transit. It is a pretty generally acknowledged fact that in matters of public grievance the English are better "kickers" than the Americans, and we would do well to take some of this warning in this country where underground transit projects are being considered. The question of rapid transit in our municipalities is very far from being settled. We should utilize the experience of older countries where methods like the underground railways, etc., have been long in use and have afforded chances for observation of their effects.

MICHIGAN BOARD UPHELD.

It is well known to our readers that the Michigan State Board of Registration has had trouble almost from the beginning with a certain class of practitioners, and more especially certain of the graduates of the Armstrong diploma mills of Chicago. The strife has been carried up through the courts until it finally reached the highest tribunal in the land, and a decision has only recently been handed down. This was delivered by Judge Brewer and not only establishes a precedent, but fixes the status and authority of such medical boards, at least in certain particulars. The judge says in part: "The power of the state to make regulations providing for determining the qualifications for those engaged in the practice of medicine and punishing those who attempt to engage therein in defiance of such statutory provision, is not open to question." The state courts are the tribunals in which the question of the constitutionality of the acts as regards the state constitution is to be decided, and in this decision it is said that there is no decision known in the federal constitution forbidding a state from giving to a tribunal, whether it be called a court or a board of registration, the final determination of a legal question. Certain minor points which have been brought up by the plaintiffs were also settled, and the decision as a whole is a valuable one as establishing jurisdiction of registration boards and the legality of medical practice acts.

THE THERAPEUTICS OF THE CACODYLATES.

Within the last few years much has been published in regard to certain special arsenical compounds and their therapeutic value. These compounds, cacodylates, were found to be practically non-toxic in large doses, and it was claimed that they produce many of the therapeutic results of the basal element. Some recent investigators, however, have thrown discredit on the therapeutic efficacy of these drugs, claiming that they are practically inert in the system. They have, nevertheless, been found to produce certain symptoms, not those of ordinary arsenical preparations, which are of disadvantage. More recently, to obviate these latter disadvantages, still another organic compound of arsenic, disodic methyl arsenate, has been introduced and given the name of arrhenal, and has formed the subject of a number of clinical contributions. At a meeting of the Edinburgh Medico-Chirurgical Society, January 21, the president, Sir Thomas R. Fraser, reviewed the subject, calling attention to the fact that the efficacy of arrhenal had been combated, more especially its efficacy in malarial affections. He reported cases in his own practice where it had been given as a substitute for the ordinary arsenical preparations, but without the results that might have been expected were its effects those of arsenic itself. He also made examinations in order to determine why these failures occurred, as to the chemical conditions, using tests of extreme delicacy and found no evidence that arsenic was retained in the body after the administration of the drug. As in the case of the cacodylates, according to later reports, it passes unaltered. The general results of Fraser's observation were that arrhenal was practically an inert substance, that it can not produce either the pharmacologic action or the toxic effects of the arsenic ion and that, therefore, it is incapable of exerting remedial or therapeutic effects of the commonly used compounds of this substance. It seems now probable that both the cacodylates and this more recent substitute will pass into disuse unless some special properties not those of arsenic are absolutely determined. The enthusiasm with which these were at first received appears to have been unwarranted by fuller experience and may be taken as another instance of ill-judged medical faith in a remedy which is often one of the misfortunes of the profession.

Medical News.

CALIFORNIA.

Lehman Acquitted.—Dr. Charles A. Lehman, San Diego, who has been on trial charged with practicing medicine without a license, was acquitted February 19.

Will Not Change Law.—The Assembly Committee on Public Health and Quarantine has reported against the bill changing the law regulating the State Board of Medical Examiners, and providing that medical graduates must be given certificates to practice without further examination.

Plague Stamped Out.—Governor Pardee has transmitted to the legislature a message from the surgeon-general of the United States Public Health and Marine-Hospital Service, announcing that no plague has been discovered in San Francisco since Dec. 11, 1902; that searching inspections are being made daily in Chinatown and that no infected rat has been found since Dec. 8, 1902.

Births and Deaths in San Francisco.—The deaths in San Francisco during January numbered 783, equivalent to an annual death-rate of 21.44 per 1,000. The death rate for the corresponding period of 1902 was 24.96. The births registered were 544, equivalent to an annual rate of 15.91 per 1,000. Tuberculosis caused 125 deaths; heart disease, 87; pneumonia, 85; nephritis, 47; and violence, 71.

Cancer Specialist Held Responsible.—As a result of the coroner's inquest in the case of a patient under the care of S. R. Chamley, an advertising cancer specialist of San Francisco, the jury found that deceased came to her death from hemorrhage from an operative wound in the breast, through lack of knowledge of the attending physician, Dr. S. R. Chamley, and further found him responsible for her death. It also

recommended that Dr. Chamley's license be revoked for falsely certifying to the board of health as to the cause of death.

COLORADO.

Hospital Incorporated.—The Fairmount General Hospital Association has been incorporated at Pueblo by Drs. Thomas A. Stoddard, Ferdinand G. Mohlau, Charles O. Rice, and others.

Farm for Use of Consumptives.—David Brothers has given an improved farm of 36 acres, valued at $20,000, to the Y. M. C. A. of Colorado, to be used in connection with its proposed sanatorium for consumptives. A large number of tents will be erected as domiciles for the patients, who will be expected to work on the farm in part payment of their board and lodging.

Medical Bill Amended.—The Sanford bill, which passed the house February 7, was delayed when it reached the senate, which body amended it. One of the amendments provides for a state board of medical examiners, to be composed of 12 members, six of whom are regulars, two homeopaths, two eclectics and two osteopaths. Applicants are to be examined by that fraction of the board representing their desired line of practice.

State Board of Health Reorganized.—The board met at Denver, February 19, and reorganized, electing Dr. Josiah N. Hall, Denver, president; Dr. William H. Davis, Denver, vice-president; Dr. Claude E. Cooper, Denver, secretary, and Dr. Frank N. Carrier, Canon City, treasurer. The governor has appointed Drs. William H. Davis, Denver; Frank N. Carrier, Canon City, and Edward A. Mattoon, Salida, new members of the board.

DELAWARE.

Personal.—Dr. Pietro A. M. Rovith has succeeded Dr. John C. Fahey as physician of the Italian Mutual Beneficial Society of Wilmington.

Physician as Senator.—Newly-elected Senator Louis Heister Ball, Faulkland, who has previously served his state as treasurer, and as member of congress, is a practicing physician, and was graduated from the University of Pennsylvania in 1885.

Reception to Dr. Flexner.—Dr. Joseph P. Pyle, Wilmington, gave a dinner and reception to the physicians of Wilmington, February 3, at which Dr. Simon Flexner of Philadelphia was the guest of honor and delivered an address on the serum-therapy of diphtheria and typhoid fever.

DISTRICT OF COLUMBIA.

Personal.—Drs. John T. Dunn and W. Robert Perkins, both of Washington, have become resident physicians of Emergency Hospital, as the result of a competitive examination.

University of Vermont Alumni.—The fifth annual dinner of the Alumni Association of the University of Vermont was held February 27. Dr. A. F. A. King of Washington was elected president.

Health of the District.—Report of the health officer for the week ended February 21 shows the total number of deaths to have been 135, of which 74 were white, 61 colored, number of births 76, 45 white, 31 colored. At the close of the week there were under treatment 101 cases of typhoid fever, 12 of scarlet fever, 6 of diphtheria, 8 of smallpox.

New Hospital and School Opened.—The new hospital and building for the department of medicine and dentistry of the Columbian University were formally opened February 28. The new hospital contains private rooms and medical and surgical wards, with three operating rooms and a dispensary. The new medical building has four lecture halls, each seating from 200 to 350, large laboratories for chemistry, pharmacy, histology, physiology, bacteriology, pathology and anatomy, with recitation rooms, museum, library, reading rooms, etc.

To Prevent Epidemics.—Representative Smith of Illinois has introduced a bill in the house to prevent the spread of communicable diseases in the district. The bill provides that every person in charge of any patient who is suffering from measles, whooping cough, chicken-pox or epidemic cerebro-spinal meningitis, immediately after becoming aware of the existence of such disease, shall send to the health officer of the district a certificate, stating the name of the disease; the name, age, sex and color of the patient; the school which he or she has attended, if any, and the name of the physician, if any, in attendance on the patient; and designating the place in which the patient can be found. If the patient recover, the person in charge must send to the district health officer a certificate to that effect. But no person shall certify that a patient has recovered until he is free from danger of communicating the disease to other persons. Every physician attending any patient suffering from communicable disease, immediately after discovering the nature of the disease, must notify the person in charge of the patient of its nature and that the person in charge is required by law to report the case to the district health officer. The bill makes it unlawful for any person in the district suffering from a communicable disease or from symptoms which so resemble those of a communicable disease that they can not be distinguished therefrom with reasonable certainty, or for any physician attending or examining any such patient, or for any person in charge of such patient, to do any act reasonably likely to cause the spread of such disease, or to omit the performance of any act reasonably likely to prevent the spread of such disease. Any person who violates, or aids or assists in the violation of any of the provisions of the proposed act is made liable to a fine of $100 or to imprisonment in the workhouse for thirty days.

ILLINOIS.

Fire at Marion.—A fire which broke out at Marion, February 19, destroyed the offices of Drs. George W. Evans and Griffin Baker, Jr.

To Clear Title.—The University of Illinois has transferred to the College of Physicians and Surgeons, Chicago, the property now used as the medical department of the university. The transfer is made for technical reasons, to clear title.

Veterans Are Dying.—Statistics prepared by the adjutant-general of the department of Illinois, Grand Army of the Republic, show that in the year just closed there were 702 deaths among the 21,725 members in Illinois, a death rate of 30.8 per 1,000.

Personal.—Dr. Samuel M. Wylie, Paxton, has been elected to fellowship in the German Surgical Society.——Dr. James A. Marshall, Pontiac, declares his intention of resisting discharge as physician of the state reformatory at Pontiac, on the ground that the institution is under civil service supervision, and that no employe can be discharged for political reasons.

Hospital to Celebrate Silver Jubilee.—St. Francis Hospital, Peoria, is making extensive preparations for the celebration of its twenty-fifth anniversary, March 20, 21 and 22. In 1878 a building which cost about $10,000 was the home of the hospital. In October, 1901, the new hospital was opened, which cost $125,000. The institution also has branches at Bloomington, Ill., Menominee, and Marquette, Mich.

Chicago.

Widow Sues Physician.—Mrs. Mary Kerwin has sued Dr. Thomas J. Balhatchet on the charge of larceny as bailee, claiming that he withheld $1,023 of insurance money on her husband. Dr. Balhatchet claims that he attended the plaintiff's husband, receiving in lieu of fees for medical service, promissory notes, secured by the insurance policy. He characterizes the suit as an attempt to extort money.

Personal.—Dr. Casey A. Wood has returned from a stay of several weeks in the east.——Dr. Seward P. Gibbs was struck by a cable car, February 19, and seriously injured.——Dr. Maurice F. Doty has been elected president of the Referendum League.——Dr. George E. Cooke has moved to Arlington, Ky. ——Dr. Augustus L. Craig, who was recently robbed of a suit case containing valuable securities, was so fortunate as to have them recovered by the Kansas City police.

Record-Breaking Mortality.—The 713 deaths recorded during the week ended February 28, represent an annual mortality rate per 1,000 of 19.73; and the 2,570 deaths in the month give an annual death rate of 18.30 per 1,000. These figures break all records for a week in February, and the rate for the month is the highest recorded since 1882. As compared with February, 1902, however, there were 16.2 per cent. more deaths over 60 years of age and 4.6 per cent. fewer under 5 years of age.

IOWA.

The Board's Work.—During 1902 the State Board of Medical Examiners issued 538 certificates, 300 of which were issued to osteopaths. Of the remainder 211 were regulars, 24 homeopaths and 3 eclectics.

Personal.—Dr. George Kessel, Cresco, was thrown from his buggy, February 22, fracturing his left arm near the wrist and breaking his nose.——Dr. Lysle Reppert, Muscatine, has returned after a year of study in Europe.

Golden Weddings.—Dr. and Mrs. Benjamin F. Keables, Pella, celebrated the fiftieth anniversary of their marriage, February 24.——On New Year's evening Dr. and Mrs. Joseph

L. Powers, Reinbeck, commemorated their semi-centenary of married life.

Itinerant Physician Indicted.—Dr. Edwin E. Rohrabaugh, an itinerant rupture specialist of Chicago, arrested at Des Moines on the charge of practicing without a permit from the State Board of Health, was found guilty, gave bond of $1,000 to appear for sentence when called on, and left the city.

Faculty Member Resigns.—Dr. Charles Henry Hoffman, professor of histology and bacteriology in the medical department of Drake University, Des Moines, has resigned because he refused to give his real name. For the same reason he resigned as censor of the Des Moines Pathological Society. He admits that he is bound by honor not to reveal his true name until he has permission to do so.

MARYLAND.

Minute Damages.—The suit of Mr. R. E. Lee Bosley of Towson, former sanitary officer, against Dr. R. C. Massenburg, for $10,000 damages, resulted in a verdict of one cent.

Smallpox at Chestertown.—There are three cases of smallpox at Chestertown. Dr. G. W. C. Rohrer of the City Hospital has been engaged to attend them at $10 per day, and a house is being erected near the pesthouse for his residence.

Physician Fined for Assault.—At Hagerstown, February 24, a fine of $200 and costs was imposed on Dr. P. Elwood Stigers, Hancock, for assault on a dentist of the same place. The court said it was a most grievous offense, and that only the numerous appeals for clemency saved the accused from imprisonment.

For New Epileptic Ward.—Plans for the new epileptic ward at Maryland Hospital for the Insane (No. 2) are being prepared. The cost will be $25,000. It will be detached from the other buildings, but will conform to them in style. The dormitory on the second floor will be 21 by 157 feet, and will accommodate about 90 patients. There will be six private rooms in each wing, and on the second floor will be a sun parlor 20 by 33 feet.

New Hospital for Eastern Shore.—The plans have been completed for a new hospital at Cambridge. Of the $40,000 required for the purchase of site and building, Mr. John E. Hurst, Baltimore, has contributed $15,000, the state and Cambridge each $5,000. The site will be a bluff, the highest point in the town. The building will be of brick, in colonial style, 136 feet long, and varying from 51 feet deep at the center to 36 feet at the wings. There will be a basement and three stories and accommodations for 35 patients. The local staff consists of Drs. Brice W. Goldsborough, John Mace, Guy Steele, and Eldridge Wolff; the surgeons are Drs. Nathan R. Gorter and Thomas S. Cullen, Baltimore, and the oculists are Drs. Herbert Harlan and Henry O. Reik, Baltimore.

Baltimore.

Personal.—Drs. Frank D. Gavin and Thomas S. Cullen have returned from a pleasure trip to Jamaica.

The Week's Deaths.—The mortality was nearly normal last week, the death rate being 19.90 per 1,000 per annum for the whole population. Pneumonia caused 42 of the 212 deaths, bronchitis 11, grip 7, and measles 4.

Tuberculosis Mortality.—The statistics of the Tuberculosis Commission show that the death rate in Baltimore is nearly twice that of the state in the cases of whites, and that the mortality among negroes is twice as great.

Abortionist Sentenced.—Dr. William B. Hawkins, whose conviction of manslaughter by criminal operation was mentioned last week, has been sentenced to 10 years in the penitentiary, the maximum penalty. His lawyers have appealed the case.

Offer of Hospital Site Refused.—A recent offer of a piece of ground of 40 to 50 acres with a large three-story house on it, large enough for 50 beds, to be used for a children's country hospital, has been declined by the authorities of the Robert Garrett Children's Hospital, who have provision in this respect. It has, therefore, been offered to Washington, to which it is nearer than to Baltimore.

Dispensary Report.—The forty-ninth annual report of the Northeastern Dispensary shows that 9,588 persons attended during the year; 5,701 white, 3,887 colored. The appropriation of $1,500 by the state and the contract with the city have put the institution in a good financial footing, while the election of a board of lady managers has added much to its efficiency. Dr. Arthur Wegefarth is president.

MASSACHUSETTS.

Boston's mortality rate has been exceptionally low for the last few weeks. During January there was a good deal of influenza, but the cases were generally of a mild type and not often preliminary to pneumonia, as in some epidemics. Early in February even this mild epidemic abated.

Memorial Infants' Hospital.—A gift of $76,000 to establish an infants' hospital as an adjunct to the Harvard Medical School, is announced; $60,000 more is promised, and the entire gift will be a memorial to Thomas Morgan Rotch, class of '01, Harvard. The site will be adjacent to the medical school, which will be built in the Longwood section of Boston.

The New Harvard Medical School.—Work will be commenced on the new buildings for Harvard Medical School, in the near future. They will occupy a 26-acre lot in the Back Bay Fens. Seven buildings will be erected; five for the medical school, one for the dental school and one for a power house. They will cost more than $2,000,000, and are expected to be ready for occupancy in 1904.

Foot and Mouth Disease.—This disease has again gained a foothold in Massachusetts. A large district of the state has been strictly quarantined and most vigorous efforts are being made to stamp the disease out. Believing that stray cats and dogs are carrying the disease, all such visiting by these animals within that district is forbidden. Pigeons are also suspected by Dr. Salmon of being carriers of the virus, but inasmuch as the virus is submicroscopic it is difficult to prove these suspicions. Few, if any, cases of the disease in children have occurred in the state, which fact accords with the general experience that the disease is only rarely transmitted from animals to men.

Meetings Successful.—The meetings held at the Boston Medical Library this winter have been a great success. In place of the usual dozen or twenty men, the physicians of Boston and vicinity have assembled by the hundred. Dr. William T. Councilman has presided, and the committee have provided a series of excellent papers. At the last meeting, February 23, Dr. Townsend demonstrated that his method for pouring off the upper quarter of a quart of milk which has stood 8 hours yields cream of a uniform percentage of about 10 per cent. fat. Papers were also read on "An Analysis of 117 Specimens of Mother's Milk," "Foot and Mouth Disease," and a lantern slide lecture was given on "Congenital Hip Disease," by Dr. Bradford. The so-called bloodless method was fully explained, and its limitations pointed out. A photograph was shown of a child treated successfully by this method by Dr. Dam at the Boston Children's Hospital several years ago.

MICHIGAN.

Medical Law Sustained.—The United States Supreme Court has sustained the validity of the Michigan law regulating the practice of medicine, affirming the decision of the Supreme Court of Michigan in the case of August G. Reetze, who attacked the validity of the law.

January Mortality.—There were 2,856 deaths reported during January, corresponding to a death rate of 13.5 per 1,000 population per annum. This is 190 more than that registered for the preceding month, and 32 more than the number registered for January, 1902. There were 550 deaths of infants under 1 year, and 906 deaths of persons aged over 65. Tuberculosis caused 195 deaths; typhoid fever, 48; diphtheria, 58; scarlet fever, 36; measles, 13; whooping cough, 40; pneumonia, 382; influenza, 39; cancer, 140; accidents and violence, 126, and smallpox, 7.

Mortality for 1902.—The total number of deaths registered in the state during 1902 was 30,962, corresponding to a death rate of 12.6 per 1,000. For the year 1901 the number of deaths registered was 33,848, and the death rate was 14.0. There were 2,886 fewer deaths registered for 1902 than for the preceding year. At certain important ages, deaths were proportioned as follows: Infants under 1 year of age, 5,754, or 18.6 per cent.; children aged 1 to 4 years, both inclusive, 2,214, or 7.2 per cent., and persons over 65 years, 9,081, or 29.3 per cent. These ratios were substantially the same as for the preceding year. The total number of deaths from certain important causes during the year 1902 was as follows: Tuberculosis of lungs, 2,030, a decrease of 58 from 1901; other forms of tuberculosis, 323, a decrease of 10; typhoid fever, 592, a decrease of 43; diphtheria, 500, an increase of 2; scarlet fever, 261, a decrease of 25; measles, 229, an increase of 156; whooping cough, 290, an increase of 136; pneumonia, 2,907, a decrease of 86; diarrhea and enteritis, under 2 years, 1,350, a decrease of

320; meningitis of all forms, except traumatic and tuberculous, 496, a decrease of 37; influenza, 373, a decrease of 881; puerperal septicæmia, 168, a decrease of 15; cancer, 1,441, a decrease of 2, which may be rather remarkable as perhaps marking a turning point in what has heretofore been a progressive increase of this disease; accidents and violence, 1,951, a decrease of 87.

NEW YORK.

Sale of Adulterated Milk.—The senate has passed a bill providing that the sale of each can of adulterated milk shall constitute a distinct violation of the law.

State Medical Inspector.—A bill has been introduced into the senate providing for the appointment of a state medical inspector at a salary of $5,000 a year, to be appointed by the State Commission in Lunacy, and whose duty it shall be to examine patients and hospitals for the insane.

Typhoid at Ithaca.—During the past week there have been 15 or 20 new cases daily, and the total number of deaths among the students at Cornell has reached 17. Many of the new cases seem to be the result of secondary infection. The local board of health adopted a resolution making it a misdemeanor for any one to drink, or serve to others, unboiled water supplied from the local water company's system.

Personal.—Dr. George K. Meynen, Jamaica, has been appointed chief surgeon of the Long Island Railroad, vice Dr. J. Frank Valentine, deceased.——Dr. Julius F. Wingenbach, Utica, has been made surgeon of the Twenty-eighth Separate Company, N. G., N. Y., vice Dr. William A. Burgess, removed to Cheyenne, Wyo.——Dr. Albert H. Brundage, Brooklyn, has been elected president of the New York State Board of Pharmacy.

Registration of Nurses.—According to a bill introduced by the New York State Nurses' Association, no one is to be styled or known as a registered nurse, or use the abbreviation "R.N." who does not hold a diploma from a training school for nurses connected with a hospital giving a course of at least two years, and who is not registered by the regents of the University of the State of New York. The regents are to appoint, annually, a board of five examiners.

Pure Drug Bill.—A bill, having some peculiar provisions, has been introduced into the legislature by Assemblyman Bostwick, and it has already developed a strong opposition. It is aimed at patent medicine companies, but other drug dealers suffer as well. It compels the labeling of all medicines and drugs, showing what their ingredients are and proof of purity. The label must also state at what time the drug deteriorates and the date when it was put up. Mr. Bostwick now admits that the bill is not as good as he at first thought, but insists that the provision that no druggist shall substitute one drug for another without the knowledge and consent of the buyer should be enacted into law.

New York City.

Lebanon Hospital.—The tenth anniversary of Lebanon Hospital, in the Borough of the Bronx, was celebrated with appropriate ceremonies, February 22.

Columbus Hospital Extension.—This hospital has purchased, in the rear of the present building, three three-story dwellings, which are to be converted into an extension for the institution.

Bellevue Hospital.—The much-needed building for Bellevue Hospital is not long to be delayed, for the first appropriation of $75,000 for the preliminary work has been made, and it is stated that the cost of the new hospital will reach $3,000,000. A new building is also to be built for Fordham Hospital at a cost of $500,000.

Child Labor.—There has been so much evasion of the present laws regarding child labor that a bill has been introduced into the legislature, which prohibits the employment of children under 16 years old in certain dangerous occupations, requires children between the ages of 12 and 14 to attend school throughout the school year, and makes it necessary to produce the certificate of birth, instead of the parents' affidavit of age, before a certificate of employment can be granted to children under the age of 16.

Personal.—Dr. S. Oakley Vanderpoel, medical director of the New York Life Insurance Company, is taking a trip to the Orient, via San Francisco.——Dr. John A. McCorkle, Brooklyn, has been elected president of the Long Island College Hospital. In honor of Dr. McCorkle, nearly a hundred of his colleagues gave him a dinner, February 14.——The reappointment of Dr. A. H. Doty as health officer of the port of New York has been confirmed by the senate.——Dr. Farquhar Ferguson has been transferred from visiting to consulting physician of the Columbus Hospital; Dr. Frederick C. Keller has been appointed attending physician, and Dr. Henry Hazen, attending physician in diseases of children.

PENNSYLVANIA.

Action Against Smallpox.—To stamp out the smallpox epidemic in Bristol, Pa., the mill owners have contributed $5,000 to be used by the board of health. A special hospital is to be erected, and a house-to-house canvass is to be made by vaccine physicians.

A Legislative Visitation.—Members of the house of representatives committee on appropriations, to the number of a score or more, recently spent several days in Philadelphia on a tour of inspection to the institutions, including many hospitals, which have applied for state aid.

Makes Plea for Poor Consumptives.—Dr. Lawrence F. Flick, Philadelphia, was given a hearing by the house of representatives in his advocacy of an appropriation of $300,000 to the Free Hospital for Poor Consumptives. Of such an appropriation, $200,000 would be used to extend the White Haven Sanitarium by an addition of 200 beds; $50,000 for intermediate places to treat patients not well enough to go to White Haveu, and $50,000 for dispensaries in first and second-class cities for the treatment of walking cases.

To Raise Standard of Preliminary Education.—A bill introduced into the legislature seeks to raise the standard of education preliminary to a medical course. The bill requires from candidates for license to practice medicine a diploma of graduation from a reputable college or university, or a diploma of graduation after a four years' course at a state normal, a high school or academy, or a certificate of having passed the examinations for admission to the freshman class of a reputable literary or scientific college or university. The bill provides that, after Jan. 1, 1907, applicants for license must furnish proof that they have pursued the study of medicine for four years, for at least eight months in each year, in four different calendar years, in some legally incorporated reputable medical college.

Philadelphia.

The Children's Hospital.—This institution, a new structure forming a part of the Philadelphia Hospital, has been completed for a few months, but has very recently been equipped and occupied by some 60 inmates from different departments of the institution. Room is provided for 50 more patients.

Personal.—Dr. James Tyson, professor of the theory and practice of medicine in the medical college of the University of Pennsylvania, has been appointed a visiting physician to the Pennsylvania Hospital, the place made vacant by the death of Dr. Frederick A. Packard. Dr. Tyson resigned as visiting physician to the Philadelphia Hospital, and the place has been filled by the appointment of his son, Dr. T. Mellor Tyson.

"Med-Chi" Troubles.—Contractors refuse to make proposals for the repair of Medico-Chirurgical Hospital, recently damaged by a boiler explosion, asserting that, owing to the peculiar nature of the damage, no reliable estimate can be made. The work of repairing will likely be done by the day. Some liberal contributions towards the expense of repairing have been made, but donations are far short of the necessary amount. The Baldwin Locomotive Works Company has donated $5,000 for the maintenance of a free bed.

Deaths and Disease.—For the week ended February 28 there were 12 more new cases of smallpox, 7 of typhoid fever, 1 of diphtheria, and 15 of scarlet fever than for the previous week. From all causes there were 639 deaths, an increase of 57 over the previous week, 47 more than for the corresponding week of last year, and 101 more than for the corresponding week of 1901. Besides the prevalence of the contagious diseases mentioned, affections of the respiratory tract, influenza, bronchitis and pneumonia claim many victims.

The Carnegie Gift Secured.—Andrew Carnegie's gift of $50,000 towards a commodious library for the College of Physicians is assured, as the additional $50,000 which it was stipulated should be raised by the college before his gift was available, has virtually been pledged. An important question to be determined by the college now arises, namely: Whether to increase the height of the present structure or to purchase a new site and erect thereon an entire new building? The latter plan, favored by many of the fellows, would necessitate the raising of a large additional sum.

GENERAL.

X-Rays for Hodgkin's Disease.—A case of lymphadenoma treated by *x*-rays with marked improvement at the University of Colorado Hospital at Boulder suggests the value of further investigations along this line.

Actors' Tuberculosis Sanatorium.—It is said by one of their number that 50 per cent. or more of actors die of tuberculosis. A project is under way to establish in Colorado or New Mexico a sanatorium where actors affected with this disease may find a home and treatment.

Address on Ophthalmology at New Orleans.—Dr. W. Uhthoff, professor of ophthalmology in the University of Breslau, and one of the best known authorities on the pathology and bacteriology of the eye, will give an address before the Section on Ophthalmology of the American Medical Association at New Orleans in May.

Whiting Caught.—Word has been received that Whiting, who has been representing himself to be an agent of THE JOURNAL and the American Medical Association, has been apprehended and is held by the police authorities of Jamestown, N. Y. Physicians in that state who have been defrauded by this individual should at once enter complaints with the chief of police of Jamestown, and physicians in Pennsylvania should communicate with the chief of police of Reading.

The Samuel D. Gross Prize.—The Philadelphia Academy of Surgery announces that this prize of $1,200 will be awarded Jan. 1, 1905, to the writer of the best original essay, illustrative of some subject in surgical pathology or surgical practice, founded on original investigations, the candidates for the prize to be American citizens. The essays should be sent to the "Trustees of the Samuel D. Gross Prize of the Philadelphia Academy of Surgery, care of the College of Physicians, 219 South Thirteenth street, Philadelphia," of whom further particulars may be had.

New Board of Medical Examiners in Hawaii.—Some time ago a board was appointed by the acting treasurer, and later this appointment was called illegal. As mentioned at that time in THE JOURNAL, the physicians whose licenses were thereby invalidated began suit to prevent their re-examination being required. This suit was never brought to trial, and the question arose as to where the appointing power rested. As the result of a recent conference it was decided that the governor should appoint this board of examiners, which he has accordingly done. A number of physicians are waiting examination.

CANADA.

McGill's President Honored.—Dr. William Peterson, president of McGill University, Montreal, had conferred on him the degree of doctor of laws, at Philadelphia, February 21, by the University of Pennsylvania, the occasion being the celebration of Washington's birthday.

An anti-cigarette deputation recently waited on Premier Laurier at Ottawa and presented a largely signed petition praying for the absolute prohibition of the manufacture, importation and sale of cigarettes. The premier has promised consideration on behalf of himself and colleagues.

Manitoba's Health for 1902.—There was no fatal form or epidemic of infectious or contagious diseases in Manitoba in 1902, although there were a number of cases of smallpox in the early part of the year. There were many cases of typhoid fever and the usual number of cases of diphtheria.

British Columbia Quarantining Against the State of Washington.—Owing to laxity of quarantine regulations at Blaine, Wash., where many cases of smallpox exist, the British Columbia authorities have increased the number of special officers assisting Dr. Kendall in preventing any one coming across the line into the province.

Cost of Maintenance in Toronto Hospitals.—The total cost of maintenance in the leading five hospitals of Toronto last year was as follows: General, $85,841.34; Western, $15,504.71; St. Michael's, $39,224.19; Grace, $23,021.14; Sick Children's, $35,000. The cost per patient per day was: General, $0.935; Western, $0.625; St. Michael's, $0.60; Grace, $0.77; Sick Children's, $0.88.

New Maternity Ward for Victoria, B. C., Hospital.—An early start will be made in the erection of a new maternity ward to the Provincial Royal Jubilee Hospital. Lord Strathcona has written the hospital authorities consenting that his donation of $5,000 to the hospital may take that disposition. The total number of patients admitted to the wards during January was 78, and the number treated, 137.

FOREIGN.

Puericulture at a Young Ladies' Seminary.—Professor Pinard is giving a course of lectures on the care of babies before a young ladies' seminary at Paris.

Association of Directors of Sanatoria.—The third annual assembly of the directors of sanatoria in Germany is being held in Berlin this week. One of the principal subjects under discussion is the organization of a training school for attendants which the University Institute of Hydrotherapy has agreed to establish.

Retirement of Hitzig.—Dr. E. Hitzig, director of the clinic for nervous diseases and the polyclinic at Halle, has resigned his professional duties on account of a progressive eye affection. When he organized the clinic for psychiatry and nervous diseases in 1885, it was the first institution of the kind connected with any Prussian university. His name is, perhaps, best known by his studies on cerebral localizations.

Tuberculosis in Germany.—The following facts are gathered by the German department of health:

Out of 1,000 deaths in Germany of persons between the ages of fifteen and sixty, 316 are from tuberculosis. Persons under fifteen and over sixty are seldom affected. The mortality of the whole population has averaged 242 per 100,000 yearly, rising in the Bavarian Palatinate to 329, in Bremen to 337, and in Hesse to 314. The conditions in Germany are shown to be better than in France, Austria, and Russia, but worse than in Switzerland, Belgium, Denmark, Norway, and, especially, England.

Consumption can best be treated in special hospitals, in which Germany now has accommodation for 30,000 patients.

A Spartan School in Switzerland.—The *Journal de Med. de Paris* describes a boys' boarding school in successful operation at Sekingen in Switzerland, near Basle. The boys are brought up in the strictest simplicity and as close to nature as possible. Unusual facilities for bathing are provided, but the water is never warmed. The lads wear sleeveless shirts, sandals instead of shoes, and no caps. The handkerchief is fastened to the belt, as no pockets are allowed. The school has developed many strong boys out of puny ones, and Professor Ringele, the director, is now establishing a school for girls on the same principles.

Charlatans in Berlin and Its Province.—The Berlin Medical Chamber has been collecting information in regard to charlatans, and finds that there are 600 in Berlin alone and 383 in the province. The police have knowledge of 185 cases in which injury has resulted from their practices, proving fatal in 24. Extraordinarily excessive money demands were known in 10. In some of the cases the damage done reacted to the pecuniary disadvantage of sick benefit or life insurance companies. The department of public works has recently ordered the railroad officials to warn the employes explicitly against the dangers of resorting to nature healers.

Silver Jubilee of Prof. F. Bezold of Munich.—A souvenir number of the *Zeitschrift für Ohren-Heilkunde* was presented to Bezold on the twenty-fifth anniversary of his professional career by his pupils and assistants, some of whom had traveled from distant lands to bring their congratulations. The festivities included a speech by six deaf mutes from the Deaf and Dumb Asylum, whose utterance was surprisingly good. They thanked him for his achievements on behalf of the deaf and dumb. The *Muench. Med. Woch.* of February 10 brings an excellent portrait of Bezold, the one hundred and fortieth in its "Gallery of Prominent Medical Men."

Wireless Telegraphy the Invention of a Physician.—The first private wireless message sent across the English channel was from Marconi and was addressed to Dr. E. Branly of Paris. It was a message of congratulation on the success of wireless telegraphy, "due in part," it stated, "to the remarkable labors of Dr. Branly." As long ago as 1890 he reported experiments before the Académie des Sciences which established the practicability of telegraphing without wire communication, and the Comptes Rendus of the Académie and of journals devoted to physics contain many reports by him. He is professor of physics at Paris and the last *Gazette Med. de Paris* contains his portrait and an interview on the subject of his discoveries, which contained the germ of wireless telegraphy and the opening and closing of an electric circuit at a distance.

Struggle to Maintain Ethical Principles.—In Witten, another German city, a conflict between the physicians and the sick benefit society is impending like the one now in progress at Gera. Our readers will remember that the physicians connected with a certain *Krankenkasse* refused to serve longer when a "nature healer" was added to the medical staff on the same terms as the rest. The *Kasse* has been unable, to date, to

find any physicians willing to take their place, although it is advertising for them in the Berlin papers, etc. The Leipsic Verband, or "Union for Protection of the Economic Interests of the Profession," is sustaining the Gera physicians, both morally and materially. They have officially announced that they will aid the *Kassen* members in any emergency, give first aid, etc., but decline further attendance until the "nature healer" is dismissed.

The New Moscow Cancer Hospital.—Professor Lewschin of Moscow has succeeded in organizing a cancer hospital, which is said to be a model in every respect. Contributions of more than $175,000 were collected for the purpose, and the university has taken the new institution under its charge. The word cancer is omitted from its name, and it is known as the "Tumor Clinic and Asylum." Four large laboratories for special research are installed in it, and the operating rooms are lighted by seven large windows and glass roof. All the inner corners and angles are rounded, and the floors slope slightly to the drains. At all the wash rooms there are special cranes and handles, so that the vessels can be washed without touching them with the hands. Lewschin has written a circular of questions concerning cancer patients, which the authorities have sent to 15,000 physicians in Russia, and 5,000 replies have already been received. A recent letter to the *Deutsche Med. Woch.*, in addition to the above items, mentions that the number of deaths from cancer at Moscow has risen from 411 in 1880 to 832 in 1896.

Fourteenth International Medical Congress.—Particulars in regard to the numerous excursions in Spain, open to the members of the congress, have been received at this office. A reduction of 50 to 30 per cent. is allowed on presentation of the coupon membership ticket to be given each member. The transportation is in the hands of the transportation company, the "Voyages pratiques," 9 rue de Rome, Paris, which will furnish further particulars and circulars on demand. Special trains for the members will leave Irun and Port Bou for Madrid on certain dates. The congress will convene April 23 to 30. The committee in charge of lodgings announces that there are a large number of hotels at Madrid whose table and comfort vie with those of the larger European cities, and many of the best private families have volunteered to open their homes to the members, so that thousands of lodgings are provided for, at rates ranging from 13 to 50 pesetas a day, that is, about $2.60 to $10. The committee urges the necessity, however, of early application for lodgings to secure first choice. Mr. Ulrich Frei has charge of the matter, and should be directly addressed. The king and queen regent are to offer the members a garden party and a general reception at the palace. The municipality has organized a special fête with, probably, a gala performance at the Theatre Royal. There will also be a special bull fight for those who wish to visit this national institution. In addition to these general affairs, the sections expect to organize special excursions, etc., for their members. Mail should be addressed to the members, with the name, followed by "Membre du xiv Congrès International de Médicine, Section de ———" (concluding with the name of the country in which the member resides). Membership fees (25 francs, or $5 in a draft on Paris) may be sent directly to the secretary general, Dr. A. F. Caro, Faculté de Médicine, Madrid, or, until March 20, to the national committees. The secretary of the American committee is Dr. Huddlestone, 126 West Eighty-fifth street, New York. Great interest is being manifested in the approaching congress in medical circles in Europe, and it will undoubtedly be a noteworthy gathering of prominent men. It seems probable that the congress will have presented to it the results of much research on serum therapy in various diseases. The complete program may be had of Dr. Huddlestone.

LONDON LETTER.

Lathyrism in Central India.

Lathyrism is prevalent in the central provinces of India. Major Buchanan, of the Indian Medical Service, and Mr. Stockman, professor of pathology in the Edinburgh Veterinary School, have been appointed to inquire into its cause and prevention. It is thought to result from the consumption in large quantities of the food grain known as *Lathyrus sativus*, or teora, when not prepared in such a way as to eliminate a poisonous principle. The clinical features are as follows: For two or three months before the onset the patient has been living almost exclusively on teora, which has been made into cakes and cooked, but not boiled. Then, for a few days, he feels weak and drowsy, with pains in the legs and occasional cramps in the calves. Suddenly, while at work, he falls and finds he is unable to rise. After this he is confined to bed for a month or two, and stops eating teora. The arms are not affected, and there is no loss of sensation, but the lower extremities are paralyzed and, in severe cases, there is loss of control over the sphincters and loss of sexual power. The condition of the leg muscles is one of marked spasticity; the knee jerks are exaggerated, ankle clonus is obtained and, when the patient stands for a few minutes without the aid of sticks, clonic spasms occur in the legs. There is also rigidity of the muscles of the spine, so that when sitting down the patient is unable to turn the upper part of his body around. Improvement is slow, but gradual, whether treatment is adopted or not. There is no fever and little or no muscular atrophy.

Food Poisoning and Epidemic Diarrhea.

At the Epidemiological Society, Prof. Sheridan Delepine read an important paper on the "Bearing of Outbreaks of Food Poisoning on the Etiology of Epidemic Diarrhea." He defined epidemic diarrhea as an infectious disease affecting many persons at the same time, especially during the hot season and in populous districts, where it causes a high infant mortality. Its bacteriology is far from being settled. Most observers believe that the *Bacillus coli communis* is the most important factor, but a spirillum, the *Bacillus enteritidis sporogenes*, various streptococci and *Bacillus lactis ærogenes* have been incriminated by others. Professor Delepine described various outbreaks, which he had examined, especially those of milk diarrhea at Manchester in 1894 and of pork pie and sausage poisoning at Derby in 1902 (recently described in THE JOURNAL). The general conclusions at which he has arrived are that epidemic diarrhea is caused by bacteria of the *Bacillus coli* group, the least virulent being those that most resembled the *Bacillus coli communis* and the most virulent being those that most closely approximate to the *Bacillus enteritidis*, especially the *Bacillus enteritidis* of Gärtner. The most dangerous are, consequently, those that acidify or coagulate milk or impart an offensive odor to it. The obvious precautions to be observed are cleanliness, consumption as early as possible, refrigeration to 4 C., or sterilization by heat.

The Serum Treatment of Poisoning by Snake Venom.

Two very important papers on this subject have been read at the Glasgow Medico-Chirurgical Society. Dr. George Lamb of the Indian Medical Service, who has minutely investigated the subject of snake bites, pointed out that the poisonous snakes of India might be divided into two groups—colubrine and viperine. An example of the former is the cobra, of the latter, the *Daboia russellii*, or chain viper. The poisonous principles of all snakes' venoms are albuminous substances, which vary in different species. Thus cobra venom contains no poisonous principle which is contained in daboia venom and *vice versa*. Hence the symptoms of poisoning by these venoms are very different. When a man is bitten by a cobra severe pain and swelling around the wound occur, after an hour or two nausea and lethargy begin, paralysis soon follows, and death usually takes place about six hours later from failure of respiration. On the other hand, daboia venom causes a large bloody extravasation around the wound, because it has destructive action on the capillaries and red corpuscles, and depresses the action of the heart, sometimes to a fatal extent. Hemorrhage may occur from all the orifices of the body. Paralysis is never produced, and recovery often takes place. Dr. Calmette of Lille, by immunizing horses with a mixture of snake venoms, of which cobra venom is the principal ingredient, has produced an antivenomous serum which is reliable in cases of cobra bite. But Dr. Lamb has found that it is useless in poisoning by daboia venom, and Martin of Melbourne has shown its inability to neutralize the venom of Australian snakes. In the treatment of cobra poisoning the object is to get the serum as quickly as possible into contact with the venom, which is effected by intravenous injection. If this can not be performed the serum may be injected subcutaneously. At least 40 c.c. should be injected. If after injection symptoms occur the dose should be repeated. The only other treatment of any use is tying a ligature about the bite. At present there is no serum for daboia poisoning. Cases can be treated only on general principles; diffusible stimulants help to tide over the stage of cardiac depression.

Dr. Walter K. Hunter then read a paper on the histological appearances of the nervous system in krait and cobra poisoning. His investigations were made on animals killed by Dr. Lamb in the course of his experiments on snake poisoning. In monkeys killed with krait and with cobra venom he found acute degenerative changes in the ganglion cells of the cord, medulla, and

pons, and in the peripheral nerves. In one monkey killed with cobra poison degeneration of nearly every nerve in the central nervous system was produced. In the cervical enlargement of the cord the outlines of the Nissl granules of the antero- and postero-lateral groups were blurred as if they had been acted on by some solvent. The rest of the cells of the anterior were degenerated, and without any granules whatever. In the lumbosacral enlargement these changes were still more marked. In the cerebral cortex there was acute chromatolysis of the majority of the pyramidal cells.

The Professor of Anatomy in the University of Edinburgh.

Sir Wm. Turner having been promoted to the principalship of the University of Edinburgh, the chair of anatomy became vacant. The curators of patronage have appointed Dr. D. J. Cunningham, F.R.S., professor of anatomy in the University of Dublin, to the position. He is pre-eminently qualified, having been eminent in that branch for many years.

PARIS LETTER.

Honors Paid to Professor Brouardel.

Professor Brouardel, who was replaced last year by Professor Debove as dean of the faculty, was recently made a grand officer of the Legion of Honor, and on this occasion a fitting tribute was paid to Brouardel's work as professor of legal medicine. The ceremony took place in the large amphitheater of the Faculty of Medicine, and the minister of public instruction, Chaumié, was present, as well as Liard, the vice-rector of the academy, and other high dignitaries of the university. Professor Gilbert, a pupil of Brouardel, made a speech, in which he showed how Professor Brouardel had always sacrificed his private interests for the general welfare, giving up his laboratory work, his practice and his hours of rest or recreation when his professional duties required his doing so. Dr. Marey, a member of the institute, who is so well known for his work on physiology, had written a speech which was read by Chauveau, as he was ill at the time. Dr. Debove also made a speech in which he made the remark that he trusted his successors would leave the deanship with as much affection and sympathy shown by their pupils and colleagues, which reminds one that Dr. Debove has not been in great favor with the students of the Paris Faculty. The minister, Chaumié, spoke of Brouardel's recent efforts in the campaign against tuberculosis.

Terrier's Statistics in Appendicitis.

Almost all the important surgeons in Paris are publishing their statistics on appendicitis at the weekly meetings of the Society of Surgery. Professor Terrier has been one of the last to do this. His statistics include three years' work at La Pitié, 1900-1901-1902. He divides operations into three categories: urgency operations, operations "*à chaud*," operations "*à froid*." Thirty-nine urgency operations furnished four deaths, or 10.25 per cent. mortality. The second type of operation was performed 17 times with one death, or 5.88 per cent. mortality. Of the last variety there were 61, with one death, or 1.80 per cent. The grand total is 117 operations with 6 deaths, or 5.12 per cent. mortality.

Cure of Gin Liver by the Internal Use of a Hog's Liver.

At a recent meeting of the Medical Society of the Hospitals, Dr. Galliard reported the case of a woman, 54 years old, who was suffering from cirrhosis of the liver. Various drugs were tried without effect, and, at last, she was given daily 150 grams of the liver of a pig. The urine soon became clearer and more abundant, the symptoms improved, and now she seems to be quite cured.

Faure's Second Operation for Cancer of the Esophagus.

Dr. Faure, surgeon at the Hotel Dieu, had already operated last December, on a case of cancer of the thoracic portion of the esophagus, and the patient died the next day. In a second case, which was operated on recently, Dr. Faure did not excise the first rib as before, but was able to remove a part of the esophagus eight centimeters long. The operation was done in both cases on the right side, though Drs. Quenu and Hartmann consider it best to operate from the left side on account of the pleural sinus. The latter was not, however, in the way, whereas on the left side the aorta might render the operation more difficult.

Hydrocele Containing Tuberculous Bacilli.

At a recent meeting of the Society of Surgery, Dr. Tuffier presented two patients who had been treated for simple hydrocele and who showed no trace of genital tuberculosis. The effusion had been treated by Jousset's method of centrifuging and had been found to contain tuberculous bacilli, which would tend to show that in a certain number of cases hydrocele was of tuberculous origin.

Infantile Scurvy.

At a recent meeting of the Obstetrical Society, Dr. de Rothschild reported the recent statistics of infantile scurvy, which show that this affection is exceedingly rare in France, there being only 23 cases reported. It is, however, frequently seen in Germany, Baginski coming across 8 or 10 cases yearly. The latter author has ever cited instances where the child was fed from the breast. Professor Budin, the great advocate of feeding with sterilized milk, said he had never seen a single case of the disease and, as he uses sterilized milk, he feels that it must have some other etiology. In connection with this it may be stated that at a recent meeting of one of the medical societies of Paris a certain variety of sterilized milk was spoken of as having been given to a child suffering from scurvy. It is a noteworthy fact that in the reports that appeared in the medical papers no mention was made of the name, the milk being spoken of as sterilized milk.

Correspondence.

The Diploma vs. Examination.

PEORIA, ILL., Feb. 23, 1903.

To the Editor:—Your remarks in your issue of February 21 under the caption "The Diploma vs. Examination" lead me to a desire to know your reasons for the position therein taken. The question involved is a particularly vital one at the present stage of legislative effort on the part of the profession of the state of Illinois, and a goodly number, including myself, entertain views diametrically opposed to those you have expressed. If the judgment of such is erroneous, I for one should like to have it corrected by efficient arguments. The action of a majority of our state or territorial legislatures is not alone conclusive, in that a particularly active coterie of medical men may, as we have had reason to know, secure legislation not representative of the sentiments of the profession as a whole.

I can not conceive of the likelihood of procuring, under existing political conditions in and out of the profession, a central examining board so constituted as to secure, in the time and with the opportunities ever at its disposal, a superiorly adequate knowledge of any individual's fitness for the practice of medicine. If the possession of a diploma is to be considered a prerequisite to examination, either as an excuse for laxity or a safeguard against omissions, it seems to me a confession of weakness of the whole cumbersome scheme of a central examining board and its associate committees. In my judgment it were far easier and more practicable, and more in harmony with the economic and centralizing spirit of the time, for a small number to authoritatively investigate and pass on the educational merits of fifty or one hundred institutions of learning, occasionally, than to adopt the task of perpetually investigating the qualifications of thousands of individuals. Instructors, or even some special individual appointed for the purpose, must, it seems to me, be acknowledged to be in a better position, through constant association with students and their course of work, to judge of their all-around fitness than can be any company of individuals armed with a mere series of stock questions entirely unassociated with any opportunity for their practical application. O. B. WILL.

Ἀχιλλέυς ἀνέστη Χωόμενος.

Achilles Rose in His Wrath.

BROOKLYN, Feb. 25, 1903.

To the Editor:—In THE JOURNAL of February 14 there appeared a letter from one, Achilles Rose, M.D., who seems to have a grievance of some kind. Our attention has just been called to his amusing invective. The editors of the *Medical Library and Historical Journal* doubtless would have qualified as "men of learning" if only the journal had been published in modern Greek. This "monstrosity" might then have seemed

as sweet as "A Rose of Yesterday." Alas! we are not "men of learning," and we do not claim to be—we are only men who are learning. There is only one man of learning, only one—and he will not quote titles of books "because many of these titles are misspelled." We are desolate. We once knew of a woman who never married because some men are bad. All mankind grieved.

The writer acknowledges the justness of the criticism of Achilles Rose, M.D., as to there being some misspelled titles in the 17-page list of "New Medical Publications" published in the initial number of the *Journal*. Typographical errors will creep in, and in this instance circumstances, unfortunately, prevented this list from receiving the careful revision the editors will be able to give it in the future. Then, if the eyes of "The Great Corrector" perchance ever again should see this "monstrosity" perhaps his grief will be somewhat assuaged.

We like just criticism and take it kindly. We solicit it. Criticism is the index finger pointing to progress. Thank God, we have not the slightest idea that we have reached a state of perfection.

The Medical Library and Historical Journal,
ALBERT T. HUNTINGTON, Editor.

Registrations at the Madrid Congress.

The following circular letter is self-explanatory:

CINCINNATI, Feb. 24, 1903.

Dear Doctor:—Some time last year I received a lot of application blanks from the secretary of the International Medical Congress of Madrid, and, in turn, forwarded them to the members of the A. A. O. G., requesting such as desired to fill out the same and return them, with the admission fee of $6. I received in return a number of applications, with checks, etc., and forwarded them to Madrid, with the request that the registration tickets be forwarded direct to the subscribers. I heard nothing more of the matter, and entirely overlooked the fact that I failed to receive my own admission ticket, until I received, to-day, advice as follows:

> Your very gracious letter, enclosing 126 pesetas, was duly received. I am, however, full of humiliation to advise you that the accompanying applications were mislaid. We have tried to find them, but, at the last moment, forced to abandon the effort. If you will be so kind as to again forward the names, the certificates will be made out at once.

I have no memorandum of those who subscribed, and write to ask whether or not you sent your subscription to me. If so, kindly advise me, and I will at once forward the information to Madrid.

Please let me hear from you by return mail.

Very sincerely yours,
CHAS. A. L. REED.

Anti-Infectious Action of Crede's Collargol.

To the Editor:—In your issue of December 20 I notice with much surprise and regret an editorial, "Anti-Infectious Action of Credé's Collargol," in which the statement is made that, because the bacteriologic investigations of Cohn in Pfeiffer's laboratory (Königsberg) have given negative results, and because 45 minutes after introduction into the circulation colloid silver is no longer demonstrable in the blood, its fate as a specific against sepsis is settled.

It seems that you expect from collargolum a powerful bactericide effect, as from sublimate or nitrate of silver; if it possessed an action of this character, it could never be introduced so freely into the system. As, however, Professor Wenckebach (director of the Groningen University Medical Clinic) states, collargolum is a powerful catalysator in the body, and hence can only enhance the normal bactericide properties of the blood.

Bacteriologic experiments are incompetent to determine the efficacy or inefficacy of collargolum, since its action is only developed in the body, and in the presence of pathogenic bacteria or their toxins, with which it forms combinations, while in sterile blood or lymph it remains metallic silver.

I am sorry that in this editorial you have brushed aside the clinical testimony of such men as Professors Roswell Park, A. Jacoby, S. Marx, Chas. G. Cumston, H. J. Boldt, Dieckerhoff, Tillmanns, Walter B. Dorsett, George M. Coon, Forchheimer, Drs. Gustav Schirmer, Oscar Werler, and many others, whose reports you will find in our pamphlets of March, 1899; March, 1900; October, 1900; March, 1901; October, 1901; March, 1902, and October, 1902, which we send you by this mail, separately. I do not remember having ever seen a single clinical report "denying all claims of efficacy" for collargolum; if such have been published their number is utterly insignificant to that of the favorable ones. Your very truly, C. F. STEIFEL.

A Sample Health Board Propaganda.

DETROIT, MICH., Feb. 28, 1903.

To the Editor:—I accepted the appointment as a member of the Detroit Board of Health from Governor Pingree, Feb. 21, 1899, for the term ending Feb. 28, 1903.

On March 15, 1899, certain thoughts of mine appeared in the *Detroit Evening News* concerning the workings of the Detroit Health Department, and the kind of man needed as health officer. These thoughts later became my convictions, and were contained in my fixed policy, and were, viz.:

(*a*) Health officer to be a clinical physician with executive ability, and to have had personal experience diagnosing contagious diseases, including smallpox, scarlet fever and diphtheria.

(*b*) Health officer to examine *personally* suspicious or doubtful cases reported to the department, and meet *personally* private physicians asking consultation thereon.

(*c*) Health office to be operated on practical business principles, and without political coloring.

(*d*) Methods of health office to be up-to-date, but for every dollar of cost of maintenance the department to obtain full value in practical results—all unnecessary expense to be eliminated.

(*e*) All health department work of a medical nature to be performed by the salaried physician employes of the city.

(*f*) Health officer and all employes to give their entire time to the department. Under no circumstances should persons on regular salary be paid extra compensation.

Spencer says: "Political life is healthy only in proportion as it is conscientious." I have endeavored faithfully to enforce the above policy, as well as all health laws and ordinances applicable to Detroit, with what success the official records of the Detroit Board of Health will show.

JOHN L. IRWIN, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

MEDICAL PRACTICE QUERIES.

GRAND RAPIDS, MICH., Feb. 27, 1903.

To the Editor:—I am a graduate of a recognized medical college and am registered in Michigan. I wish to move to California. I understand that there is reciprocity between Illinois and California and between Michigan and Illinois. Is this true? Now, would it be allowable for me to register in Illinois and from there register in California? If not, what will I have to do to practice in California? Kindly answer in your "Queries." J. S. RANDALL.

ANS.—Illinois reciprocates on certain conditions with Michigan, but not with California yet. An examination will probably be required in California.

JOHNSON CREEK, WIS., March 2, 1903.

To the Editor:—Kindly let me know through the Queries and Minor Notes department of THE JOURNAL which state boards of medical examiners reciprocate and on what basis? MICH.

ANS.—Delaware reciprocates with New Jersey and Maryland; Illinois with Indiana, Maine, Michigan, New Jersey and Wisconsin; Indiana with Michigan, Wisconsin and Illinois; New Jersey with Delaware, Maine and Illinois; Maine with Illinois and New Jersey.

Some states accept certificates of certain others—thus Pennsylvania accepts those of New York, and Texas those of some twenty other states—Delaware, District of Columbia, Georgia, Iowa, Louisiana, Maryland, Mississippi, Missouri (if issued after July, 1901), Montana, Nevada, New Hampshire, New Jersey, New York, North Carolina, Oregon, Pennsylvania, South Carolina, Utah, Virginia, **Washington.**

Marriages.

JOHN J. ZAUM, M.D., to Miss Gertrude Anderton, both of Milwaukee, Wis., February 24.

ISAAC A. THOMPSON, M.D., to Miss Alma M. Despres, both of Traverse City, Mich., February 25.

JOSEPH A. GUERTIN, M.D., St. Mary, Ill., to Miss Amy Grossaint of L'Erable, Ill., February 18.

JOHN G. MCKINNEY, M.D., Barry, Ill., to Mrs. Electa Henry of El Dara, Pike County, February 18.

JAMES W. BLAN, M.D., La Fayette, Ill., to Miss M. Mollie Gochring of Warsaw, Ill., February 18.

ROBERT STANLEY GOODMAN, M.D., Oakhill, Fluvanna County, Va., to Miss Mary Dixon Boggs, of Baltimore, February 17.

RICHARD M. FLETCHER, JR., M.D., acting assistant surgeon, U. S. A., to Miss Anna Ford Ludlow of Chicago, February 12.

Deaths.

T. Gaillard Thomas, M.D.

Theodore Gaillard Thomas, M.D., of New York City, died in Thomasville, Ga., February 28, aged 71. Dr. Thomas was one of the pioneers in American gynecology; as a teacher and

T. GAILLARD THOMAS, M.D.

clinician he was unsurpassed in his day; his courtesy and kindness of heart endeared him to the thousands of students whom he instructed, and to his brothers in the profession, and his sympathy and chivalrous tenderness endeared him to his patients.

Theodore Gaillard Thomas was born at Edisto Island, S. C., November 21, 1831. His early education was received in Charleston (S. C.) College, which he left in his senior year to enter the Medical College of the State of South Carolina, Charleston, from which he was graduated in 1852. He settled in New York City immediately after graduation and was resident physician at Bellevue Hospital, and New York City Hospital, Blackwell's Island. He soon devoted his attention especially to obstetrics and diseases of women. He was for many years professor of obstetrics and diseases of women and children in the College of Physicians and Surgeons, New York; physician to Bellevue Hospital; surgeon to the Woman's Hospital in the State of New York; consulting surgeon to Nursery and Child's, French Lying-In, Skin and Cancer, Presbyterian, and St. Mary's hospitals. He was also at one time physician to Bellevue, St. Luke's, Roosevelt and the Strangers' hospitals.

He was a member of the American Medical Association; a founder, and in 1891, honorary fellow of the American Gynecological Society; a member and once president of the New York Obstetrical Society; a member of the New York State Medical Association, New York Academy of Medicine, New York County Medical Society, and New York Pathological Society; honorary fellow of the Obstetrical Society of London; corresponding fellow of the obstetrical societies of Berlin, Philadelphia and Louisville.

His work entitled "Diseases of Women" has been for many years a standard text-book.

His funeral was held in New York City, March 3, and was largely attended. Members of medical societies of which he was a member, hospital staffs on which he had served and the faculty of the College of Physicians and Surgeons were present in great numbers to pay the last honors to their deceased colleague.

W. E. B. Davis, M.D.—The later reports are still indefinite as to the manner in which Dr. Davis met his death. One account says that he got out of his buggy to go to his horse's head, when the animal reared, throwing him under the wheels of the train; another, that he lost his footing and fell under the train; another, that he did not take hold of the horse's bridle, but threw himself under the train; a fourth, that he was drawn under the moving train by the suction, and a fifth, that as he was about to sieze his horse's bridle he was struck by the step of the coach and thrown under the train. The wheels of the rear truck passed over his body just above the hips, not breaking the skin. His right leg was broken and his face showed abrasions.

The body lay in state at his late residence for six hours on February 26, and hundreds took advantage of the opportunity to look on his face for the last time. The funeral ceremonies were marked by the simplicity which was characteristic of the deceased.

The *Age-Herald*, in an editorial mention of Dr. Davis' death, says: "He held not only a high place among the surgeons of this state, but he was widely known in other states. It may be said that he was esteemed by eminent surgeons throughout this country, and even in other countries. Here at home those to whom his skill and deep knowledge of the human frame had come are inconsolable, and in their homes the loss will be grievously felt. He was as tender-hearted as he was skilful, as genial and lovable as he was helpful and scientific. He was loved as a man and respected as a great surgeon. The loss of this people is heavy, and the grief of those to whom he was a companion and friend is beyond the power of words to express."

The newspaper also states: "The scenes at the infirmary were deeply pathetic. The white-capped nurses went quietly about their hospital duties, but in the atmosphere was the appalling hush of death. These good women would pass each other in the long, silent corridors, but their lips were mute. They passed in and out of the sick chambers and carried out to the minutest detail the instructions left by the physician whose end came so suddenly. Every white bed had its sufferer looking for relief to a life that had just gone out. They watched and waited the long afternoon and grew restless at the delay. And yet never a word of the tragedy came from the lips of the white-capped nurses, never a hint of the accident that was being discussed in the streets, at the clubs, in thousands of homes, in the most fashionable avenues and in the poorest districts of the city."

Franklin M. Kemp, M.D. Long Island College Hospital, Brooklyn, 1893, died from heart disease at Nueva Caceres, Philippine Islands, February 23. After his graduation Dr. Kemp served as assistant surgeon in the Soldiers' Home, Dayton, Ohio, and in 1896 was appointed first lieutenant and assistant surgeon in the Army. He served in Vancouver Barracks and Alaska, and in 1898 went to Manila, where he served under General Lawton, and twice was mentioned in despatches for bravery. He was invalided home in 1899, and was on duty at the United States Military Academy, West Point. He was made captain and assistant surgeon in 1901, and ordered back to the Philippines. He was a member of the Association of Military Surgeons of the United States.

Cochran McClelland, M.D. Jefferson Medical College, Philadelphia, 1873, formerly assistant to Prof. Ellerslie Wallace, a well-known gynecologist and obstetrician of Philadelphia, and a member of the American Medical Association, and the Philadelphia County Medical Society, died at his home in Philadelphia, February 16, from pneumonia, after an illness of two weeks, aged 53.

Caird Ryerson Maclean, M.D. Faculty of Medicine of Queen's University and Royal College of Physicians and Surgeons, Kingston, Ont., 1859; M.R.C.S. Eng., 1879, surgeon-lieutenant-colonel, a veteran of the Civil War, through which he served as surgeon, died at his home in Meaford, Ont., February 17, from paralysis, after a long illness, aged 65.

David Miller Anderson, M.D. Bellevue Hospital Medical College, New York, 1866, assistant surgeon in the Civil War, and three times a member of the Pennsylvania legislature, died at his home in Venetia, February 16, from pleuro-pneumonia, after an illness of two weeks, aged 65.

Robert Rose Dorsey, M.D. University of Pennsylvania, Philadelphia, 1882, fourth of his family in linear descent to practice medicine, died from consumption at his home in Los Angeles, Cal., February 18, from consumption, aged 43.

A. L. Cressler, M.D. Jefferson Medical College, Philadelphia, a member of the legislature in 1874, and a charter member of the Luzerne County Medical Society, died at his home in Wilkesbarre, Pa., February 23, aged 75.

Thomas Atkinson Councell, M.D. College of Physicians and Surgeons, Baltimore, 1894, of Easton, Md., health officer of Talbot County, died at the City Hospital, Baltimore, from Bright's disease, February 18, aged 30.

James E. Ferguson, M.D. Philadelphia Medical College, 1852; Jefferson Medical College, Philadelphia, 1870, twice a member of the state legislature, died February 16, at his home in Bangor, Mich., aged 78.

Ingham Wood Donnan, M.D. Bellevue Hospital Medical College, New York, 1871, of South Side, Pittsburg, Pa., died from consumption at Aiken, S. C., February 13, after a long illness, aged 58.

Peter V. R. Dafoe, M.D. University of the Victoria College, Cobourg, Ont., 1864, of Tecumseh, Neb., died from consumption, February 17, near Macon, Mo., while returning home from Florida, aged 64.

Edward E. Baker, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1887, of Friendship, Maine, died recently from consumption at Jefferson, Maine, after an illness of three years.

David A. Kappes, M.D. Jefferson Medical College, Philadelphia, 1884, a specialist on diseases of the eye, died from pneumonia at his home in Philadelphia, February 14.

John J. Conway, M.D. Long Island College Hospital, Brooklyn, 1880, died from pneumonia at his home in Brooklyn, after an illness of one week, February 13, aged 44.

Benjamin Bevan, M.D. New York University, 1890, died at his home in West Pittston, Pa., February 20, from myelitis, resulting from a fall, after a long illness, aged 41.

Martin B. Cherrie, M.D. Rush Medical College, Chicago, 1888, died at his home in Ankeny, Iowa, February 20, from consumption, after an illness of nearly four years.

Charles C. Conway, M.D. Washington University School of Medicine, Baltimore, 1869, died at his home in Orange County, Va., February 17, after a long illness, aged 70.

Alice H. Burdick, M.D. Eclectic Medical College of the City of New York, 1872, was struck by a train and instantly killed at Passaic, N. J., February 19, aged 60.

Carlos R. Allen, M.D. Dartmouth Medical College, Hanover, N. H., 1838, the oldest practitioner in Sussex County, Va., died at his home in Vernon, February 19, aged 88.

William J. Springfield, M.D. Cleveland College of Physicians and Surgeons, 1874, died recently from pneumonia at his home in Jolly, Daviess County, Ky.

Henry Addison Mandeville, M.D. College of Physicians and Surgeons, New York, 1891, died at his home in South Orange, N. J., January 31, aged 45.

D. Erastus Thomas, M.D. Medical College of Evansville, Ind., 1851, of Lacon, Ill., died at St. Petersburg, Fla., from heart disease, February 5, aged 78.

Pacificus B. Porter, M.D. Chicago Medical College, 1869, of Chicago, died suddenly in a drug store in Ravenswood, February 9, from heart disease, aged 57.

Elizabeth McFarland, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1901, died at Sharon, Pa., from broncho-pneumonia, February 7.

Henry Helfrich, M.D., a retired homeopathic physician of Allentown, Pa., died at his home in that city, February 1, from pneumonia, aged 99.

Benjamin R. Dostor, M.D. Jefferson Medical College, Philadelphia, 1858, died at his residence in Blakely, Ga., February 15, from Bright's disease.

William W. Wilkes, M.D. Louisville Medical College, 1871, died at his home in Waco, Texas, January 29, after an illness of several weeks, aged 56.

William Y. Howard, M.D. University of Louisville, Ky., 1888, died from hemorrhage of the stomach at his home in Louisville, February 2.

Hiram W. Alexander, M.D. University of Nashville (Tenn.), 1857, died at his home in Muir, Fayette County, Ky., February 24, aged 73.

Robert W. Norwood, M.D. University of Tennessee, Nashville, 1894, died at his home in West Nashville, Tenn., January 26, aged 43.

Jonas Watkins, M.D., an eclectic physician of Blanchester, Ohio, died at his home in that city, February 3, from apoplexy, aged 74.

John Tatman, M.D. Indiana Medical College, La Porte, Ind., 1840, died at his home in Mitchell, S.D., February 2, aged 85.

Bishop B. Sudworth, M.D. University of Michigan, Ann Arbor, 1883, died at his home in Ann Arbor, February 15, aged 73.

Herman S. Bissey, M.D. University of Pennsylvania, Philadelphia, 1880, died at his residence in Philadelphia, February 22.

Tousley B. Lewis, M.D. University of Buffalo, 1879, died at his residence in New York City, February 8.

Isaac Sanders, M.D., died at his home in Fordsville, Ky., January 29.

Book Notices.

THE WORK OF THE DIGESTIVE GLANDS. Lectures by Professor J. P. Pawlow, Director of the Physiological Department of the Institute for Experimental Medicine. Translated into English by W. H. Thompson, M.D., M.Ch., F.R.C.S. (Eng.). King's Professor of the Institute of Medicine, Trinity College, Dublin. Illustrated. Cloth. Pp. 196. Price, $2.00. London: Charles Griffin & Co., Ltd. Philadelphia: J. B. Lippincott Co. 1902.

This is a translation of the lectures delivered by Professor Pawlow before a gathering of medical men in the St. Petersburg Institute for Experimental Medicine, before the Russian Medical Academy, etc. Since his audience was made up of men who were not supposed to know of the methods or results of his experimental work, he presented his facts in the simplest language, so that the least learned could understand; at least this is the opinion one would get from reading the English translation. It is barely possible that the translator should have credit for a part of this. In any event, even the ordinary intelligent layman will find the book intelligible, but, above all, easily readable and almost fascinating. The lectures give an account of Pawlow's great work in his physiologic laboratory connected with the St. Petersburg Institute for Experimental Medicine and of the splendid results achieved. We commend these lectures to every physician, whether he is interested in experimental medicine or not. It can not but stimulate every one who reads the book. The general reader will find in it food for thought and, at the same time, relaxation. It is a pity that the American publishers have given us a reprint of the English edition, which is in small type. The matter is deserving of, and the reader is entitled to, a larger type, especially at the price charged.

THE PRACTICAL MEDICINE SERIES OF YEAR-BOOKS. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume III. The Eye, Ear, Nose and Throat. Edited by Casey A. Wood, C.M., M.D., Albert H. Andrews, M.D., and T. Melville Hardie, A.M., M.D. December, 1902. Cloth. Price, $1.50. Chicago: The Year-Book Publishers.

This small book contains a good collection of articles, mostly abstracts, which are very interesting and instructive reading.

One of the subjects in the chapter on nose and throat of special interest to a considerable number of physicians, is the effect of the suprarenal solution on the mucous membranes. Some writers claim it is of value as an anesthetic and of little value as a hemostatic, while others claim the opposite effect. One case is reported of a severe hemorrhage in a case of hemophilia which was controlled in thirty-six hours. Vansant claims that if the solution is applied by means of cotton wool, the usual anesthetic effect of cocain is increased and prolonged and is equivalent to that produced by a strong solution of cocain. This is due, Oppenheimer says, to the prevention of hemorrhage and the consequent loss of cocain from the tissues. It is also claimed that this temporary anemia retards healing and causes excessive sloughing of tissue following operation. We have noticed that the adrenalin apparently prolonged the anesthetic effects of cocain, but we doubt the correctness of the observation about sloughing.

HUMAN ANATOMY. A Complete Systematic Treatise by Various Authors, Including a Special Section on Surgical and Topographical Anatomy. Edited by Henry Morris, M.A., and M.B. Lond., F.R.C.S. Eng., Member of the Council (Lately Vice-President) of the Royal College of Surgeons of England. Illustrated by 846 Wood Cuts, the Greater Part of Which Are Original and Made Expressly for This Work by Special Artists, 266 Printed in Colors. Third Edition, Revised and Enlarged. Cloth. Pp. 1328. Price, $6.00. Philadelphia: P. Blakiston's Son & Co. 1902.

It might seem on first thought that the frequent revision of a work on such an apparently fixed subject as anatomy would not be required, but such is not the case. Not only are many new points in the finer anatomy constantly coming out, but our comprehension of the meaning of many anatomic facts change with increasing knowledge of embryology, comparative anatomy, etc. Methods of teaching also undergo changes, so that it is as essential that a work on anatomy, in order to be modern, should be subjected to revision almost as frequently as text-books on other subjects. In this, the third edition, we notice many changes, noticeably the addition of a number of new illustrations, both colored and diagrammatic, which facilitate materially the study of this, to students, usually dry subject. The sections on surgical and topographic anatomy and on vestigial and abnormal structures are particularly interesting and instructive to the practitioner as well as the student. The matter is well arranged, and the whole work one of the best on the subject.

PROGRESSIVE MEDICINE. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Assisted by H. R. M. Landis, M.D., Assistant Physician to the Out-Patient Medical Department of the Jefferson Medical College Hospital. Volume IV. December, 1902. Diseases of Digestive Tract and Allied Organs; Liver, Pancreas and Peritoneum—Anesthetics, Fractures, Dislocations, Amputations, Surgery of the Extremities, and Orthopedics—Genito-urinary Diseases—Diseases of the Kidneys—Physiology—Hygiene—Practical Therapeutic Referendum. Cloth. Pp. 422. Price, $1.50. Philadelphia and New York: Lea Brothers & Co. 1902.

This work, which is really a serial in book form, contains in the present issue a digest of medical science under the heads given above. Each of these chapters is written by a known expert. The first is by Dr. Max Einhorn, whose authority no one will question; the second, on anesthetics and operative surgery, is by Dr. J. C. Bloodgood; that on genito-urinary diseases by Dr. William T. Belfield; the chapter on diseases of the kidneys is by Dr. John Rose Bradford, F.R.C.P.; a summary of the physiology is made by Dr. Albert P. Brubaker; hygiene is treated by Dr. Charles Harrington; the therapeutics section by Dr. E. Q. Thornton. The book, with its other quarterly issued volumes, is an epitome of medical progress which, we think, few physicians can afford to be without.

APPLIED SURGICAL ANATOMY Regionally Presented for the Use of Students and Practitioners of Medicine. By George Woolsey, A.B., M.D., Professor of Anatomy and Clinical Surgery in the Cornell University Medical College. With 125 Illustrations, Mostly Colored. Cloth. Pp. 521. Price, $5.00. New York and Philadelphia: Lea Brothers & Co. 1902.

The practitioner soon learns to distinguish between the descriptive anatomy of the text-book and the practical or applied anatomy of the operating room and the bedside. Not that there is any difference in the anatomy, but the practical application of anatomic points in medical and surgical cases is a study in itself. The author appreciates thoroughly this fact, and it has been his aim to bring before the practitioner applied anatomy in a practical, interesting and instructive manner. We may add, too, that he has succeeded exceedingly well, for the work is replete with useful and valuable facts and suggestions. There are a number of minor defects and errors, such, for instance, as the promiscuous use of inches and centimeters in measurements; the statement that the cranial bones never reproduce lost portions; that the speech center in right-handed persons is on the right side, etc., but these can easily be corrected in future editions, and should not be allowed to detract from the worth of the book. It is well worth careful study, and can be recommended.

ATLAS AND EPITOME OF DISEASES OF THE MOUTH, PHARYNX, AND NOSE. By Dr. L. Grunwald, of Munich. From the Second Revised and Enlarged German Edition. Edited, with Additions, by James E. Newcomb, M.D., Instructor in Laryngology, Cornell University Medical School. With 102 Illustrations on 42 Colored Lithographic Plates and 41 Text-cuts. Cloth. Pp. 219. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1903.

This is a small octavo volume, one-half of which is devoted to colored plates of the various lesions of the mouth, pharynx, nasopharynx and nose, with descriptive text, and 212 pages which also contain numerous illustrations. It is devoted largely to the special pathology and treatment of the more important classes of diseases involving these organs. The book is concise and well written, and will be a boon to many of the younger specialists and to physicians who are not thoroughly familiar with the diseases of these organs. The author may be heartily congratulated on the excellence of his work and the translator on having furnished a valuable addition for the libraries of Americans who are not thoroughly familiar with German.

TASCHENBUCH DER MASSAGE. Für Studirende und Aerzte. Von Dr. Erich Ekgren an der III medicinischen Universitätsklinik zu Berlin. Mit einem Vorwort von Geh. Med.-Rath Prof. Dr. H. Senator. Mit 11 Abbildungen. Cloth. Pp. 90. Berlin: S. Karger. 1903.

This is perhaps the most concise little manual for the physician that we have seen. Of course, to those who do not understand German its usefulness would be very limited, though the illustrations are numerous and helpful. The author has condensed in less than 100 pages a large amount of instruction, and it seems to us there ought to be many physicians who can make use of the book. It has an advantage, not so common in many works of its size, of a convenient little index, and contains a list of the latest literature, which is, of course, as given in a German work, almost exclusively German.

BACTERIOLOGICAL TECHNIQUE. A Laboratory Guide for the Medical, Dental, and Technical Student. By J. W. H. Eyre, M.D., F.R.S. Edin., Bacteriologist to Guy's Hospital. With 170 Illustrations. Cloth. Pp. 375. Price, $2.50 net. Philadelphia and London: W. B. Saunders & Co. 1902.

This work is intended as a guide to the medical student in bacteriology and is fairly well suited for its purpose. There is hardly any book that we can well compare to it, except perhaps that of Novy, which is one or two years behind it in point of publication.

Miscellany.

THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH.

A Statement of Work and Plans.

The Rockefeller Institute for Medical Research was founded in 1901 by Mr. John D. Rockefeller, who gave for this purpose the sum of $200,000. The aims of the institute are the promotion of medical research, with special reference to the prevention and treatment of disease.

It was thought wise by the directors of the institute not, at first, to concentrate the work in any one locality, but to enlist the interest and co-operation of such investigators throughout the country as might be engaged in promising researches or who might enter on new fields if suitable pecuniary assistance could be afforded them. It was the conviction of the directors that in this way it would be possible not only to stimulate and foster valuable contributions to science, but also to secure important practical suggestions as

to the lines along which the institute might most wisely develop.

Among the large number of applications for assistance in carrying on original studies which relate to the cause, prevention and cure of disease and to the problems on which new knowledge on these subjects must be based, over twenty have been selected. The directors have secured counsel in these selections from the heads of departments or others in the universities of Harvard, Yale, Johns Hopkins, Pennsylvania, Columbia, New York, Chicago, Michigan, McGill, Wesleyan, California and Western Reserve, and in many of these institutions work has been prosecuted. Two of the Rockefeller fellows have been working in Europe. Some of the workers under these Rockefeller Institute grants, which vary in amount from $200 to $1,500, have completed and published their investigations; some are still engaged on them.

It is the purpose of the directors from time to time to bring together, in the form of volumes of collected reprints, the results of these researches, which may be published in various technical journals. An arrangement has been effected by which the institute will assume the publication of the *Journal of Experimental Medicine*, which will remain under the editorial supervision of Dr. William H. Welch, professor of pathology in the Johns Hopkins University, and president of the board of directors of the institute.

At the end of the first year of practical work of careful study of the situation, it became clear to the directors that existing institutions in this country, while in many instances carrying on most valuable researches in medicine, do not afford adequate facilities for many phases of investigation which are of the utmost importance and urgency. This is, in part, due to the lack of sufficient endowment, in part to the large demands made on the time and energy of the workers by their duties as teachers. It was further evident that such assistance as the institute had thus far been enabled to extend to selected investigators in various parts of the country had fostered work of great actual value as well as of high promise and should be perpetuated along similar lines.

The directors, however, were united in the conviction that the highest aims of the institute could not be secured in this way alone. Useful as such individual studies are, and important as it is to enlist and to maintain the interest of research workers in established institutions of learning, it is not possible in this way to secure the unity of aim and the co-ordination and mutual stimulus and support which are essential to the highest achievements in research. These are to be secured, it was believed, only by the centralization of certain lines at least of the work of the institute under a competent head or series of heads of departments, in a fixed place, with adequate equipment and permanent endowment.

There is no lack of men of sufficient training and experience ready to devote their lives to the solution of medical problems which bear directly or indirectly on the welfare of mankind. The widely open fields of research are many. Some of these relate to the application of existing knowledge to the prevention and cure of disease; others to the development of new knowledge along various lines of science, which, more than ever before, give promise of great significance in the problems of physical life.

In a broad sense, the directions and methods for the study of disease may be classified as morphologic, physiologic and chemical, and the institute, it was thought, should include departments providing for these divisions of the subject. For the morphologic study of disease there should be a complete equipment for pathologic-anatomic research. For the physiologic study of disease provision should be made for experimental pathology, for pharmacology and therapeutics, for the study of bacteria and other micro-organisms, with special reference to their relation to the infectious diseases, and for other investigations in personal and public hygiene, including preventive medicine. Here belong, especially, the problems of infection and immunity, and here also, in large part, such studies as require access to patients in hospitals. There should be a laboratory, well-equipped for investigations in physiologic and pathologic chemistry.

It was the conviction of the directors that such an institute might wisely add to its aims in the direct increase of the knowledge of disease and its prevention and cure, a phase of activity which should look toward the education of the people in the ways of healthful living, by popular lectures, by hygienic museums, by the diffusion of suitable literature, etc. For, in fact, the existing agencies for medical research for the most part stop short of those direct and widely diffused applications of newly won knowledge, on which the immediate practical fruitage of their work so largely depends.

In order that the causes and treatment of human disease may be studied to the best advantage, it was the opinion of the directors that there should be attached to the institute a hospital for the investigation of special groups of cases of disease. This hospital should be modern and fully equipped, but it need not be large. It should attempt to provide only for selected cases of disease, and the patients would thus secure the advantages of special and skilled attendance and such curative agencies as the institute might develop or foster.

It was thought that an institute for medical research of the largest promise would require a central institution, fully equipped and endowed, and with capacity for growth, in which the more comprehensive studies demanding the co-ordinated forces of various phases of science could be carried on from year to year; while, at the same time, by means of such grants of assistance as had been offered during the initial year, it should continue to make available the resources of special workers all over the country, as well as in Europe.

In view of the above considerations relating to its future, in June, 1902, Mr. Rockefeller gave to the institute the sum of $1,000,000 for the purchase of suitable land, the erection of buildings, and the organization of a working force along the broader lines which had been projected. It is the purpose of the directors to proceed at once to the erection of a laboratory building which will provide for the present requirements and will be capable of enlargement as the character and extent of the work of the institute may develop. Negotiations for a suitable plot are now under way.

A small hospital will also be built in the immediate future, which will be maintained in close association with the experimental work of the institute.

Provision will be made in the laboratory building for research in physiologic chemistry, pharmacology and therapeutics; in normal and pathologic physiology, and in various phases of morphology, and for the study of bacteria and other micro-organisms. It is hoped that the laboratory buildings may be completed and ready for the commencement of work in the autumn of 1904.

Dr. Simon Flexner, professor of pathology in the University of Pennsylvania, will direct the scientific work when the building is completed. His colleagues deem it of the highest importance that the institute has been able to secure so eminent an investigator as Dr. Flexner to shape the work of its early years. Dr. Flexner will spend several months abroad while the new buildings are in course of erection.

It is proposed to organize the various sections and departments into which the work of the institute will naturally fall so that each of them, though in a measure autonomous, will still be so closely associated as to favor the conjoint investigation of comprehensive problems. Associated with the head of each of these departments it is proposed to have a staff of trained assistants.

Provision will also be made for research work by a group of trained men, to be designated fellows, scholars, etc., of the institute, under pecuniary grants of varying amounts.

Finally, opportunity will be afforded to suitable investigators not members of the regular staff of the institute to pursue special lines of research.

The directors of the institute are: Drs. William H. Welch of Baltimore, Theobald Smith of Boston, Simon Flexner of Philadelphia, and Drs. Hermann M. Biggs, C. A. Herter, L. Emmett Holt, and T. Mitchell Prudden of New York.

The officers are: Dr. William H. Welch, president; Dr. T. Mitchell Prudden, vice-president; Dr. L. Emmett Holt, secretary, and Dr. C. A. Herter, treasurer.

Association News.

RATES TO NEW ORLEANS.

One Fare for Round Trip in Territory of Central and Western Passenger Associations Assured.

Central Association.

The Central Passenger Association has granted a rate of one fare for the round trip on lines in its territory en route to New Orleans and return. This territory comprises Indiana, Ohio, Michigan, a small portion of Pennsylvania and southern Illinois.

Western Association.

The Illinois Central Railroad has granted a rate of one fare for the round trip from all points on its lines. Mr. H. J. Phelps, city passenger agent, informs us of this arrangement, and says that some other roads in the Western Passenger Association have granted the same rate and that more will follow. The Illinois Central Railroad reaches Omaha, Minneapolis, Sioux City, Iowa, and Sioux Falls, S. D., and the precedent established by this road will doubtless be followed by roads covering the large territory of the Western Passenger Association, which extends to Canada and to the Rocky Mountains.

Trunk Line Association.

This association covers New York, Pennsylvania, West Virginia, New Jersey, Delaware, Maryland and part of Virginia, and authorizes the following rate:

> One first-class fare for the round trip from Washington, D. C.; and *from other points in Trunk Line territory* regular excursion fares to Washington or Trunk Line western termini added to one first-class fare authorized therefrom for the round trip; continuous passage tickets in each direction, to be sold and good, going, from Washington, D. C., May 1, 2, 3 and 4, and from other points May 1, 2 and 3, with final return limit to reach original starting point not later than ten days from date of sale, except by deposit of tickets by original purchaser with Joseph Richardson, special agent, Room 204, No. 204 Camp street, New Orleans, La., not earlier than May 1 nor later than May 12, between 8 a. m. and 8 p. m., and payment of fee of 50 cents at time of deposit, and extension of final return limit may be obtained to reach original starting point not later than May 30.

These conditions are in accord with the announcements in THE JOURNAL, Jan. 3 and 31, 1903, from the Southwestern Passenger Association.

Further particulars may be had from roads interested.

THE JOURNAL'S special New Orleans number, April 11, will contain a complete statement of railroad rates from all parts of the country, as announced last week, page 597.

Medical Organization.

Lexington (Ky.) Medical Society.

On January 14 this society disbanded and then reorganized, adopting the constitution and by-laws proposed by the American Medical Association for subordinate societies and re-electing Dr. James C. Carrick, president; Dr. Louis H. Mulligan, vice-president; Dr. George P. Sprague, secretary, and Dr. Francis M. Greene, treasurer.

Berrien County (Mich.) Medical Society.

At the regular meeting of this society at Benton Harbor, February 12, the national plan of reorganization presented at the January meeting was adopted. Dr. Edward J. Witt, St. Joseph, was elected president; Dr. Charles N. Sowers, Benton Harbor, vice-president; Dr. John D. Grecnamyer, Niles, secretary; and Dr. Frank M. Kerry, Benton Harbor, treasurer.

Dickinson-Iron County (Mich.) Medical Society.

Dr. Theodore A. Felch, Ishpeming, councilor of the twelfth district for the Michigan State Medical Society, organized this society at Iron Mountain, February 18, with the following officers: Dr. John D. Cameron, Iron Mountain, president; Dr. C. Frithiof Larson, Crystal Falls, vice-president, and Dr. Samuel E. Cruse, Iron Mountain, secretary and treasurer.

Brown County (Wis.) Medical Society.

The physicians of this county met at Green Bay, March 26, and organized a county society to become a branch of the Wisconsin State Medical Society on its reorganization. The following are the officers: President, Dr. B. C. Brett; vice-president, Dr. A. W. Slaughter; secretary, Dr. Walter J. Hagen; treasurer, Dr. J. R. Minahan; censors, Drs. H. A. Wolter, D. J. O'Connor and J. P. Lenfesty.

Drew County (Ark.) Medical Society.

District Councilor Dr. Vernon McCammon, Arkansas City, met the physicians of Drew County at Monticello, in October, 1902, and explained the plan for reorganization suggested by the American Medical Association. A constitution and by-laws in conformity with these suggestions were adopted, and Dr. William T. Stanley, Selma, was elected president; Dr. J. G. McKinney, Nelson, vice-president, and Dr. James R. Tarrant, Monticello, secretary and treasurer.

Macomb County (Mich.) Medical Society.

At a meeting of physicians of the county at Mount Clemens, February 24, Drs. Leartus Connor and Andrew P. Biddle, Detroit, and Dr. Oliver Stewart, Port Huron, were present as delegates from the Michigan State Medical Society. A society was organized on the lines suggested by the American Medical Association for county societies, and the following officers were elected: President, Dr. Philip A. Knight, Utica; vice-president, Dr. Robert L. Parkin, Romeo, and secretary and treasurer, Dr. Joseph M. Croman, Mount Clemens.

Societies.

Medical Society of Alexandria (Va.)—At the annual meeting, February 16, Dr. William M. Smith was elected president; Dr. William R. Purvis, vice-president; Dr. Hugh McGuire, secretary, and Dr. Thomas S. Gibson, treasurer.

Allegan County (Mich.) Medical Society.—At the annual meeting held in Allegan, January 28, Dr. Walter H. Bills, Allegan, was re-elected president; Dr. Milton Chase, Otsego, vice-president, and Dr. William S. Albright, Allegan, secretary and treasurer.

Medical Club of Philadelphia.—The election of officers, January 22, resulted as follows: Dr. Edward E. Montgomery, president; Drs. Roland G. Curtin and Jonathan C. Biddle, vice-presidents; Dr. Guy Hinsdale, secretary, and Dr. F. Savary Pearce, treasurer.

Champaign County (Ill.) Medical Society.—At the meeting, February 12, Dr. E. Fletcher Ingals, Chicago, delivered an address on "Medical Organization," which was freely discussed by the members. At the banquet which followed Dr. Ingals was the guest of honor.

Northeastern District (Mich.) Medical Society.—At the meeting of this society in St. Clair, January 29, Dr. Albert E. Thompson, St. Clair, was elected president; Dr. W. P. Dierck, Marysville, vice-president, and Dr. A. Henri Cote, Port Huron, secretary and treasurer.

Burt County (Neb.) Medical Society.—The physicians of the county met at Tekamah, February 11, and organized, with Dr. Andrew D. Nesbit, Tekamah, president; Dr. Mortimer L. Hildreth, Lyons, vice-president; and Dr. Isaiah Lukens, Tekamah, secretary and treasurer.

Nicollet County (Minn.) Medical Society.—At the annual meeting, January 19, at St. Peter, Dr. Harry A. Tomlinson was elected president; Dr. Jared W. Daniels, vice-president; Dr. Mary P. Hopkins, secretary, and Dr. Walter H. Darling, treasurer, all of St. Peter.

Barry County (Mich.) Medical Society.—The first annual meeting was held in Hastings, January 29, at which Dr. James M. Elliott, Hickory Corners, was elected president; Dr. Aleck F. Hutchinson, Nashville, vice-president, and Dr. J. G. McGuffin, Carlton Center, secretary and treasurer.

Eaton County (Mich.) Medical Society.—The annual meeting was held in Charlotte, February 5. Dr. Giles B.

Allen, Charlotte, was elected president; Dr. Mary E. Greene, Charlotte, vice-president; Dr. Warren H. Rand, Charlotte, secretary, and Dr. H. Allen Moyer, Chester, treasurer.

Medical Society of the State of New York.—At its annual meeting in Albany the following officers were elected: Dr. Algernon T. Bristow, Brooklyn, president; Dr. Edward B. Angell, Rochester, vice-president; Dr. Frederic C. Curtis, Albany, secretary, and Dr. Ogilvie D. Ball, Albany, treasurer.

Ulster County (N. Y.) Medical Association.—At the regular meeting in Kingston, February 16, Dr. Henry Van Hoevenberg, Kingston, was elected president; Dr. George S. La Moree, Highland, vice-president; Dr. Mary Gage-Day, Kingston, secretary, and Dr. Alice Divine, Ellenville, treasurer.

Adams County (Neb.) Medical Society.—The physicians of the county met at Hastings, January 31, and organized this society with an initial membership of 20. Dr. Winfield Ackley, Juniata, was elected president; Dr. Jay G. Roberts, Hastings, vice-president, and Dr. Marble, Hastings, secretary and treasurer.

Nemaha County (Neb.) Medical Society.—The physicians of the county met at Auburn, January 28, and organized a medical society, with the following officers: Dr. Ira H. Dillon, Auburn, president; Dr. Benjamin F. Lorance, Brock, vice-president, and Dr. William E. Shook, South Auburn, secretary and treasurer.

Monroe County (Mo.) Medical Society.—This society has been organized at Paris, with the following officers: President, Dr. Benjamin D. Dysart, Paris; vice-presidents, Drs. C. H. Dixon, Holliday, and A. I. Griffith, Stoutsville; Dr. William B. A. McNutt, Monroe City, secretary, and Dr. Fred M. Moss, Paris, treasurer.

Ogle County (Ill.) Medical Society.—At its annual meeting in Oregon, January 7, the following officers were elected: Dr. William W. Burns, Polo, president; Drs. James Parkhurst, Grand Detour, and Jesse C. Akins, Forreston, vice-presidents; Dr. Horace Sheets, Byron, secretary, and Dr. Leo E. Schneider, Oregon, treasurer.

Hall County (Neb.) Medical Society.—The physicians of Hall County met at Grand Island, and organized a society as a component branch of the proposed reorganized state society. Dr. George Roeder was elected president; Dr. Henry D. Boyden, vice-president, and Dr. C. J. Horton, secretary and treasurer, all of Grand Island.

Johnson County (Neb.) Medical Society.—The physicians of the county met recently at Tecumseh and organized a county society, with the following officers: President, Dr. Malcolm Stewart, Tecumseh; vice-president, Dr. Edwin T. Black, Cook; secretary, Dr. Carlton K. Chubbock, Tecumseh, and treasurer, Dr. George J. Rubelman, Tecumseh.

Buffalo County (Neb.) Medical Society.—In pursuance of the plans suggested by the Nebraska State Medical Society, the physicians of the county met in Kearney, February 20, and organized this society, with the following officers: President, Dr. Frank A. Packard, Kearney; vice-president, Dr. James W. Miller, Gibbon, and secretary and treasurer, Dr. George M. Hull, Kearney.

Livingston County (Mo.) Medical Society.—About twenty physicians of the county met in Chillicothe, January 31, and organized a county society, with the following officers: Dr. Rueben Barney, Chillicothe, president; Drs. William L. White, Spring Hill, and William A. Swope, Wheeling, vice-presidents; Dr. Arthur J. Simpson, Chillicothe, secretary, and Dr. Byron N. Stevens, Chillicothe, treasurer.

American Electro-Therapeutic Association.—At the twelfth annual meeting held at the Hotel Kaaterskill, N. Y., the following officers were elected: President, Dr. Daniel R. Brower, Chicago; vice-presidents, Drs. Maurice F. Pilgrim, and C. Frank Osman, Boston; secretary, Dr. Clarence E. Skinner, New Haven, Conn., and treasurer, Dr. Richard J. Nunn, Savannah, Ga. The next meeting will be held in Atlantic City, N. J., September 22, 23 and 24.

Champaign County (Ohio) Medical Society.—At the January 29 meeting, held in Urbana, Drs. Horace Bonner, Dayton, state councilor for the district, Brooks F. Beebe, Cincinnati, and Charles L. Minor, Springfield, presented arguments for reorganization on the plan outlined by the American Medical Association. At the annual election of officers, February 19, Dr. Samuel M. Mosgrove, Urbana, was re-elected president; Dr. Davis R. Emmons, North Lewisburg, vice-president; Dr. Edwin W. Ludlow, Urbana, secretary, and Dr. David O'Brine, Urbana, treasurer.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, held Feb. 16, 1903.

President, Dr. Alexander Lambert, in the Chair.

A New Method of Fixation of the Movable Kidney.

DR. W. GILL WYLIE commented on the relative frequency of movable kidney in women, and its frequent association with appendicitis, and cautioned the surgeon to make sure that it was really the kidney and not the appendix which was causing the pain. He considered that the effort so commonly made by surgeons to fix the kidney at the level of, or just below, the twelfth rib, as wrong in principle because of the fact that normally the kidney was not a fixed organ, but had a certain degree of mobility. He objected also to selecting this point for the anchorage of the kidney on the ground that if this were done the kidney would be pressed on by tight corsets and bands, thus causing discomfort. The object of his method of operating was to keep the kidney in good position and, at the same time, allow its moving slightly with respiration. The incision should be made just below the twelfth rib and the kidney replaced; then the capsule was pulled out with forceps until the resulting tension was sufficient to hold the kidney just above the twelfth rib and, at the same time, allow of the slight mobility normally possessed by this organ. Having cut away the redundant capsule, the ends were sutured to the fascial lining of the muscles about the opening by means of silk, and the muscles themselves were sewed with catgut.

Results of Kidney Fixation by Present Methods.

DR. A. B. JOHNSON gave a brief sketch of the common methods for anchoring the movable kidney. As regards suture material, his own preference was for catgut.

Discussion.

DR. J. A. BLAKE thought that failure to secure permanent fixation of the kidney often arose from a rotation of the organ by which it came to lie horizontally. He preferred catgut for the sutures, but thought it made little difference whether they were passed through the fatty or fibrous capsule, as they were only of service until granulations had formed.

DR. JOHN F. ERDMANN remarked that, while he employed kangaroo tendon for the sutures, this was not a matter of much importance, and that if the patient could be kept sufficiently quiet the sutures might be entirely dispensed with.

DR. A. H. GOELET condemned catgut as being too unreliable, and stated that his preference was for silk.

DR. E. W. LEE said that when catgut was treated with the Credé silver salts it became strong and could not be stretched. The method of operating which he advocated consisted in splitting the capsule, rolling the latter back on either side into a roll, and making use of the latter for securing a firm hold with the sutures.

CHICAGO NEUROLOGICAL SOCIETY.

Regular Meeting, held Jan. 22, 1903.

The Vice-President, Dr. H. H. Donaldson, in the Chair.

Nature of Neuroglia Tissue.

DR. G. CARL HUBER of the University of Michigan reported a study, extending over a series of years, of neuroglia tissue of different classes of vertebrates, made especially with Benda's sulpha-lizarate toluidin blue method. The research was undertaken with a view of harmonizing the various views expressed concerning the structure of neuroglia tissue and of obtaining data for experimental work. Tissue was studied from man, dog, cat, rabbit, dove, tortoise and frog.

The following general conclusions were reached: the neuroglia tissue of all vertebrates consists of neuroglia cells and neuroglia fibers. The cellular elements vary greatly in size and shape, depending in the main on the spaces which they occupy. In the majority of the neuroglia cells a granular cytoplasm can be clearly made out. This varies greatly in amount, at times forming only a narrow zone around the nucleus; again present in much larger quantity and presenting very distinct protoplasmic branches. In certain cells, which

are designated as "free nuclei," no distinct cytoplasmic covering can be seen. The nuclei of neuroglia cells vary in size, shape and structure. The majority of them may be spoken of as vesicular nuclei with chromatin in the form of a number of relatively large granules, variously disposed. Other nuclei, usually the smaller and smallest seen, present the appearance of compact masses of chromatin, taking the stain relatively deeply. Transition forms between these two varieties of nuclei may readily be made out. The neuroglia fibers show very definite relation to the neuroglia cells, being imbedded in the peripheral layer of their protoplasm. With the method used, whenever the preparation is properly differentiated, the neuroglia fibers could be traced through the protoplasm of neuroglia cells without interruption. In imperfectly differentiated preparations they often appeared as processes. The small, deeply-stained "free nuclei" and the free nuclei showing a vesicular structure show no definite relation to neuroglia fibers, and are looked on as undifferentiated and undeveloped neuroglia cells. Microscopic preparations substantiating the statements made were demonstrated.

Mesoblastic Origin of the Neuroglia Tissue.

Dr. Shinkishi Hatai, from the Neurological Laboratory of the University of Chicago, stated in preface that on examining cross sections of the central nervous system of the white rat and mouse, two kinds of nuclei, differently characterized, are easily recognized. One kind coincides in structure with that found in the nerve cells while the other resembles very much in size, shape and staining character, and in an internal structure, the nuclei found in the walls of the capillaries. These nuclei, so-called, are always surrounded by a small amount of cytoplasm. These facts led him to a systematic study of these structures in order to determine their origin within the central nervous system.

The tissues of new-born white rats and mice were fixed in Carnoy's mixture and the paraffin sections were stained with toluidin blue and erythrosin.

"One group of the nuclei, which resembles in structure as well as in shape those of the nerve cells, can be identified without difficulty as derived from the ectoblast. For convenience I called these nuclei Type 1. The identification of the other group of the nuclei, or Type 2, is, however, difficult since these nuclei have no similarity to the nuclei of the ectodermal derivatives. On examining the capillary wall, I noticed very frequently a nucleus projecting outward, and in some cases these nuclei were isolated from the capillary wall, but lay close to it. Between these two appearances, various intermediate stages could be easily found. In some cases, a tip of the nucleus is still attached to the capillary wall, while the rest of it has become separated. This appearance shows very plainly the migration of the nucleus from the capillary wall into the surrounding tissue. There is no danger of confusing these nuclei with those of the leucocytes which escape from the capillary wall and exhibit ameboid movements, since they differ from them both in structure and size; the former being very much larger than the latter. As soon as the nuclei are separated from the capillary wall they migrate away from the capillary."

Dr. Hatai thought there was no doubt that the nuclei called Type 2 were derived from the capillary wall and migrated away from it. "The identification of these nuclei, which have migrated from the capillary wall, with neuroglia nuclei, is difficult. Since it has been shown that a small amount of connective tissue is present in the central nervous system in both young and old animals, this connective tissue might have been formed by the nuclei which I am describing, but there is no evidence to support the view that this could occur. The large number of the nuclei which have migrated from the capillary walls suggests at once that some of the neuroglia tissue is supplied by these nuclei. This idea is favored by the fact that similar neuroglia nuclei to those migrated from the capillary wall or mesodermal in type, exist in the adult animal."

Dr. Hatai quoted Kuhne, Chittenden, Chavalier and other investigators and concluded "that the nuclei which migrate from the capillary wall into the central nervous system are one source of the neuroglia tissue. The reasons for this conclusion may be summarized as follows:

"1. The great number of these nuclei; 2, neurokeratin may be formed not only by the cytoplasm of the ectodermal cells, but also by the cytoplasm in mesodermal cells; 3, presence of the nuclei of mesodermal type in the central nervous system of the adult animal; 4, ordinary connective tissue nuclei present in the central nervous system are there in much smaller numbers than the nuclei which have migrated from the capillary walls; 5, there is no evidence that the neuroglia fibers stained by the modern neuroglia technics are of ectodermal origin only; 6, since the cytoplasm undergoes very easily morphologic and structural alterations while the nucleus is more resistant, it follows that the nuclei are the better indication of the genetic relationship of the cells; 7, Capobianco and Fragnito, who observed the nuclei which migrate from the meninges into the central nervous system and believe these nuclei form a part of the neuroglia tissue, were unable to trace the successive transformations of the former to the latter.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Chronic Diarrhea.

Lyon, according to an abstract in *Amer. Med.*, states that where there is lienteric diarrhea the food must be as easily digestible as possible. Where the secretion of pepsin is deficient the food should consist of pure milk and of starchy vegetables prepared with milk. If there is hypopepsia accompanied by dilatation and active fermentation the stomach should be washed out. The treatment should be directed toward stimulating the remaining healthy glands of the gastric mucous membrane and which will combat fermentation. The first indication may be met by the administration of sodium phosphate in 2-gram doses (gr. 30) in half a glass of hot water or hot vichy water before breakfast. The following may be substituted:

℞.	Sodii chloratis	℥iiss	10
	Syr. belladonnæ	℥i	30
	Aq. destil.	℥iv	120

M. Sig.: One dessertspoonful before each meal.

Small doses of sodium bicarbonate may also be given before meals. Massage to the stomach has produced very satisfactory results, acting as a tonic to the musculature, decreases stasis, which is a persistent cause of fermentation.

Constipation.

H. Surmont, in *Indian Med. Record*, recommends properly-selected food, which includes some of the coarser articles of diet, honey, cooked fruits, oranges and raisins. In the way of hydrotherapy he recommends cold water in the form of the abdominal douche with broken jets or cold compresses applied over the abdomen and covering them with waterproof cloth and over this a flannel bandage. These should be left in place for half an hour. Cold water should be drunk on rising and a cold enema occasionally.

Massage and Swedish gymnastics are to be employed in the treatment of atonic constipation. The faradic current is also of service. In the way of drugs he recommends psyllium seeds three teaspoonfuls a day, one after each meal, by placing them in a little fresh water and swallowing them. Linseed may be taken in the same manner in tablespoonful doses. The oils may be used, which are classified according to their action, as follows: Oil of sweet almonds, olive oil, castor oil. A teaspoonful of castor oil at bedtime gives, after a few days, good results. This may be given in capsule if necessary. If not sufficient to produce the results a teaspoonful may be given in

the morning. Calomel is of service as a cholagogue and should be given in small doses.

More trustworthy are those preparations which tend to produce muscular contraction of the intestinal coats. Among these preparations the author mentions cascara, senna, strychnia and ergot. His advice is to leave aloes, jalap and rhubarb alone. The latter especially increases the constipation after short amelioration. Strychnia should be given in doses of gr. 1/70 (.0009) three times a day. This may be alternated with cascara, the powder, extract or cascarin.

The following combination containing senna is recommended:

℞. Pulv. senna (washed in alcohol) 3iiss 10
Sulphuris sublim. 3i 4
Pulv. feniculi
Pulv. glycyrrhizæ, āā.....3ss 2
Pulv. sacchari 3i 4

M. Sig.: One teaspoonful every evening or every morning where patients are unusually susceptible to the drug.

Podophyllin and euonymin are also recommended as follows:

℞. Podophyllin .....gr. 1/3 02
Saponis q. s.

M. Ft. pil. No. i. Sig.: One or two daily.

℞. Euonymin .....gr. 3/4 05
Saponis q. s.

M. Ft. pil. No. i. Sig.: One or two daily.

The following points are emphasized by the author: Diet and hygiene must always take preference over treatment by drugs. Drugs should always be used in small doses, tonic, so as not to stimulate too much a feeble muscular contractibility. No drug should be continued too long; discontinue it for a time and return to it again so as to prevent the system getting accustomed to it.

Enemas may be employed. To eight ounces of water two level tablespoonfuls of salt may be added or three of brown sugar or honey or from two to four of glycerin. The time most suitable for absorption seems to be an hour after breakfast or dinner, when the stomach begins to empty itself, and thus aids peristalsis.

Stimulating enemas and suppositories should not be employed daily as a catarrh of the rectum or colon may be set up and prevent their further use. They are, however, of great service to those individuals who complain that they never have any desire to go to stool, and in whom constipation appears to be connected with a diminution of the sensibility of the rectum. These patients should be instructed also to go to the closet at a certain time each day.

Excessive Perspiration.

The following powder containing salicylic acid is recommended to relieve excessive sweating of any parts of the body:

℞. Pulv. acidi salicylici 3ii 8
Pulv. zinci carb. precip. 3ii 8
Pulv. magnesii ustæ 3iii 12
Pulv. amyli .....℥iiss 75

M. Sig.: Apply as a dusting powder.

Treatment of Buboes.

William A. Groat, in *N. Y. Med. Journal*, states that the treatment of buboes which show signs of suppuration, comprises rest in bed, removal of the exciting cause or inhibition of its virulence and local application to the inflamed gland. The patient must remain in a recumbent position, with light, non-stimulating liquid diet. One-tenth grain of calomel should be administered every hour until the bowels move freely, and subsequently salines should be given throughout the course of the disease. Calcium chlorid in three to five-grain doses should be given three times a day.

If acute gonorrhea is the cause the urethra should be irrigated two or three times a day, with at least two quarts of warm, normal salt solution followed by a weak solution of some of the organic silver compounds. Later the number of irrigations may be decreased to one daily, and the strength of the silver solution increased. All sores on the penis should be cauterized, and if secondary symptoms have appeared mercurials should be pushed.

Locally to the inflamed glands the following combination should be applied:

℞. Ichthyol 3i 4
Guaiacol 3ss 2
Ung. hydrarg. 3ss 2
Lanolini q. s. ad.....3v 20

M. Sig.: Apply thickly over the swollen glands, cover with gauze and a layer of cotton or cotton wool dressing.

C. D. Luckett, in the same periodical, recommends the following local application:

℞. Ung. hydrarg.
Ung. belladonnæ
Ichthyol
Lanolini, āā 3iv 15

M. Ft. unguentum. Sig.: Apply locally every other day until resolution is accomplished.

Joseph N. Weller recommends the application of the following:

℞. Tinct. opii .....℥i 30
Liq. plumbi subacet. dil. .....Oi 480

M. Apply locally on gauze saturated and place an ice bag over this compress.

When there is much induration the following is recommended:

℞. Iodi .....gr. v 30
Pot iodidi .....gr. xx 1 30
Lanolini .....℥i 30

M. Sig.: Apply locally.

The author has obtained good results by injecting the following into the diseased parts:

℞. Acidi carbol. 3iss 6
Aq. destil. q. s. ad.....℥i 30

M. Sig.: Inject a few drops of the solution into the gland at various points by means of the hypodermic syringe. These injections should be made once a day for three days. A good point he brings out is that this watery solution permeates the gland more thoroughly than the pure drug, which only cauterizes in a limited area.

In debilitated persons tonics containing iron, quinin and strychnin should be given. If there is suspicion of the trouble being tuberculous, guaiacol in doses of five minims should be given internally. Rest and elevation should be carried out in all cases until all of the acute inflammation has subsided.

Bromoform.

The following combination is recommended by Scoville in administering bromoform:

℞. Bromoformi 3ss 2
Tinct. tolutani 3i 4
Mucil. acaciæ 3ii 8
Syrupi simp. 3iv 15
Aq. menth. viridis q. s. ad.....℥ii 60

M. Place the mucilage in a bottle and add an equal volume of the syrup, then add the bromoform and tincture of tolu, shaking well after each addition.

The following formula is sometimes employed in administering bromoform:

℞. Bromoformi .....gtt. x 65
Alcoholis 3i 4
Syr. simp. 3iii 12
Aq. destil. .....℥iiiss 105

M. Sig.: One to two tablespoonfuls every hour.

Eclampsia.

Maygrier, in the *Med. Press*, states that as soon as the diagnosis of albuminuria is made every pregnant woman should be placed on a milk diet and put to bed. When eclampsia is diagnosed the first thing is to relieve the system of toxic principles and to calm the nervous excitability. The first indication is filled by blood-letting—withdrawing from ten to twelve ounces as rapidly as possible, followed by an injection of artificial serum equivalent in amount to the blood withdrawn. The agitation and excitability are best controlled by a few whiffs of chloroform and an enema of chloral. He does not recommend rapid delivery as the eclampsia could persist after delivery, and on the other hand pregnancy could continue after the attack. Only two complications could

warrant intervention: Anuria or a rise in temperature. Beyond these conditions the pregnancy should not be interrupted. If labor has set in then every means should be taken to perform rapid delivery.

Medicolegal.

Special Damages to Physician Which Must Be Pleaded.—What is entitled in the Court of Appeals of Kentucky "the case of the Louisville & Nashville Railroad Company vs. Reynolds" was brought to recover for personal injuries, by the latter party, who stated on the witness stand that he was a practicing physician, making a specialty of diseases of the eye, ear, nose and throat for something like thirty years. His allegation as to the damages was that he "was badly bruised and injured in his person, and his health and vitality permanently impaired, and his ability to walk with ease and comfort permanently and greatly decreased, and he was also caused great mental and physical suffering, and for a long time rendered incapable of attending to his business; whereby he has been damaged in the sum of $10,000, for which he prays judgment and all proper relief." For 17 or 18 days after his injury he was not able to sit up, and at the end of three months was not able to ride in a street car. The jury returned a verdict for $9,166.66, under an instruction allowing them to find, among other things, such an amount as would fairly and reasonably compensate him for the value of time lost. But the Court of Appeals holds that the petition in this case was not sufficient to admit evidence that he was injured during the best time of the year for his practice, when he earned something more than $100 per day. It says that the fact that this was the best season of the year for him in the practice of his specialty, and that the time he lost was so valuable, was not to be inferred from his injury, or the bare allegation that he lost time; and, to justify a recovery of items so unusual, the fact should have been specially pleaded. In other words, it applies the rule that where special damages are not such as the other party would naturally anticipate from the injury, they must be pleaded with sufficient particularity as fairly to apprise him of the charge which he is to meet.

Validity of Notes Given to Unlicensed Practitioners.—The Supreme Court of Nebraska holds, in the case of the Citizens' State Bank of Newman Grove vs. Nore, that a note given for medical services by an unlicensed practitioner may be recovered on by a bona fide purchaser, notwithstanding the provisions of article 1, chapter 55, of the Compiled Statutes, prohibiting the practice of medicine without a license. It says that in that state a statute will not be construed so as to make a negotiable instrument void in the hands of a bona fide purchaser unless the act specifically so declares. Article 1, chapter 55, of the Compiled Statutes of Nebraska makes it the duty of all persons desiring to practice "medicine, surgery or obstetrics" in that state to obtain a certificate from the state board of health, and to file the same with the clerk of the county in which they desire to practice. Section 15 provides: "No person shall recover in any court in this state any sum of money whatever for any medical, surgical or obstetrical services unless he shall have complied with the provisions of this act and is one of the persons authorized by this act to be registered as a physician." Section 7 declares it to be unlawful for any person to practice in any of these lines without first obtaining and registering such certificate; and section 16 makes it a misdemeanor to so practice, and imposes a fine therefor. It will be seen, the commissioners say, after thus summarizing the legislation invoked in this case, that none of these provisions declares a contract for medical services by an unlicensed practitioner to be void. Indeed, while section 15 provides that "no person shall recover," the latter part of the section indicates that this prohibition is limited to the practitioner himself. Again, they say that they fully recognize the importance of such legislation as the medical act. It embodies a fixed and time-honored policy of the most vital concern to the state and its people. But it may well be questioned whether the evils consequent on the free circulation of the notes given for services of unlicensed practitioners could be more serious than the derangement of business resulting from a rule that would make all such notes void in the hands of innocent purchasers. It must be remembered that instruments like these have no earmarks and, when once it is understood that a limited and indistinguishable class of them is deprived of the virtues of negotiability, a step is taken toward casting the taint of suspicion on all.

Liability for Necessaries Furnished the Quarantined.—A Texas statute provides that: "Whenever the commissioners' court of any county has reason to believe that they are threatened at any point or place within or without the county limits with the introduction or dissemination of a dangerous, contagious or infectious disease that can and shall be guarded against by quarantine, they may direct their county physician to declare and maintain said quarantine against any and all such dangerous diseases; to establish, maintain and supply stations or camps for those held in quarantine; to provide hospitals, tents or pest houses for those sick of contagious and infectious disease; to furnish provisions, medicine and all other things absolutely essential for the comfort of the well and the convalescence of the sick. The county physician shall keep an itemized account of all lawful expenses incurred by local quarantine, and his county shall assume and pay them as other claims against the county are paid." The Court of Civil Appeals of Texas holds, King County vs. Mitchell, that a proper interpretation of this statute would require that a county whose commissioners' court has determined that they are threatened with the introduction or dissemination of a dangerous, contagious, or infectious disease, that can and should be guarded against by quarantine, and has directed the county physician to declare and maintain such quarantine, should furnish to those thus detained such provisions, medicines and other things as are absolutely essential to their comfort and convalescence, and is legally liable therefor. It can not hold, it says, that it is optional with a county to assume the duty of supplying these things. Nor can it assent to the contention that the county would be relieved of this duty because of the fact that there was no county physician to keep the itemized account of the expenses incident to the quarantine after the county physician had resigned. The beneficial purpose of the statute was to supply to those detained in quarantine such things as were absolutely essential to their comfort and convalescence, and the duty of the county physician in the particular of keeping an itemized account of expenditures is, at most, only ministerial in its nature, and the liability of the county not made to depend on his compliance. If such were the case, the county could in the most meritorious cases avoid all liability by refusing to appoint such auditing officer. Further, it was the duty of the county judge to appoint another physician on the resignation of the county physician referred to. Here the county made an order directing a quarantine, appointed a county physician, who established such quarantine, placing guards, etc., knew of the resignation of the county physician, and continued thereafter to maintain such quarantine, without providing another, and without in any manner providing for the wants and necessities of those thus affected by the order and, the court holds, must be held to have consented to the party suing supplying such things as it was legally liable for, but which it had made no arrangements to supply. However, such an account, the court holds, could not be treated as a verified one under the state statute requiring denial by affidavit before trial if to be disputed. To treat it as such an account, and to deny the right of cross-examination as to the correctness or reasonableness of the items sued for, the court says was material error, for it was certainly pertinent to inquire into the correctness and reasonableness of the items, to the end that the county be not held liable save in the event the "provisions, medicine and other things" appeared to be "absolutely essential for the comfort of the well and the convalescence of the sick," considering the nature and extent of the quarantine.

8 The Importance of Mechanical Manual Training to the Surgical Student. S. D. Van Meter.

1. **Chronic Pancreatitis.**—This disorder was first described in 1896, but has been fully understood only within the last eighteen months. Hardin reports a case and discusses the anatomy, etiology, etc. He thinks the cause is obstruction due to calculi lodged in the pancreatic duct, pressure from gallstones, infection by micro-organisms, or to toxic substances in the blood. The symptoms are severe hypogastric pain, central in situation, nausea and vomiting, jaundice, diarrhea or constipation, undigested muscle fiber in the dejecta and in rare cases lipuria. In advanced cases glycosuria occurs. The diagnosis is difficult. The presence of undigested muscle fiber in the stools and the absence of carbolic acid in the urine after the administration of salol are good tests, but we must base the diagnosis mainly on jaundice, paroxysmal epigastric pain, midepigastric tenderness and resistance, rapid loss of flesh and strength with absence of marked anemia and leucocytosis, the presence of undigested muscle fiber and the peculiar reaction of the urine to the phenylhydrazin test. In many cases exploratory operation should be done. The disease may be a chronic one, but early operation generally gives good results and mortality will be practically nil. If sugar is found in the urine the prognosis is unfavorable for it means that the pancreas is pretty nearly destroyed.

2. **Tuberculosis.**—The experiences at the Muskoka Cottage Sanatorium for the treatment of tuberculosis are reviewed by Elliott, who reports very favorable results.

3. **Morphin.**—Crothers pleads against the careless use and prescription of morphin as causing the morphin habit.

4. **The Gastric Test.**—Benedict gives details of the examination of the stomach contents after the test meal, using bread and butter for the simple test meal, and allowing one and one-fourth hours. In a meal containing meat and vegetables, one and one-half to two hours. He prefers the use of the large tube to bring out the contents. The various tests for acidity, carbohydrates, bile, proteids, etc., are described, as well as the microscopic findings. He remarks that it is worse than looking for a needle in a haystack to attempt to diagnose ulcer, cancer, catarrh, etc., from the microscopic examination. For any serious investigation with regard to these points the jejune stomach should be washed out. Scraps of exfoliated gastric epithelium are practically always found. Setting aside cancer and ulcer it is exceedingly difficult to distinguish between the normal shedding of epithelium and the indications of genuine gastritis. He says he is disposed to think that almost every stomach is almost constantly in a state of localized catarrh.

5. **Physical Exercise.**—In this first article Lydston speaks of the mistakes that have been made in prescribing exercises in a routine way, leading to such measures as advising postmen to take walks or gripmen to indulge in free exercise in the open air. There should be a department of physical training attached to the chair of therapeutics in every modern medical school. The value of a knowledge of physical training in the special departments such as neurology and surgery, especially orthopedic surgery, is obvious..

6. **Gonorrhea in Children.**—Lowenburg reports a case in a four-year-old child who probably infected himself by his hands as he was in the habit of handling rags and clothes from the refuse boxes. The lesson which the case teaches, he says, is:

1. All urethral discharges in young boys should be viewed with suspicion.
2. All such discharges should be submitted to a microscopic examination.
3. Should the gonococcus be found the possibility of the case assuming a medicolegal nature should be remembered.
4. The question of rape should be carefully eliminated or conclusively proved.
5. Treatment consists in securing local cleanliness and a free action of the emunctories in conjunction with the administration of urinary antiseptics and alkalies.
6. Gonorrhea is no contraindication to circumcision.
7. Vulvovaginitis in little girls is very often due to gonorrhea.

7. **Vital Statistics.**—In the conclusion of his article, Fulton insists on the importance of thorough local registration covering:

1. Records of death made at the time and place of their occurrence, by the most competent persons acquainted with the facts, including a medical certification of the cause of death, the making and filing of such a record being in every instance an indispensable preliminary to the disposal of the dead body; 2, records of birth, secured by the payment of fees, by every appeal to private interest and public necessity, including, if possible, conditioning of certain privileges of citizenship on recorded evidence of attained age; 3, records of marriage and divorce, with all such items of information as have statistical importance; 4, records of sickness, including all cases of those infectious diseases which fall within the provisions of the notification laws, all cases of sickness which come under study in the public health laboratories, all sickness which is relieved at public cost, all sickness falling under the observation of inspectors of schools, tenements and factories, and all sickness occurring in the public services, *e. g.*, Army, Navy, police, and fire departments.

Finally, the data of vital statistics should be systematically utilized, not only for the broader purposes which have grown into common use, but for the minuter inquiries which such records may answer.

14 *Empyema of the Accessory Sinuses of the Nose. J. H. Woodward.
15 A New Sputum Slide. James R. Arnell.

11. **Functional Disorders of the Liver.**—These conditions which may be included under the head of morbid excess, morbid deficiency and a vitiation of the bile, are noted by Richardson. He remarks that a considerable percentage of the population is more or less affected by gallstones, judging from the Johns Hopkins autopsy reports, about 7.5 per cent. in this country. The surgeon seems to have the monopoly of treatment of these conditions, but he still thinks much may be done with drugs. He speaks particularly of the use of glycocholate of soda.

12. **Tuberculosis.**—Heitzman briefly reviews the general facts in regard to the treatment of tuberculosis and concludes that the hope for the future is in hematotherapy and serumtherapy.

13. **The Internal Saphenous Vein.**—From a number of experiments performed on 50 subjects, Campbell finds a considerable variation in the tributaries of the internal saphenous, and that the proper point in which to ligate is that portion of the vein which lies between its last tributary and the saphenous opening. This space is about ¾ of an inch in length, varying somewhat in different subjects. A circle about the size of a five-cent piece ought to fix the limits within which we can expose this portion of the vessel. The author found that the end of a line, 3½ inches long, projected from the spine of the pubes at right angles to Poupart's ligament, will always fall within this circle. The end of this line marks the point for the center of the incision, which should be about one inch long and parallel with the fold of the groin. In retracting the edges of the incision, retract the upper edge so as to ligate as near the saphenous opening as possible.

14. **Empyema of the Accessory Sinuses of the Nose.**—Woodward describes the various conditions of suppuration in the accessory sinuses in which he includes the ethmoidal cells. In view of the variations in the size and position of the frontal sinus he gives the following rule:

Almost without exception, when they exist at all, the frontal sinuses will be found immediately underneath the triangles constructed as follows: Connect the supra-orbital foramina or notches by a horizontal line, drop from its mid-point a vertical to the fronto-nasal suture, and complete the triangles by lines drawn from the naso-frontal end of the latter to each respective supra-orbital foramen. Thus two triangles are constructed above the root of the nose, through which even the smallest sinus may be opened. The anterior wall of the sinus may be 8 mm. in thickness, although, as a rule, it is very much thinner. In operating through the anterior wall of the sinus, our course should be directly backward. If, however, we have traversed in this direction 8 mm. of bone without opening the sinus, it would be wise to change the course of the excavation to downward, backward, and inward, toward the uvula. Thus, opening the anterior cranial fossa may be avoided, while our explorations would expose even the smallest sinus, or, in the absence of the sinus, open into the anterior ethmoid cells.

He prefers to approach the frontal sinus through the anterior wall as it gives a chance for more thorough treatment. To reach the maxillary antrum he would prefer an opening high up in the soft parts under the upper lip, which will remain open long enough for lavage and drainage. It is not advisable in his experience to irrigate the antrum even with the mildest solution for a longer period than four or five weeks. Irritating antiseptics should never be used. If, after treatment, pus formation is marked a large opening for drainage may be cut in the wall of the inferior meatus and the sinus irrigated as circumstances require. Of course the obstruction in the nose should be removed as a preliminary treatment. Suppuration in the ethmoidal cells he attacks preferably by the intranasal route. They may be opened through the ethmoidal sinus and through the orbit, but only when there is complicating sinusitis or orbital abscess and even then the intranasal operation should still be performed. The sphenoidal sinus should be approached through the intranasal route after removal of the middle turbinated bone.

19 Pyemia and Exsection of Part of the Lower Jaw Following a Fracture Due to Tooth Extraction. J. A. Hofheimer.
20 *The Prophylaxis of Appendicitis. H. Illoway.

16. **Tuberculosis.**—Wright reviews the literature of the transmission of animal tuberculosis to man. He questions the possibility of this, holding that Koch's paper has done a great deal of good, though his views are not original. The inhalation of bacteria is also studied and he finds both from his own studies and the recent work on the subject by Saenger that the bacteria can not penetrate very well to the alveolar regions by inhalation. He suggests a discussion of the diagnosis of tuberculosis, which is probably often erroneous. Influenzal hemorrhages sometimes simulate early tuberculosis, as suggested by Donelan. The laryngeal and pharyngeal forms of tuberculosis and their curability are also discussed at some length. In conclusion he speaks of the serum cure, which from reports has a rather encouraging prospect. He suggests that if we could form the habit of going to Germany for our facts and to England for our deductions, we should in the former find a more abundant harvest, and in the latter a more trustworthy separation of the wheat from the chaff.

17. **Pulmonary Anesthesia.**—Bryan says that the paralysis of respiration due to forcing the anesthetic and the crowding of blood in the right heart which occasionally occurs during the second stage, may cause distension beyond the power of contraction, and death ensues. He suggests that the means to prevent the second stage of struggling in anesthesia are ample and the co-operation of the patient can often be usefully employed. A patient at the beginning of anesthesia had to be held by four men; he was released and told to clasp his hands. He immediately became quiet and did not move again until he came out of the anesthetic. Death may occur from paralysis of the heart from over-dosage and from the operation, especially in the region of the fifth nerve. Care on the part of the anesthetist can prevent either of these accidents. These statements are especially applicable to chloroform. Death may occur instantaneously from paralysis of the heart during complete anesthesia; from damming of the blood in the right heart at a stage when it is preventable, and from paralysis of the heart due to operative interference in incomplete anesthesia; from obstruction of the respiratory passages, causing asphyxia, and from the combined shock of anesthesia and operation. In the last two cases it is usually preventable. In impaired respiration or heart function, the rule is to lower the head to allow a freer flow of blood to the brain and the heart, but where an intra-abdominal obstruction to diaphragmatic function is causative of the symptoms, as in abdominal tumors, the only course is to elevate the head and relieve the pressure of the tumor on the heart. When conjunctival reflexes are gone, we are reasonably certain of surgical anesthesia. On giving too much or too little of the anesthetic, particularly ether, the pupil dilates. The question is whether this dilation is a danger signal or a sign of too little anesthesia. He says close the eye, open it again in the presence of light; if the pupil reacts to light, the patient is safe and more ether can be given; if the pupil will not respond to light too much ether has been given, and we must wait for the pupil to respond. Under complete anesthesia, when the steady, straightforward stare of the eyes is supplanted by a nystagmus, it means the patient is coming out from under the drug and needs another dose. In surgical anesthesia, respiration is regular, full and stertorous. A deep sighing respiration nearly always precedes the appearance of reflexes and should be recognized as their forerunner. The general circulation should be watched in all cases as an index to the condition of the blood and heart. He speaks in conclusion of chlorid of ethyl as a valuable anesthetic, being quicker in action with a quicker return of consciousness. He ranks danger as regards mortality as: 1. Chloroform; 2, ether; 3, ethyl chlorid, and fourth, nitrous oxid. He gives ethyl chlorid through a tight-closed cone that allows a spray of the liquid to run on a piece of gauze, over which all the inhaled air must pass, and containing an outlet valve, so as not to permit waste by expiring through the same opening. This agent is peculiar in that not every case is completely relaxed by it, and ocular reflexes are not always destroyed, but otherwise the anesthesia is complete.

20. **Appendicitis.**—Illoway considers constipation the principal factor and one much more common than is generally recognized, the patients themselves not estimating their own condition properly.

21 *The Treatment and Care of Consumptives at Their Homes, and the Urgent Need of Local Sanatoria. S. A. Knopf.
22 *The Present Status of Surgery of the Gall Bladder and Bile Ducts. William J. Mayo.
23 *Post-operative Malaria, with a Report of Two Cases. John T. Moore.
24 *Trachoma in the Public Schools of New York. Walter E. Lambert.

21. **The Home Treatment of Consumption.**—Knopf gives a description of appliances for the care of the sputa, directions for the care of the patient, use of light, air and hydrotherapy and pleads for the establishment of a sanatorium in the neighborhood of every large city.

22. **Gall Bladder Surgery.**—The percentage of latent gallstones commonly accepted is held by Mayo as probably too high, and he asks the question what causes latent calculi to become active. Remarking on the theory of Kehr, who attributes everything to infection, and the other more generally adopted one of mechanical interference with drainage, he thinks both have their share. He compares the condition with appendicitis, which may have its alternations of aggravation and rest. In some cases the results of early operation for gallstone disease are remarkably good. The death rate under his hands was less than 1 per cent. In the later stages, however, after repeated attacks of biliary colic, with adhesions and general infection of the parts, the condition is different and operation is fraught with some danger. It is in this class of cases that cancer of the gall bladder is most likely to occur. In 49 of his cases stones were found in the common and hepatic ducts, with or without jaundice, but in any event necessitating a very serious operation. Infection of the liver ducts introduces a serious element in the prognosis. Most deaths after operation he attributes to this cause.

23. **Post-Operative Malaria.**—The revival of malaria after operations or injuries, which is a matter of common faith among physicians of malarial districts, has been denied, but Moore here reports two cases, which he thinks prove the correctness of the belief. He suggests a blood examination by the microscope in every case from a malarial locality before operation, and says that many infections which have lain dormant for weeks, months and even years may be rekindled. Malarial fever, especially the chronic forms, brings out a very unfavorable condition for the healing of wounds and the reaction from the shock of the anesthesia and operation. It is reasonable to suppose, he holds, that many cases of fatality after operation are due to the presence of the malarial parasite.

24. **Trachoma.**—The conditions in the New York schools are reviewed by Lambert, who believes in thorough inspection and a special hospital for the treatment of all contagious eye diseases in New York City. It would be important, of course, to have the inspectors thoroughly competent men, who will examine the upper as well as the lower cul-de-sac of the eye.

25 *Observations on Long-Distance Runners. J. B. Blake and R. C. Larrabee.—The Blood. Ralph C. Larrabee, Wilder Tileston and Wm. R. P. Emerson.—The Hearts. Ralph C. Larrabee and Lawrence W. Strong.—Kidneys. John M. Connolly.

26 *Medical Treatment of Intestinal Obstruction. Thomas F. Harrington.

25. **Long-Distance Runners.**—This subject takes up most of this issue and includes general observations as to the condition of the runners, pulse, weight, temperature, condition of the blood, heart, kidneys and physical characteristics. The distance run was about twenty-four miles over a more or less hilly country. The effects seem to have been largely physiologic; pathologic conditions were not noted. So far as known none suffered serious or permanent harm from the race. The heart changes seemed to be physiologic. The article is an interesting study.

26. **Intestinal Obstruction.**—The different forms of intestinal obstruction and their non-surgical treatment are described by Harrington. In cases where foreign bodies have been swallowed, he advises against castor oil administration, but to give food that will produce bowel evacuation. Examine the rectum frequently as the foreign body often lodges there. In intussusception he thinks it best to chloroform the child, lay it on its back, and slowly inject one or two gallons of warm water into the rectum. He remarks that the rectum is capable of holding 6 quarts (?). Large enemata should always be tried before advising surgical interference. He thinks the experience with exploratory laparotomy offers little to endorse this short road to knowledge. The article is one that rather depreciates the value of surgery in these cases.

31 *Retinal Hemorrhages: An Aid to the Early Recognition of General Arterial Degeneration. Henry C. Haden.

27. **Tropical Diseases.**—This fifth lecture by Kieffer is devoted to abscess of the liver and more especially to tropical abscess, which is in the vast majority of cases due to the *Ameba dysenteriæ*. Predisposing causes, however, are necessary. These are usually found in the free living, both as to alcoholic beverages and food, but especially the former. The natives are quite as liable to it as the Europeans if they follow the same habits of diet and drinking. European women and children are, as a rule, free from this complication. There is a small group not due to this cause, but to the *Balantidium coli*, and the various pyogenic organisms may have their causal action. Cantlie holds that all intrahepatic abscesses are amebic, and that the so-called "idiopathic abscesses" are suprahepatic, or subhepatic, that is, abscesses of the dome or concavity. The symptoms may be obscure; hectic range of temperature, liver enlargement, sense of weight and fulness, occasionally deformity, pain especially in the right shoulder and occasionally a sharp pain in the esophagus in swallowing, while a hacking unproductive cough may be present. There is characteristic decubitus; the patient lies well over on his right side with the shoulder drawn down and the knee drawn up. Jaundice is rare. Ascites only occurs when the abscess presses on the portal vein, which is of some importance in the operative treatment. The old-fashioned way of leaving the abscess to "determine its own direction" is condemned; the "determined" spot is usually a grave. The proper method is to operate; 90 per cent. of cases of single abscess operated on fairly early recovered. If spontaneous rupture occurs into the colon, about one-half recover; rupture elsewhere is not nearly so favorable. The diagnosis is difficult. The common mistake is to call the condition malaria, but he points out the differences, especially the character of the fever, occurring at or near the same hour every day, which is clearly not malaria. In all obscure cases, he says, attended with signs of sepsis, insert an aspirator to make the diagnosis sure. Leucocytosis is of some importance. It may be absent, but its presence is corroborative. Sometimes the abscess may be intimately connected with the parietes, though it is difficult to be sure as to locality. Usually when the liver is punctured, respiratory excursion gives a pendulum-like movement of the needle. In this class of cases this movement may be absent. The treatment will be discussed in a coming lecture.

28. **Toxemia of Pregnancy.**—The theory of convulsive seizures of eclamptic or pregnant women is coming to be that they are due to a general toxic state of the blood, instead of being so exclusively a kidney affection as was formerly held. Wells has had opportunity to note the effect on pregnant women of stomach and intestinal catarrh following influenza. He thinks these are often the predisposing cause of what seems to be a rather resistant form of toxemia. Most of the cases occur in full-blooded rather than in anemic women. The symptoms are generally headache, pain and soreness about the eyes, occasionally photophobia, a dull and heavy feeling, sensitiveness to changes of weather, frequent urination with less than normal quantity, a sort of pyrosis, occasional nausea and edema. He describes several cases and remarks that the symptoms are quite different from those usually described in text-books, except those of recent date. The first case briefly mentioned is one in which the kidneys seemed to be suffering most, with albumin and casts, mental dulness with general symptoms pointing to uremia. The second type, of which several cases are reported, presents symptoms of chronic gastro-intestinal catarrh, but with a urine characteristic of toxemia. He holds that in the excretion of urea we have the most valid index of solid excretion. This is never as great in amount in the pregnant as in the non-pregnant condition, and an increase in the toxic symptoms is almost invariably preceded by decrease in the urea percentage. It is impossible to lay too much stress on the value of clinical study of the urine of pregnant patients. He always looks with suspicion on any headache, nausea or indigestion in pregnant women and instructs them to report at once if they have any of these symptoms. The pathology is noted—changes in the kidney, heart, liver and brain.

29. **Carcinoma of the Uterus.**—Hopkins finds the combined light and *x*-ray treatment of special advantage in uterine cancer and describes the arrangement which he has made for securing it. He would give about an hour's exposure to the Finsen light and about five or eight minutes to the *x*-ray as a treatment. This has given good results.

31. **Retinal Hemorrhages.**—With a report of two cases of retinal hemorrhage and remarks on the importance of the symptoms, Haden concludes as follows:

1. Retinal hemorrhages, associated with high arterial tension and accompanied by transitory albuminuria, are significant of beginning widespread arterial degeneration.

2. That in those cases of so-called physiological or transitory albuminuria, occurring in active, healthy young business men or students, in those who are working under forced pressure, ophthalmoscopical examination should be made for retinal hemorrhages.

3. When retinal hemorrhages occur without albuminuria, the patient should be kept under observation, the urine to be examined from time to time and the quantity passed noted.
4. In case of finding these conditions, it is our duty to warn the patient of his condition, and, as Osler says, "so gain his intelligent co-operation," and preserve his life and usefulness.

46 *Thoughts on the Prophylaxis of Puerperal Eclampsia. Douglas H. Stewart.

38. **Ureterovesical Grafting.**—Bissell's method consists in finding the ureter through an incision in the anterior surface of the broad ligament, and a dissection downward between the broad ligament folds, passing the forceps through the urethra into the bladder and up to the posterior vesical wall just below the junction of the broad ligament and the bladder, then incising the bladder between the blades and dragging the ureter through and anchoring it with an intestinal silk suture. He claims this method is most direct, admits of extraperitoneal manipulation and extraperitoneal implantation at the point of selection of the bladder wall; shifts the ureter but slightly from its normal direction, and allows thorough provision for leakage through the vagina at the base of the extraperitoneal space within the folds of the broad ligament.

40. **Retro-Uterine Displacement.**—The method here described by Noble is, in brief, the intramural extraperitoneal implantation of the round ligaments. Through a transverse incision in the lower abdomen the round ligament loops are brought forward and the ends fastened together, if long enough to meet on the median line, in front of the recti muscles. He has thus anchored the uterus 67 times and claims many advantages for the operation: a single incision through which pelvic complications may also be treated; the strong uterine end of the ligament is utilized; there is no vesical irritation or dysuria or interference with the normal mobility of the uterus, no sutures in the fundus to irritate the uterus, absence of tendency to hernia, no encroachment of the bladder or abnormal shortening of the ligament, and the fixation is extraperitoneal. The danger of operation, he thinks, is about equal to that of exploratory abdominal incision.

45. **Difficult Breech Presentations.**—This article considers only those cases in which one is confronted by a difficult, but not impossible, breech presentation. Such is most often seen in primiparæ, where the child is disproportionately large because the mother's pelvis is slightly contracted or the child is unusually large; it may also occur in any case where the cervix, vagina, and perineum are unyielding; or even in multiparæ when the child is disproportionately large. It includes original breech presentations, and those changed into breech by version. Labor is allowed to progress as usual until the breech is nearly to the pelvic floor; that is, until the child is sitting on the recto-vaginal septum. The patient is placed in the dorsal position and anesthetized profoundly. The child is then pushed carefully upward and both feet brought down, the possession of both feet giving the operator better control of the child. With the child's thighs in the cervix, dilate with the hand until the cervix is practically paralyzed; meanwhile dilate the vulvar orifice and vagina fully with the hand and closed fist, the success of this method being dependent on the thoroughness of the dilatations. During these dilatations gradually withdraw the chloroform. See that the cord is out of the way. Grasp the feet and draw the child slowly down until the umbilicus is nearly to the mother's vulva, while the assistant, or operator's own hand, if necessary, keeps the head well flexed so as to avoid extension and consequent catching at the pelvic brim. The operator then makes strong traction while the assistant presses down on the head firmly; if the woman is sufficiently aroused from the anesthetic, instruct her to expel the child with all her strength. The head then passes down the parturient canal, escaping the grasp of the cervix uteri, a little rotation of the child's hips, or side-to-side pull, serving to deliver the child to the shoulders. The arms and shoulders are then quickly delivered, delivering the posterior arm first, then rotating and delivering opposite arm (following the method well described on page 786 in Hurst's Obstetrics, 3d edition). The assistant then takes the child while the operator quickly delivers the head with forceps. The advantages of this method are: 1, the time of the labor is shortened; 2, there is little or no laceration of the mother, and 3, the child is neither strangulated nor mutilated because of being caught by the cervix or perineum.

46. **Puerperal Eclampsia.**—The treatment advised by Stewart is avoidance of noise, excitement and alarm, using hot packs to excite perspiration, frequent small venesections if necessary. He also notices the possible advantages of using irrigations of normal salt solution. We should carefully lower the amount of nitrogen in the food and increase the aggregate of its discharge, and in this way we have gone a long way in the prophylaxis of the condition.

54. **The Radical Cure of Aneurism.**—Matas describes in detail the methods of treatment of aneurism, with illustrations, and in conclusion submits in substance the following conclusions: 1. That the recognized advantages of the radical operation for the cure of aneurisms in the peripheral arteries as shown by recent statistics, can be greatly increased. The sphere of the operation can be broadened by the adoption of the method of suture and obliteration of the sac instead of the classic ligation of the arteries, with or without extirpation, as hitherto practiced. 2. That the closure of the arterial orifices which supply the aneurismal sac, whether single or multiple,

by means of suture, and within the sac itself, greatly simplifies the technic of the radical operation and is a reliable means of securing hemostasis. 3. That in favorable cases such as saccular aneurisms with a single orifice communicating with the lumen of the larger arterial trunks, it is possible by careful suture to obliterate the aneurismal opening without obstructing the lumen of the parent artery, thus lessening the risk of gangrene. 4. It is also possible in favorable cases of fusiform aneurisms of traumatic origin, and in those in which the sac material is pliable and healthy, to restore the lost continuity of the artery by building a channel which will connect the two main orifices of communication and restore the interrupted circulation in the parent vessel. This can be done by utilizing the sac in the manner described by the author. 5. The fear that atheroma and other degenerative changes will interfere with the healing and repair of the arterial tunics has been greatly exaggerated, as shown by abundant experience of the aseptic period in the ligature of sclerotic arteries in continuity, in the absence of secondary hemorrhages in the amputated stumps of the aged, diabetic, and other arterially diseased subjects, and is still more fully demonstrated by the statistics of Delbet, Kubler, Ransohoff and others who have reported numerous successful results in spontaneous as well as in traumatic aneurisms. 6. The fallacy and dangers of the old operation of Antyllus lie, first, in the fact that the preliminary ligation of the main artery above and below the sac does not always control collateral bleeding, hence compels a more or less extensive dissection of the sac out of its bed as one of the necessary features of the procedure to include all the collateral vessels; the difficulties of the operation are increased and the vitality of the limb is endangered by interfering with the collateral circulation. Another serious objection to the old Antyllian operation is that the sac is allowed to remain as an open cavity in the bottom of the wound, where it is packed or drained and allowed to heal by granulation, thus inviting infection, suppuration and secondary hemorrhage. All this is obviated by the author's method of endoaneurismorrhaphy, which does not disturb the sac from its vascular connections and favors its prompt obliteration by suturing the infolded walls of the sac, and keeping them in direct and close approximation. 7. The dangers and uncertainties of extirpation of the sac are often more apparent because, in addition to the technical difficulties, there is the great risk of injury to the accompanying satellite veins and nerves which blend most intimately with the sac and often compel the surgeon to make his operation a partial one. The greatest objection, however, is in the interference with the collateral circulation, which entails a considerable risk of mortification in the distal parts. All these dangers are reduced to a safe minimum, and are largely eliminated by simply obliterating the sac, instead of extirpating it.

55. **Abdominal Contusions.**—Brewer notes the possibilities of abdominal contusions in the way of rupture of the viscera, liver, spleen, bladder, etc., and considers that in the earliest stages of abdominal injury, pain, tenderness and muscle rigidity are the most prominent and reliable signs. Their association is almost pathognomonic of peritoneal irritation. In the absence of spontaneous pain, localized tenderness with rigidity is strongly suggestive of visceral injury. Muscular rigidity, however, is the most reliable and sometimes the only sign. Spasm of one or more of the abdominal muscles following a traumatism may be looked on as Nature's efforts to protect the injured organ from further irritation. Vomiting is occasionally present, but is not always an accompaniment. The occurrence of free fluid in the peritoneal cavity, shown by the different percussion signs in different positions, is valuable. The presence of a large amount of fluid feces in the colon may rarely lead to error. Their specialized diagnosis, Brewer considers, is rarely possible. He reports a number of cases illustrating the points which he has brought out. He favors the treatment of extensive fractures of the spleen by pressure and gauze packing rather than by splenectomy. This is also applicable to the liver. It gives less shock, saves time and preserves an important organ. Speed of operation, perfection of technic and the ability to administer at any moment the most vigorous stimulants are the most important requisites of success. The assistants should be prepared to give saline infusions at the time the peritoneal cavity is opened.

58. **Injuries to the Spine.**—Oliver holds that it is proven that complete transverse lesion of the cord is hopeless, and asks if a correct diagnosis of such can be made. He reports cases as showing the utility and effects of operation. On the whole, his opinion seems to be favorable to delay in operating in cases of spinal injuries. It gives them a chance for spontaneous recovery or improvement.

60 Dr. Lorenz's Clinic in New York, December 18, 1902. Charles E. Davis.
61 *Infantile Diabetes Mellitus. Howard E. Lomax.
62 *Surgery of the Stomach, with Report of Cases. Albert Vander Veer.
63 *Therapeutic Effects of Roentgen Rays on Malignant Growth; Report of Cases. Arthur F. Holding.

61. **Infantile Diabetes Mellitus.**—Diabetes in children has not an extensive literature, but seems to be pretty thoroughly reviewed by Lomax, who describes the symptoms and reports cases. He discusses the general subject of diabetes, its pathology, etc., and remarks that no recoveries from infantile diabetes have been recorded. The cases reported varied from 2 to 16 years of age. One case in an adult was also mentioned. Some benefit seems to be derived with occasional fasts for twenty-four hours or so in removing unfavorable symptoms for the time being.

62. **Surgery of the Stomach.**—Vander Veer discusses surgery of the stomach, and reports two cases of complete removal of the organ, one of which was successful.

63. **Roentgen Rays.**—Holding reviews the cases published in the literature of malignant growths treated by this agency and reports personal observations of a number. He thinks that, from the uniformly good results reported, we may be too sanguine as regards the beneficial effects of the rays in malignant tumors. There are probably unsuccessful cases that are not reported.

Annals of Gynecology and Pediatry, Boston.

February.

64 *The Roentgen Ray in Gynecology. Eden V. Delphey.
65 Report of a Case with Autopsy. Loren A. Sanders.
66 *Further Report on the Use of Ethyl Bromid as a Primary Anesthesia to Ether. Emery Marvel.
67 *Portal Anastomosis, with Report of a Case. Daniel H. Craig.

64. **The Roentgen Ray in Gynecology.**—Delphey finds that the *x*-ray has a somewhat lesser value in the diagnosis in gynecologic conditions, and is principally useful in the treatment of malignant neoplasms.

66. **Ethyl Bromid Anesthesia.**—Marvel finds the advantages of using ethyl bromid anesthesia as a preliminary to ether anesthesia over that of the administration of ether alone, are the lesser time required, reduction of the discomfort to the patient taking ether by the absence of bronchial irritation and increased mucous secretions, less excitement and the danger of injury to which the first stage of ether narcosis is liable, the smaller quantity of ether required, more rapid regaining of consciousness and the lessened tendency to post-anesthetic vomiting. He has employed the method in 33 cases since the former report which he made, and 30 of these were celiotomies. The time required to secure unconsciousness varied from ten seconds to two minutes, an average of twenty-five seconds.

67. **Portal Anastomosis.**—The case reported by Craig seemed to be completely relieved by the Talma-Morrison operation, which is described. The technic was somewhat different from that ordinarily used. The lower extremity of the omentum after having been some time exposed to the air and rubbed with a dry gauze sponge, was tucked down into the sulcus formed by separating the peritoneum about two inches in all directions, being placed thus between the outer surface of the peritoneum and the muscle. Six catgut sutures were used to secure the end of the omentum within this pocket to the

abdominal parietes. The peritoneum was closed about and above the omentum with interrupted catgut and the sutures and abdomen closed in three layers. Multiple adhesions between various organs and parietes seemed unnecessary and by making an incision in the lower half of the abdomen, instead of the upper half, the physiologic function of the omentum of protecting the intestines was preserved and equally efficient adhesions secured.

86 Memoir of J. M. Da Costa, M.D. Mary A. Clarke.

77. **Diseases of the Pancreas.**—Deaver's article is a complete review of the various disorders of the pancreas up to the most recent acquisitions, describing the methods of treatment, operations, etc., and quoting extensively from the literature. In conclusion Wilbert gives some data as regards *x*-ray findings with the pancreas and it appears that it is possible to note decided changes in the organ.

79. **Cirrhoses of the Liver.**—The views ordinarily held in regard to hepatic cirrhoses are, according to Robinson, not always correct. The facts do not justify the gloomy prognoses that have been so generally given to these affections. There are different forms and degrees and not all are alike serious. He describes the different forms, atrophic, hypertrophic, and syphilitic. The former he claims are in reality of long duration as their earlier stages are not recognized. The imperative thing to do is to absolutely shut off alcohol. In the hypertrophic form he holds that the typical Hanot's cirrhosis must be rare. He does not recall a single typical case in his observation. Ascites is not the rule, but jaundice is, and in these respects it differs markedly from the atrophic type. The causation of this form of hepatic cirrhosis is obscure; the spleen often being enlarged, a malarial origin is sometimes suspected. Syphilitic cirrhosis resembles sometimes one and sometimes the other form. There may be ascites, jaundice or both together, or neither may occur. He holds that there is little doubt as to hypertrophic and atrophic alcoholic cirrhoses being distinct forms of disease and not different types of the same. In one the lesion is markedly multilobular, in the other it is monolobular in quite a pronounced degree. As Fagge has shown, cirrhosis often becomes quiescent before it reaches its final stage, and Flint seems to corroborate this view. The prognosis is far better in the hypertrophic and syphilitic than in the atrophic form. In conclusion, he speaks of surgery, Talma's operation more particularly, and reports a number of cases of this "omental anastomosis."

81. **Mixed Tumors of the Thyroid Gland.**—Loeb summarizes in substance as follows: Mixed tumors of the type of carcinosarcoma have been found in both man and animals. All have some characteristic point in common. Although carcinosarcomata occur elsewhere, the majority of them are found in the thyroid. They are also found in the thyroid in combinations of new-formed bone and sarcoma. The facts that have been cited in favor of the embryonic origin of mixed tumors can not be applied in the case of these. That a tumor is a mixed tumor is not in itself sufficient to prove its embryonic origin. It is not possible to determine with certainty, from the character of the constituent parts of a mixed tumor, from what kind of embryonic cells such a tumor is derived. Heterotopic tumor formations need not necessarily be produced by displaced blastomeres.

82. **Herpes Zoster and Pneumonia.**—Howard reports cases illustrating the relations of herpes zoster and pneumonia, and concludes that zoster is a pathologic condition like pneumonia, with definite lesions of certain sensory ganglia, sensory nerves and the skin, capable of being excited by a variety of causes. It is probable that the primary ganglionic lesions are commonly due directly or indirectly to the soluble toxins of various micro-organisms. The skin lesions may be on the head, neck, trunk or extremities, corresponding to the gasserian and posterior root ganglia affected. Various forms can be distinguished: 1. Spontaneous or primary herpes thought by Head, Carpenter and others, to be a specific infectious disease, the specific causal agent of which has a special affinity for certain sensory ganglia (posterior, spinal and gasserian). 2. Herpes occurring after certain definite toxic agents, as arsenic and carbonic oxid gas, etc. 3. Herpes in the course of certain infectious diseases like pneumonia, cerebrospinal meningitis and probably malaria and typhoid. In all three of these forms, the ganglia and the skin lesions are the same and the processes presumably identical. 4. Herpes simplex so-called, affecting the lips and nose in coryza, gastrointestinal intoxication, etc., and genitals (herpes genitalis) has not been sufficiently investigated to be classified; no evidence for or against its connection with changes in the nervous system exists. As far as skin changes in herpes are concerned, they are illustrations of particular forms of necrosis and inflammatory reaction, and, as in similar lesions in other organs, can probably be excited in a variety of ways. 4. Herpes should be classified according to its relation to changes in the nervous system, and every opportunity embraced to extend our knowledge in this direction.

83. **Lithium.**—From clinical data and a series of experiments on cats and dogs, Good offers the following conclusions:

1. Lithium is excreted in the saliva, into the stomach and bowel, and in the urine. The greater amount is excreted in the urine, though more appears in the stomach and bowel when nausea, vomiting, and diarrhea have been profuse. It can usually be demonstrated in the secretions within ten minutes after a hypodermic injection, though its excretion proceeds slowly, for I have found it in the secretions twenty-three days after the injections were stopped. 2. Lithium salts given to animals, hypodermically or by the stomach, cause, sooner or later, fatal gastro-enteritis. This gastro-enteritis, is, undoubtedly, connected with the excretion of the metal through the bowel wall. 3. Lithium salts do not possess any diuretic action that can not be accounted for by their salt action. They render the urine alkaline, and thus act like other alkalies. 4. Lithium carbonate, in fifteen to twenty-grain doses, and lithia tablets have been known to cause gastro-intestinal symptoms in man. 5. Dilute solutions of lithium salts are not solvents for uric acid or urates.

84. **Ureteritis in the Female.**—Garceau's article is a complete study of ureteral disease as it appears in the female. He classifies it as simple ureteritis of the acute or chronic form, ureteritis with obstruction and tubercular ureteritis. In

the former he notices particularly one sign of great diagnostic importance, that is, an excess of desquamated epithelium which may or may not be associated with the presence of pus on the affected side. He thinks the gonococcus the germ to be chiefly dreaded, and points out the diagnostic and clinical symptoms. There is one affection which may be confounded with it, that is ureteral stricture; but as stricture is a sequel of the disease, and as ureteritis always accompanies stricture, the distinction is not marked. If a stricture is suspected passing a graduated bougie will clear up the diagnosis. Most frequently simple ureteritis is not recognized at all or is treated as a chronic cystitis or as a reflex bladder trouble. Cystoscopic examination is always advisable. The prognosis is bad if it has existed a long time. As to treatment, he recommends a non-stimulating diet, attention to the secretion of the skin, moderate exercise, regularity of living, use of drugs to modify the acidity of the urine and sometimes as disinfectants and topical applications to the bladder, a solution of 5 to 10 per cent. nitrate of silver. He illustrates the apparatus he has himself devised for topical applications to the ureter itself, consisting of a fine silver tube with a blunt-pointed extremity and a bulbous expansion a short distance from its end. This is introduced into the ureteral orifice as far as the bulb permits, and the bulbous expansion held here in close contact to prevent regurgitation of liquid. Then the silver is injected. He has only used this a few times and it is too early to say what the results will be of this method of treatment. Ureteritis with obstruction is discussed at length. It is a long-standing affection and very difficult to cure. The danger is on the part of the nervous system, which is constantly irritated, the mental equilibrium being often more or less disturbed. A constant nagging desire to urinate is felt. Treatment generally has for its object the restoration of the caliber of the lumen. He speaks with some reserve as regards dilatation methods. They are extremely painful and the patient does not always submit. The best operation is one which exposes the ureter through the extraperitoneal incision, after preliminary introduction of a ureteral catheter. The stricture may then be cut on the catheter and the two angles of the incision united by means of fine suture. The sewing should not be done until the rest of the canal has been explored for high strictures. If the stricture is of great length and near the bladder, it is advisable to transplant the ureter. Any stricture below the pelvic brim can be treated in this way. If there is a high stricture the only other resource is a nephrectomy or the establishment of an artificial loin fistula. The condition of the opposite kidney should always be considered. Calculous obstruction is noticed and cases reported. The prognosis in ureteral obstruction depends on the length of time it has lasted and whether infection of the upper urinary passages has taken place. Tubercular ureteritis receives but comparatively brief mention at the end of the article. He gives a tabulated statement of the cases and the results of operations including those in which the ureter has been abandoned, and it appears that complete recovery can take place even if this is the case. If the ureter is abandoned, however, further complications may be expected. The most to be dreaded is tuberculosis in some other part of the body. He thinks nephro-ureterectomy will be more commonly done in the future than in the past, and total nephro-ureterectomy should be done in all cases where the condition warrants it.

1. **Cancer of the Tongue.**—In a former article Butlin has given his results, which show that success in the operative treatment of cancer of the tongue is much greater than had been supposed. He has in his present paper brought together all the results of his experience. Out of 129 cases, 32 may be regarded as absolute successes. If we take away all the cases that died of other diseases after the operation, the total is then 32 to 117 cases, or nearly 27 per cent. If he had exercised greater care in the selection of cases the percentage might have been still higher, but the rule has been to operate whenever there has been the smallest chance of relieving the patient; still he thinks he could reduce his mortality considerably in a future series of equal numbers. He reviews the predisposing causes of cancer, particularly the cracks, fissures, ulcers and other lesions of the tongue which form the basis for cancerous growths. Carcinoma may begin in almost any form, a little warty growth, patch of leukoplakia, etc. He says he has asked himself over and over again why physicians watch these dangerous conditions for weeks and months until cancer is fairly established without action. He accounts for it by the lack of knowledge of the actual pre-cancerous condition and the prejudice against operations on the tongue on the part of the patients—the fear that it will destroy the power of speech. The last is needless, as he has shown, for with any considerable portion of tongue being left, the ability to speak is retained. He says in the first place if we are consulted about warts or warty growths, particularly of the tongue, no time should be lost in removing them. In the case of indolent ulcers, caused by the decay of teeth or any such cause, the cause of irritation should be removed at once, and if the ulcer does not then heal, cut it out. He has often advised in cases of superficial glossitis where the tongue was constantly irritated, to have that part removed even when there is no sign of any pre-cancerous condition. He gives that advice, particularly when the under surface of the tongue is healthy, so that it can be used as a flap.

2. **Study of Cancer Mortality.**—Statistics of the town of Dundee are analyzed by Templeman and he finds as a summary the following:

1. That the death-rate from cancer as a whole during the twenty-five years under review has more than doubled, having increased from 7.27 to 16.92 per 10,000 of the population over the age of 20. 2. That this increase is greatest at ages over 45, is common to both sexes, but more marked in the male sex, though the actual mortality is higher among females. 3. That in females this is chiefly due to an increase in malignant affections of the abdominal viscera. 4. That uterine cancer and cancer of the breast in females have increased, though not in any marked degree. 5. That cancer of the rectum also shows a slight increase in both sexes. 6. That in males the highest mortality is from cancer of the abdominal viscera. 7. That in males cancer of the mouth and upper digestive tract has also greatly increased. 8. That, therefore, cancer of regions which may be described as "accessible" has increased, as well as that of parts which are not accessible, and where the diagnosis is more difficult, but the increase in the latter is out of all proportion to that in the former class. 9. That during the same period there has been a great improvement both in clinical and pathological diagnosis, as well as in death certification, and consequently a considerable diminution in returns from such indefinite conditions as "old age" and "disease" of the various organs (without any specification of its nature). 10. That this must to a considerable extent have helped to swell the returns of death from "cancer."

He does not think the facts here stated absolutely account for the great increase in cancer mortality, which is the fact, and a substantial one, though not so alarming as the general public believe or some recent statements have intimated. It is difficult to assign any special cause to the increase. Before we can solve the problem of increased cancer, we must have some more accurate knowledge of its etiology, and if parasitic in its nature, we must know something of the life history of the organism that caused it.

9. **Uterine Fibroids.**—The question as to the retention of certain parts of the ovary in case of hysterectomy is mentioned first in this lecture by Doran. While this conservative plan has its merits, he thinks they have been overestimated. He analyzes his own cases and finds that there are certain questions to be answered in regard to it: 1. Whether the period always ceases after hysterectomy with removal of both ovaries; 2, if their removal really involves bad menopause symptoms; 3, if when more or less is left of the ovaries, the period will continue regularly, and lastly, if this preservation of the ovaries be wholly beneficial. In his 25 cases where both ovaries were removed the period ceased, with only four exceptions; in one it appeared once in six months; in one it appeared irregularly thirteen months after operation; in one it was kept up for two years, and in the fourth for two years and seven months. The second question is closely associated with the first, does removal of the ovaries necessarily cause these bad symptoms? In 21 cases, those where the menopause was complete after removal of both ovaries, there were no symptoms whatever in seven, mild and infrequent flushing in seven, and severe symptoms in seven. In six of the last seven there were simply the usual subjective evidences of change of life, severe enough to give discomfort. The seventh developed symptoms of persecutory mania a few months after the operation, but this was merely a repetition of a former attack, and

he does not attribute too much value to it. We must not be too ready to put the blame on the operation. Marked corpulence developing rapidly was noted in two cases, one of 30 and one of 50 years. He thinks from the results that it is best to leave one or both ovaries if healthy, the more so since it involves a smaller wound, but he does not consider retention of the ovaries a matter of supreme importance and does not guarantee the patient against a severe menopause. The question whether the period remains regular after hysterectomy when more or less is left of the ovaries, was answered in his experience by the fact that in nearly 53 per cent. the period did not appear after operation and in 5 of the 9 the menopause was distinctly severe. The question as to the retention of a portion of the uterus above the cervix, which is insisted on by Abel and Zweifel, though rejected by Kelly, is mentioned and Doran's own experience to a certain extent supports the Abel-Zweifel theory. As to the question whether leaving the ovaries or sparing one ovary is harmful or not, he points out that inflammation may occur, but the most serious matter is their possibility of its becoming the seat of tumor. The question as to previous hemorrhage has to be taken into account also, but he can not draw any conclusion. According to Doran's experience the family history of fibroids is more interesting than important. It sometimes is detected, but is not a sound guide to the prognosis and treatment. The questions of the diagnostic importance of hemorrhage and the occurrence of ascites are also discussed and the author thinks that the latter subject at least deserves more attention than it has received. He is inclined to doubt the occurrence of absorption of fibroids, though there is no doubt that they sometimes vanish. The process which brings about this result, he holds, is probably necrosis or aseptic necrobiosis not rare in fibroid tumors; the source of nutrition fails and the fibroid softens and disintegrates. This necrosis of fibroids is a matter of great clinical interest, especially if septic. It usually produces a certain amount of disturbance of health and may lead to trouble. While the condition may justify hysterectomy it is not always advisable to urge the removal of a small fibroid on the plea that it may become necrotic. Impaction of fibroids in the pelvis, the "cup and ball" fibroid is also mentioned and the relation between fibroid uterus and disease of the appendages. It does not always follow that the imbedding of the ovaries in soft peritoneal adhesion with congested tube require their sacrifice. Necrotic fibroids do not necessarily affect the appendages, whether they are originally septic or not. The infection is more often derived, he thinks, from the contents of the uterine cavity.

10. **Paralyses of Children.**—Jones criticises the neglect of orthopedic surgery on the part of physicians; there is a tendency to turn their patients over to the instrument makers, and this has been too much the practice in England. He insists on the importance of working on the muscles, stretching and lengthening the flexors in acute infantile paralysis and putting the extensors in such a position that their structural shortening will ensue. We must not confuse muscles which for years have been useless with muscles that are positively paralyzed. The operations of tendon transplantation and arthrodesis are also noted in relation to spinal paralysis. The nearest efficient tendon should be employed if sufficiently strong rather than one from a distance and the selection should be made, if possible, of a re-enforcing muscle the mass of which is parallel to the re-enforced. If the tendon is to be spliced by tendon, it should be done as near its insertion as practicable, to avoid as much as possible a yielding of the paralyzed section, which is apt to occur. If possible to transplant into the periosteum he has found that the best way. The proximal part of the re-enforcing tendon should be fixed into the paralyzed tendon so that it can be maintained as tense as possible, if we are to have it do its work. He describes the operation of arthrodesis, and speaks of its advantages, in flail-like joints. Cerebral paralysis of the spastic type is also discussed at length by Jones, who puts the idiot, the microcephalic, and the violent irritable type of diplegic outside of the class which can be successfully treated. The treatment of any condition short of this may be undertaken with varying success, allowing that it may require a long period. The treatment of the hand and arm in infantile hemiplegia is less promising than the diplegic cases. If the spasm is never relaxed treatment is futile. He speaks particularly of the importance of flexing the elbow superficially, hyper-extending the wrist as the dominant deformities are pronation and carpal flexion. It may be taken as a rule that the fixation of the spastic muscles in a position opposed to their contraction lessens the severity of their spasm. This is perhaps the best explanation of how the good results occur. In the later period of treatment tenotomy or tendon transplantation may be required and no opportunity should be lost in proper cases of performing tenotomy. The treatment of spastic paralysis involves operative, mechanical and educational stages. If the surgeon is not satisfied after the case has been under his care for twelve months, he would do best to leave it alone.

29 Some Recent Work on the Etiology and Treatment of Eclampsia. W. E. Fothergill.
30 A Review of Recent Work on Ophthalmology. E. Treacher Collins.
31 The Health Aspects of London Locomotion. Louis C. Parkes.

20. **Tuberculosis.**—Allbutt depreciates the panicky fears on the part of the public and anything encouraging them, and advocates sanatorium treatment, establishment of proper vital resistance, and the precautions against the dissemination of the microbe by care of the sputum, etc.

21. **Urinary Chemistry.**—Smith reports a case in which a bulky sediment of leucin was found in the urine. He remarks that he does not know of any previously-recorded cases in which it appeared in such quantities not associated with tyrosin. The patient had simply apparent digestive disorders and a frequent desire to urinate. The second part of his article is on the reaction between urea and formaldehyd and its clinical significance. The reaction consisted in a white deposit consisting of discoid, very small oblong and oval bodies, single, or arranged in pairs, somewhaat resembling large bacteria. The chemical study of the substances lead him to formulate the following three points of practical interest as regards relation of formalin to the urine:

1. It yields with urea a white precipitate (probably methyleneurea) which might easily be mistaken for leucin. 2. If present in urine formaldehyd will reduce the copper test, and so introduces a fallacy in testing for sugar. 3. Formaldehyd interferes with the detection of small amounts of albumin by means of heat and acetic acid.

23. **Relaxed Sphincter Ani.**—The following is a description of Robson's operation which was performed for incontinence and paralyzed sphincter ani following ablation of the pils-bearing area:

With the patient in the lithotomy position, a semilunar incision was made at the junction of skin and mucous membrane around the anterior half of the anus, and this was deepened about ¼ to ½ inch. The upper and lower margins were then separated by being drawn apart by means of forceps, so as to make the semilunar slit into a lozenge-shaped cavity, and this cavity was then closed by bringing together the sides by buried catgut sutures and the skin by silkworm-gut sutures. It will be seen that the wound is entirely external to the bowel and that it diminishes the size of the anus; but it does more than merely contract the orifice, for it restores the power of the sphincter muscles.

The description is more intelligible with the schematic illustrations which he gives. The operation probably acts in one or both of two ways: 1. By shortening of the sphincter muscle, enabling it to grip the anal orifice or by bringing together the torn ends of the muscle. Whatever may be the explanation, the operation answers the purpose for which it was designed, and the patient was completely relieved of the incontinence.

24. **Trigger-Finger.**—Four cases are described by Barnard, who discusses the condition and its probable cause. The thumb seems to be most commonly affected, next the ring, the middle, the little and the index finger. The most typical cases are undoubtedly due to changes in the tendon, producing a local enlargement which snaps below the osseofibrous arch opposite the metacarpo-phalangeal joint, or, in the case of the thumb, between the two sesamoid bones and beneath the ligament which unites them. The cause of the snap, however, may be in the joint and some irregularity of the anterior surface producing the trigger action. For the treatment of those due to sudden injuries, rest on a splint with pressure from a pad placed over the swelling and later massage, appears to be the suitable and successful treatment. Where a definite nodule has been formed and persists, it is correct to expose the tendon and dilate according to what is found, either removing the mechanical obstacle or overcoming the disproportion between the tendon and its sheath. The most scrupulous asepsis must be followed.

25. **Acute Rheumatism.**—The substance of this article is largely included in that already abstracted in THE JOURNAL of February 28, ¶1, p. 609, by R. M. Beatson and E. W. Ainley Walker.

26. **Paraffin Prothesis.**—This gives in substance Paget's experience, which has been already analyzed in a former article, abstracted in THE JOURNAL of January 31, ¶4, p. 338.

27. **Color Blindness.**—Bickerton takes up this question, showing the deficiencies of present practice, the imperfections of the Holmgren test, the frequent successful appeals, which destroy confidence in the test and the necessity of examining for color sense not only the officers, but the sailors who may be put in positions of trust as lookouts, etc., where the perfection of the color perception is essential.

36 On Nagana and Other Trypanosomes. Dr. Schilling.

33. **Kala-Azar.**—Bassett-Smith points out the differences which exist between kala-azar and Malta fever, which have been considered by Bentley to be identical. He thinks the principal differences of kala-azar from Malta fever are in the greater degree of infectivity and more rapid diffusion, the high mortality, more constant hypertrophy of the liver and spleen and the greater degree of emaciation and pigmentation produced on the one hand and the absence of those neuralgias and peripheral neuritic symptoms of Malta fever on the other. The identity of the two diseases is not proven.

37 *Report of Committee on Liqueurs and Essences Used in Their Manufacture.
38 Note sur l'urgente nécessité d'appliquer la vaccine obligatoire à l' Indo-Chine française. Hervieux.

37. **Liqueurs and Essences.**—Laborde is chairman of a committee which comprises Brouardel, Lancereaux, Cornil, Magnan, Pouchet, Motet and Joffroy. Their report gives a list of the most dangerous essences used in the production of liqueurs, and urges their absolute prohibition or stringent measures for their control. The essence or volatile oil of absinthe is so dangerous that its sale should be absolutely prohibited, as also the oil of rue, of gaultheria, of hyssop, of illicium, of angustura, salicylic aldehyd and benzoic aldehyd or prussic acid. All these essences—the French use the term essence to express a volatile oil—are used in the manufacture of various liqueurs, and they should be unconditionally prohibited, on account of their peculiarly toxic character, or at least a prohibitory tax imposed. In a second list they include the essences, whose sale should be regulated, but need not be suppressed entirely. This includes the oil of peppermint, spirit of anise, oil of nutmeg, oil of cloves, oil of mace and sixteen others. The report concludes with a clinical portrayal of some of the effects of the habitual use of beverages concocted with these volatile oils, followed into succeeding generations, referring to Féré's research on the influence of alcohol and essences on the incubation of hen's eggs. The secret recipes for several liqueurs are given, showing the large proportion and the number of dangerous essences that enter into their composition.

81 Une nouvelle observation de phlébite syphilitique secondaire. A. Renault and G. Roussy.

47. **Mumps and the Pneumococcus.**—Simonin describes 8 cases in which a pneumococcus infection coincided with or preceded the mumps. Laryngo-bronchitis has been frequently observed in the course of or consecutive to mumps, and his experience indicates that this disease induces a peculiar predisposition to pneumococcus infection, and also that the latter

germ acquires greater virulence in its symbiosis with the mumps germ. He therefore urges prophylactic measures to avoid the double infection.

54. **Elimination in Chronic Sclerous Nephritis.**—Claude and Burth made a most careful study of seven cases of this affection and tabulate the findings. They show that the elimination in the urine is profuse for a long time, thanks to a peculiar adaptation of the cardio-vascular system to the condition of the kidney. The glomerulo-tubular systems become hypertrophied and compensate the lesions of sclerosis until the heart becomes affected or some infection or intoxication causes inflammation in the globerulo-tubular systems, after which insufficiency of the kidney becomes manifest and more or less permanent.

58-59. **Typhoid Bacillus in the Blood.**—Courmont found the typhoid bacillus constantly in the blood in 37 typhoid patients, all adults, from the first days of the disease to the end of the third week. They inoculated 300 to 500 c.c. of bouillon with 2 to 4 c.c. of blood. In 6 cases the bacilli were found long before the agglutinating test was positive. Widal's experience has been that he could not cultivate the bacillus from the blood in 5 very mild cases of typhoid fever. It was found in 17 out of 20 moderate or severe cases, examined from the fifth to the fifteenth day. In 5 cases the staphylococcus was found with the typhoid bacillus, and in 2 of the negative cases it was found alone. In another negative case a streptococcus and a colon bacillus were found in the blood. He inoculates 400 c.c. of bouillon with 4 c.c. of blood. Agglutination was positive in all the cases.

61. **Injections of Air in Treatment of Neuralgias.**—Marie has been giving Cordier's method of treating neuralgia by injections of air a trial in his service. He reports that 2 out of 3 patients with sciatica were benefited after several repetitions of the injection. One of the patients was relieved at once and permanently. A third of a liter of air was injected at three different points. A patient with neuralgic zona was also relieved at once and likewise a tabetic. In lumbago the relief was merely transient.

62 *et seq.* **Colloid Silver in Infectious Diseases.**—Netter is professor agrégé and physician to the Trousseau Hospital, where he has been testing since November 15, Credé's colloid silver, better known as collargol. A child of 7 with acute pericarditis received an intravenous injection of 2 c.c. of a 1 per cent. solution, with three frictions of 2 gm. each of the collargol salve. The child's recovery was rapid, resembling in every respect the curves of pericarditis published by Wenckebach, showing the great benefits of collargol treatment. Other cases were pneumonia, meningitis and typhoid fever and the results were apparently good. Netter remarks that the favorable action of the collargol is first marked by the subsidence of the temperature, then by the general well-being, similar to the relief afforded by antidiphtheria serum. Renon states that Follet of Paris has been treating patients with various affections since 1898, with silver powder in suspension. He reports that a large number with acute or chronic tuberculosis have been treated with silver powder injected once or twice a week. He mixes about 1 gm. of the powder with 60 gm. of artificial serum and 10 gm. of oil of guaiacol and eucalyptol. The cough and expectoration have gradually disappeared and the majority now consider themselves cured. The injections are made in the buttocks and are not painful. Renon also calls attention to a patient with typhoid fever treated after the tenth day with collargol frictions, using 3 gm. at a time of the 15 per cent. salve. The temperature fell after the second rub and the disease was evidently aborted after the fourth. No other treatment was used and the depression and delirium of the onset indicated that the case promised to be severe. Martin found rapid improvement in 2 cases of pneumonia. Netter's experience now includes 9 cases of pneumonia, and the same of typhoid fever, 14 of bronchopneumonia, 4 of severe scarlet fever and 37 of diphtheria. He emphasizes especially the remarkable results attained with it in several cases of malignant diphtheria. The results have also been fine in a case of puerperal infection and in one of infectious endocarditis and of endocarditis in articular rheumatism. No benefit has been apparent to date in tubercular affections in his experience, nor in any cases of cerebrospinal meningitis, erysipelas, phlegmon of the breast or adenitis. He ascribes the efficacy of the colloid silver to its catalytic action rather than to its bactericidal power. Bredig has established that platinum, gold and silver in the colloid state behave like a true ferment, an inorganic ferment accelerating the chemical transformations by their presence in infinitesimal quantities the same as the figured and the organic ferments.

78. **Organ Treatment of Cirrhosis of Liver.**—A woman had been treated at intervals for nearly a year on account of advanced cirrhosis of the liver. She was much emaciated and scarcely urinated at all, while the ascites and edema were excessive and recurred after every puncture, notwithstanding a strict milk diet and diuretics. Pig's liver was then ordered for her and she took 150 gm. a day. In a few days the urine became clear and abundant. The edema and ascites subsided and the patient was able to get up in ten days. The improvement continued and in five months she was able to abandon the liver without recurrence of symptoms. About a year after the last symptoms had disappeared she returned to the hospital complaining of scanty urine (800 gm. a day). It contained urobilin. After resumption of the liver for a few days, the urine returned to normal and the patient's recovery has been undisturbed since, more than two years and a half since the liver treatment was first commenced. Galliard has treated a number of cases of cirrhosis in this way during the past few years, but none showed such surprising benefit as this one.

79. **Local Treatment of Gumma.**—The gumma developed on the leg at the same time as a keratitis was observed, both indications of hereditary syphilis, presenting no manifestations until the subject was 25. The gumma was as large as a hen's egg, and was treated with daily local injections of 2 c.c. of a 3 per cent. solution of potassium iodid at a little distance from the lesion. By the seventh day it had entirely disappeared.

94 Eeine neue wirksame (effective) Lampe für licht-therapeutische Zwecke (for phototherapy). H. Strebel (Munich).

89. **Differentiation of Human and Animal Bones by the Biologic Test.**—Schütze has found it possible to differentiate scraps of bone in forensic cases by the biologic test when all other measures had failed. It is indispensable, however, that enough albuminoid substance should still cling to the bone to induce the specific cloudiness. It is very seldom that a scrap of bone sent for examination is entirely free from some albuminoid matter.

90. **The Physiologic Salt Solution.**—Engelmann insists that the term physiologic salt solution should be exclusively reserved for the true isotonic solution, which is 9 per cent. Otherwise the term should be dropped, or used merely in a relative sense, always adding the percentage of concentration.

91. **Structure and Etiology of Cancer.**—Feinberg has been applying the methylene-blue-eosin stain to the study of the cells found in cancer, and states that it reveals a number of cells in which the nucleus is of the peculiar and exclusive type of independent unicellular living beings. It differs from the nucleus of all other cells in that it never contains nucleoles or anything suggesting a framework for the nucleus. The chromatin substance, which in other cells forms the framework, in these cells is collected in a single compact body, which he calls the "nucleus point" (Kernpunkt). This "nucleus point" is always to be found when the cell is at rest. The constant discovery in cancer tissue of numbers of these cells with the structure of independent unicellular organisms is, he thinks, an important factor in the etiology of malignant neoplasms. Of all the writers who have published communications in regard to the discovery of assumed parasites, he remarks that those of Soudakewicz, Foa, Plimmer and Sawtschenko are the only ones based on the technic of an expert. Closer study will probably show that the same object was seen by each of these observers, and that it is identical with the unicellular living animal or vegetable organism he describes.

92. **Bandage for Fractured Phalanx.**—Clamann bends the finger over a covered spool or roll of linen, and fastens it firmly in this position by a long strip of adhesive plaster passing from the back of the hand the whole length of the finger and then brought up on the back of the hand again. In order to make the plaster fit better, the ends are slit at the nail and also on the back of the hand, and slits are cut at the points of the knuckles.

95. **The Kidney in Scarlet Fever and Diphtheria.**—Huebner describes his examination of the kidney in two pure cases of each disease. He found that the organ was the seat of a pronounced hemorrhagic affection in scarlet fever. The glomeruli were principally involved and the epithelium secondarily. The vascular portion of the kidney was thus predominantly and primarily affected. The aspect was different in diphtheria; here there was little if any hemorrhagic tendency. The degeneration of the epithelium was primary. It occurred only in parts.

96. **Serum Treatment of Exophthalmic Goiter.**—Lanz commenced in 1894 to apply the milk of goats, after ablation of the thyroid gland, to the treatment of Basedow's disease. He has now an experience of 6 cases, in which the patients were supplied with a thyroidectomized goat, and of 3 other cases in which the symptoms were less pronounced or other remedies were used as adjuvants. He describes the particulars of the series of 6 cases and the results attained will evidently attract attention. His Case 3 was a woman of 38, apparently in the last stage of Basedow's disease. She had to be carried into the train, was confused, stuttered, wept and sobbed instead of replying to questions, with extreme tremor of the four extremities, emaciated, skin moist over entire body, tachycardia of 140 to 160, edema of legs, extreme exophthalmus, struma very large, neck 39 cm. in circumference, apex beat abnormally strong, long suppression of menses and the typical heart symptoms of the disease. She was put on the milk of a goat thyroidectomized for the purpose and improved rapidly. In five or six weeks the heart symptoms began to subside; the menses returned later, and by the end of the year she announced herself as completely restored. A letter from her attending physician is quoted at length. He states that the tremor, excitability and other nervous symptoms have entirely subsided. The pulse has fallen from 120 or 140 to 80. The excessive thirst has disappeared and the weight has increased from 98 to 126 pounds. There is no longer any insomnia; the eyeballs have retrogressed, and the patient feels perfectly well. The struma has not diminished in size and the circumference of the neck is about the same as before. The symptoms did not recur after suspension of the milk at the end of the year. The goat which supplied the patient in Case 4 gave about one liter of milk. After five months the supply of milk failed, but the improvement obtained during the milk treatment did not subside on suspension. Her attending physician writes that the patient's weight has increased from 78 to 110 pounds, with pulse 80 when quiet. The prominence of the eyeballs is no longer noticeable. All previous treatment had been ineffectual. Case 7 was a man of 25, with a negative family history. Six weeks after he had been supplied with a thyroidectomized goat his physician writes that the improvement gained has been permanent. Lanz calls attention to the fact that it is easy to mistake the salivary glands for the thyroid in the goat, and also to overlook the isthmus glandulæ thyreoidæ. Other attempts at serum treatment of Basedow's disease have been made with thyroidectomized dogs. Schultes has recently reported great benefit derived from the serum of thyroidectomized sheep, Möbius' "Antithyreoidin." The patient's mind was affected and, consequently, the benefits derived could not be attributed to suggestion. His case is also interesting from the fact that the symptoms recurred on suspension of the treatment and promptly subsided again on its resumption.

97. **Antithyreoidin.**—This is the name applied to the serum of thyroidectomized sheep. Möbius has been using it in doses of 5 gm. every second day and the results have established its harmlessness and the unmistakable benefit derived. His patients had all suffered for years from benign Basedow's disease, and all were unmistakably improved. The only objection to the remedy is the high price. He longs for some millionaire patients who could afford to try a course of the serum in much larger doses, as he anticipates better results from more vigorous treatment.

99. **Therapeutic Application of the Action of Ions.**—Pauli believes that he has succeeded in establishing several laws in regard to the manifold analogies between the alterations in the condition of colloid substances with the processes that occur in living matter. He gives his reasons for assuming that the precipitating action of a salt on the albuminoid bodies is principally the result of the algebraic sum of the actions of the single ions. Also that the anions and the cations have an antagonistic action, the latter causing precipitation and the former inhibiting it. The salts can thus be grouped by their precipitating power, as he shows in a table, the fluorids of magnesium, potassium, sodium and lithium being the strongest precipitators and the bromids, iodids and rhodanids the weakest. The precipitating power increases with the

cations from magnesium to lithium, and decreases with the anions from the fluorids to the rhodanids. The fact that the rhodanids are the last link in this regular chain suggests that they may likewise possess therapeutic value like the iodids just above them. Pauli has been testing them in this respect on 35 patients with various affections, administering 1 gm. of sodium rhodanid as the maximum dose. In 10 cases of neuroses or organic nervous affections the symptoms rapidly subsided, and recurred on suspension of the drug, while they disappeared again on its resumption. The only exception was a case with pains in the epigastrium, the pathogeny of which is still obscure. In 11 cases of arteriosclerosis, the pains and oppression subsided, the exacerbations became less and less intense and the vertigo and sounds in the head completely vanished. In every case the blood pressure sank from 10 to 25 per cent. On suspension of the drug, the blood pressure rose again in three or four days to its original figure, and some of the symptoms recurred, but subsided again on its resumption. The efficacy of the rhodan compounds in such small doses is explained by their low molecular value; 1 gm. of sodium rhodanid is equivalent to 2.15 gm. of the bromid and 2.82 of the iodid. Besides the sedative and blood pressure reducing action of the rhodanid there is probably another factor in its therapeutic effect, its power to induce the formation of easily soluble combinations of protein which favor the elimination of the heavy metals to an extreme degree and is particularly useful in case of chronic lead or other poisoning. It also has a marked effect in favoring the elimination of calcium, as he shows by research on the calcium ions. In 4 cases of kidney disease the sacral pains, neuralgias and insomnia vanished as the patients took the sulfocyanid in connection with a strict milk diet, showing that, to say the least, chronic albuminuria is no contraindication to it. The effect was strikingly beneficial also in 4 cases of syphilitic headache. As a further evidence of the close analogy between the rhodanids and the iodids is the fact that the former are liable also to induce acne and coryza, as occurred, to a slight extent, in a very few instances, but subsided on suspension of the drug. The rhodanid (sulfocyanid) has no apparent influence on the thyroid gland, even after months of use. It did not cause the slightest gastric disturbances in any case. The researches of Meyers and Overtons have established the relations between the "lipoid" elements of the cell and the non-ionized narcotics, and it is probable that the ionized combinations assail the albuminoid complexes of the protoplasm. As the normal cell ions are affected or displaced, the colloid conditions become altered and with them the functional activity.

106. **Operative Treatment of Lung.**—Treupel describes another case in which notable benefit was derived from an operation in a case of gangrenous abscess of the lung in a boy of 4. An exploratory puncture revealed only a serous, sterile fluid at first, although all signs pointed to an abscess, but ten days later the symptoms indicated a pyopneumothorax and puncture this time disclosed a fetid, gaseous, purulent exudate. The abscess had evidently perforated into the pleura, and he regrets that he had not operated earlier, before this perforation occurred. The serous effusion first found was undoubtedly the reaction of the pleura to the abscess in the vicinity, and should have been the signal for intervention, even if the lesion were known to be of tubercular origin, which was not established in this case.

108. **New Outlook in the Domain of Nutrition.**—Ascoli states that it is possible to detect particles of the food in the lymph by the biologic test after feeding dogs with raw eggs or roast fowl. The entrance of these precipitable particles into the circulation induces variations in the precipitins contained in the blood, and alters the balance of the pre-existing side-chain complexes. He found the same phenomenon in man after ingestion of roast beef, and thinks that it is the key to the pathogenesis of the so-called nutritional diatheses or affections.

110. **Thrombophlebitis in Measles.**—A healthy child, about the seventh day of the exanthem of measles, developed cerebral symptoms, with death four days later. The sinus longitudinalis was the seat of a necrotic thrombophlebitis, with extensive destruction of the surrounding parts. The kidney was also disseminated with infarcts. The case suggests that the measles process alone, without outside aid, affords a favorable soil for necrobiosis. Cnopf reviews a number of cases in the literature, in which a septic process coincided with measles, to sustain this view.

114. **Screw Gag.**—The two flat plates that form the gag are parallel and are introduced between the teeth close together. They are then separated by a screw in the handle, on the principle of a monkey wrench.

116. **Oxygen in Therapeutics.**—Kraus remarks that he has experimented on himself with inhalation of oxygen, and never noticed any special subjective or objective phenomena after inhaling it for more than an hour at a time. The pulse was unaffected, but the respiration was a little deeper. He experimented with it both at rest and during physical exercise, but could not detect any variance from ordinary conditions either in himself or in a number of anemic and diabetic subjects. On account of the negative results, he has never published an account of these quite extensive researches. The freezing-point of the blood was not altered in healthy persons, even after prolonged inhalation of oxygen. The proportion of chlorin remained approximately the same. In one patient with croupous pneumonia and extreme cyanosis, the chlorin was in the proportion of .635 per cent. before and .63 per cent. after prolonged inhalation of oxygen. The pulse and diuresis were not affected, but the patient stated that she felt "relieved." The process of oxidation in the organism is probably complex and requires oxidases as well as the oxygen itself. Inhalation of it does not relieve the death agony. Kraus has seen scarcely any but bad results follow its use in pneumonia, and it is generally useless in tuberculosis. In cardiac insufficiency and dilatation, it usually affords subjective relief, but the cyanosis never actually vanished in his experience. In the coma of morphin intoxication much better results were obtained from tracheotomy and artificial respiration for twenty to thirty-six hours. Oxygen never induced the slightest appreciable benefit in anemia nor in leukemia, diabetes and other constitutional diseases. The principal indication for its use is stenosis of the air passages. When only

a small quantity of air can reach the alveoles, it is rational to supply the air in as concentrated a form as possible. Oxygen is also useful in carbon oxid intoxication. In urgent cases intravenous injection may be preferable to inhalation.

117. **Infusion in Therapeutics.**—Ercklentz found that animals treated by infusion after otherwise fatal intoxication survived, and their organs showed little trace of the intoxication to which the control animals all succumbed with severe alterations in their organs. The best results, strange to say, were obtained, not from the true isotonic 9 per cent. salt solution, but with the 6 per cent. The benefit was most apparent the nearer the infusion approached to being continuous. In some of the tests the poison used entered so rapidly and firmly into combination with the nerve cells that the infusion was too late to affect it. The diuresis invariably induced did not eliminate any of the poison in these cases. The results of infusion after experimental injections of anilines and potassium chlorate harmonize with what is observed in the clinic, especially in respect to severe anemia, which is now regarded as a toxic affection, in septic affections and in uremia. Septic conditions are benefited to a remarkable extent by infusion. In a case of malignant endocarditis, for example, with extremely painful joint metastases, the swelling and pains in the joints vanished as if by magic after the infusion. A patient with puerperal sepsis was roused from her stupor, and another was undoubtedly saved by the systematic continuous use of infusion. Its efficacy in uremia is well known. Improvement and sometimes recovery followed the copious diuresis induced, but the specific gravity of the urine frequently remained high, and even rose higher with the increasing amount of urine. The results were always highly satisfactory in severe anemia. In one case the hemoglobin rose from 20 to 85 per cent. and the reds from 368,000 to 4,800,000. The morphologic alterations in the blood retrogressed, and the slight temperature subsided. So long as severe symptoms persist, one or two liters should be injected subcutaneously once to several times a day. When exceptionally prompt action is desired the intravenous route may be preferable, preceded, perhaps, by venesection. He concludes by advising the use exclusively of the .9 or .92 per cent. solution as the only isotonic one.

118. **Chinaphenin.**—This combination of quinin and phenacetin has been tried by Von Noorden during the last two years in a number of affections, including whooping cough, typhoid fever, pneumonia, neuralgias, etc. It apparently possesses the virtues of each of its ingredients, while their drawbacks are neutralized. It was always well tolerated.

119. **Surgical Infections.**—Lexer reviews his experience at Von Bergmann's clinic, and separates the lesions in question into three groups. The first includes snake bites, etc. Absorption of the poison is best averted by constriction above on the limb and excising the wounded part, always using the knife, never the thermocautery. The second group includes anthrax and similar septic processes. Incisions, application of disinfectants and even movements of the muscles of the part may irritate the inflamed tissues and lead to absorption of the germs which otherwise may remain localized. It is sufficient to cover the lesion with a thick layer of salve on a rag and immobilize the part, in a sling, for instance, if the arm be involved. Any one who has seen a facial thrombophlebitis and fatal meningitis develop from a furuncle on the lip which had been pricked and squeezed and otherwise maltreated, will appreciate the benefits of cautious, conservative treatment. The smallest boil may be the source of the severest suppurative osteomyelitis. After opening such a lesion the cavity should be drained and a dry tampon loosely applied. The dry tampon sucks up the secretions and prevents their reabsorption from the wound. The cautery scab has the opposite effect and should be strictly avoided. In incising a large plegmon narcosis is necessary and a constricting bandage around the part. In case of inflammation of a finger, the constriction should be applied at the root and cocain injected into sound tissue, which should always be the rule, never into already inflamed tissue. Small abscesses, etc., are best incised under ethyl chlorid anesthesia. Moist dressings should be rejected except, possibly, for the very mildest affections. Suppuration is more liable and more rapid with than without them, and once established they promote its continuance. Panaritium in the bone is frequently induced by them and poultices are liable to entail extensive necrosis. Suppuration is injurious, as it destroys the tissues. In his third group, the surgeon has long abandoned the hope of destroying the germs in a tetanus wound, bite of a mad dog, or in glanders, by disinfectants: Foreign bodies should be removed from the wound which should be incised freely and kept open under aseptic treatment. This will remove a certain portion of the germs. Excision is better than cauterization for small wounds, but in case of extensive lesions, much soiled, the only treatment is immediate amputation if symptoms of tetanus develop during the first week and they prove violent, even when serum treatment has been promptly applied. In case of a mad dog bite, excision into sound tissue is considered sufficient. In both cases the excision must be smooth and kept open. The conditions are the least promising in acute glanders. Amputation, to be successful, must be done before the lymphatics are involved, and this can occur only in exceptional cases. The abscesses must be incised and every mechanical irritation scrupulously avoided. Curetting the focus has transformed many a mild chronic case into an acute and fatal one.

122. **Calomel Injections in Syphilis.**—Lesser has observed a number of cases and remarks that injections of calomel are liable to cause symptoms of severe intoxication and disagreeable by-effects. They should be reserved for exceptional cases, but are very useful when absolutely indicated.

125. **Anesthesin in Erysipelas.**—Henius states that 25 cases of erysipelas have been treated at Von Noorden's clinic with a 10 per cent. lanolin-vaselin salve of anesthesin, with the result of complete abolition of all pain. No intolerance or by-effects were observed in any case. He adds that he used the anesthesin in two cases of gastric crises in tabes, by intradural injection of a 3 per cent. oil solution, as in spinal cocainization. There was not the slightest anesthesia from it, which confirms Von Noorden's assertion that anesthesin acts only on the nerve terminals and does not affect the nerve trunks.

127. **Radiography Without Plates.**—Kronecker gives some fine radiographs, which were obtained by the use of sensitized silver bromid paper in place of plates. The exposure has to be three or four times as long as when a plate is used, and the exposed parts of the paper must become a shiny black before the picture is complete. But, once taken, the advantages of having the paper instead of a plate are obvious. The radiogram can be taken and completely finished in an hour or so. Another advantage of the paper is that as large an area can be photographed as desired. By combining two of the large sheets it might be possible to take the entire skeleton of an adult at once.

147 (Nos. 2-3.) *Transfusion ved Betaendelser i Peritoneum (in peritonitis). L. Kraft.

139. **Tapeworm in Children.**—Among the 9,000 children admitted to the Luise Hospital at Copenhagen during the last twenty-four years, 43 had tapeworm. The Tenia mediocanellata was found in 37, the solium in 2, and the cucumerina, flavupunctata and the bothriocephalus latus once each. In the above cases 11 were recurrences. Schiödte also adds another series from another hospital, which brings the number to 65 cases, all the patients under 14. The particulars are given

in tabulated form. The exact age was mentioned in 48 cases: It was less than 1 year in 1; between 2 and 3 in 3; between 3 and 4 in 5; between 4 and 5 in 7. The sexes were nearly equally represented. The treatment was not invariably successful. Out of 40 with T. m., only 26 were completely cured. The best results were obtained with rhizoma filicis. One child required five courses before the complete expulsion of the parasite, another four courses, and three, two. Several had had treatment before; the total number of courses was eight in one instance. In one of the unsuccessful cases the child returned for treatment eight years later, proving that the parasite had continued to live for this length of time. The longest tapeworm was expelled from a boy of 13; it measured 14 yards. Another, in a child of 15 months, measured 8 yards. In one case 6 yards were expelled, and two months later 10 yards with the scolex. From this and other cases, he computes the growth of the worm as 10 cm. a day. The appetite in the children was ravenous or defective, or alternating periodically. The general health suffered much from the presence of the parasite and also from the courses of treatment. Some children were much emaciated, and others showed a deficient growth for their age. Nearly all the little patients exhibited pallor of skin and mucosæ, with slight anemia, possibly due to the toxins secreted by the parasite. He mentions that if the after-purge is given too soon, the children are liable to vomit it. He thinks that two or three hours should elapse. His monograph is a very complete study of the subject from all points of view.

141. **Three Gastric Affections.**—One of Guldberg's cases was an hour-glass stomach and gastroptosis, treated by a plastic operation and gastropexy. The second was similar, and was treated in the same way, but required later a gastro-enterostomy with Murphy button and subsequent enteroanastomosis. The button did not pass away, and required removal by a laparotomy thirteen months later. The third patient was treated by gastroenterostomy on account of an ulcer. All the patients were completely cured of their troubles.

144. **Treatment of Puerperal Fever with Artificial Abscesses.**—In the 2 severe cases of septic puerperal fever described, the patients rapidly recovered after the application of turpentine abscesses made according to Fochier's directions.

147. **Transfusion in Peritonitis.**—Kraft has been making an extensive experimental study of the effect of transfusion, that is, intravenous injection of normal saline solution, in artificially induced inflammation of the peritoneum and in health. He describes typical examples out of his experience with about a hundred rabbits. No effect from the transfusion was observed in regard to the absorption or transudation of the peritoneum in health, but it induced transudation whenever the heart or kidneys were insufficient. In case of incipient peritoneal septicemia, absorption by the peritoneum was promoted by the transfusion. It also increased the exudation in case of peritonitis with effusion from any cause. Transfusion is, therefore, indicated in cases of diffuse peritonitis with exudation, as a preliminary to operation, as the exudation is increased and absorption diminished. On the other hand, it is contraindicated in case of circumscribed or migrating peritonitis, as the increased exudation may loosen or detach the adhesions, and thus transform a circumscribed into a diffuse affection. But after an operation, in these cases, when ample outlet has been provided for the secretions and the still sound portion of the peritoneum is protected, transfusion may be useful. It must be cautiously applied, however, as the system would suffer if the resulting exudation were to entail too severe a loss of serum and albumin.

153 Cesarean Section Under Compression of the Aorta. K. Dahlgren.—Kejsarsnitt under aortakompression.

148. **Treatment of Scoliosis.**—Haglund has been traveling in Europe and studying methods of treating scoliosis. The results of the best are far from satisfactory, he thinks, and do not repay the time and efforts. He urges that more attention should be devoted to prevention.

149. **Insanity Among Teachers.**—Lundborg found that 17, or 8 per cent., of the 216 unmarried female insane inmates of the Upsala asylum had been teachers in small schools or private families. He proposes various reforms in the management of the school system to counteract this tendency.

172 Ancora dell' euchinino nell' infezione palustre. M. Capurbano.
173 La faradizzazione nell' occlusione intestinale. G. Fratti. One successful case.
174 Caso di ossurasi cutanea. P. Barbagallo.
175 *Caso di avvelenenamento da sublimato corrosiva. A. Bormans.

167. **Lung Reflex.**—Plessi examined eight patients in regard to the lung reflex described by Adams, after spraying the skin over the lung with ether. He did not find the change in the outline of the lung so marked as Adams claimed. It was never more than 1 or 2 cm., and it is due, he believes, to the contraction of the diaphragm and muscles of the thorax under the influence of the spray.

175. **Recovery from Severe Sublimate Poisoning.**—A girl of 20 took three sublimate tablets of a gram each with suicidal intent. Her friends gave her hot drinks, which helped to dissolve the sublimate, but she vomited one tablet almost entire. None of the drug was found in the stomach when the physician washed it out. He administered white of egg. There was absolute anuria for five days and acute anemia from the severe losses of blood from the necrotic stomatitis, but recovery was rapid and complete.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE AMERICAN YEAR-BOOK OF MEDICINE AND SURGERY FOR 1903. A Yearly Digest of Scientific Progress and Authoritative Opinions in all branches of Medicine and Surgery, Drawn from Journals, Monographs, and Text-Books of the Leading American and Foreign Authors and Investigators. Arranged, with Critical Editorial Comments, by Eminent American Specialists, Under the Editorial Charge of George M. Gould, A.M., M.D. Volume II, General Surgery. Cloth. Price, $3.00 net. Pp. 670. Fully Illustrated. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

CLINICAL TREATISES ON THE PATHOLOGY AND THERAPY OF DISORDERS OF METABOLISM AND NUTRITION. By Prof. Dr. Carl von Noor-

den, Physician-in-Chief to the City Hospital, Frankfort a. M. Authorized American Edition, Translated Under the Direction of Boardman Reed, M.D., Professor of Diseases of the Gastrointestinal Tract, Hygiene and Climatology, Department of Medicine, Temple College, Philadelphia. Part I. Obesity. The Indications for Reduction Cures. Cloth. Pp. 59. Price, $0.50. Part II. Nephritis. Price, $1.00. New York: E. B. Treat & Co. 1903.

A MANUAL OF TOXICOLOGY. A Concise Presentation of the Principal Facts Relating to Poisons, with Detailed Directions for the Treatment of Poisoning; Also a Table of Doses of the Principal and Many New Remedies. By Albert H. Brundage, A.M., M.D., Phar. D., Professor of Toxicology, Physiology and Hygiene in the Brooklyn College of Pharmacy. Second Edition, Revised and Enlarged. Cloth. Pp. 374. Price, $2.00 net. New York: The Henry Harrison Co. London: Bailliere, Tindall and Cox. 1902.

THE PRACTICAL TREATMENT OF STAMMERING AND STUTTERING, with Suggestions for Practice and Helpful Exercises. By George A. Lewis, Originator of the Lewis Phonometric Method. And a Treatise on the Cultivation of the Voice, with a Discussion of Principles and Suggestions for Practice. By George B. Hynson, M.A., Late Principal of the National School of Elocution and Oratory. Illustrated. Cloth. Pp. 415. Price, $3.50. Detroit: George Andrew Lewis. 1902.

PROCEEDINGS OF THE SEVENTEENTH ANNUAL MEETING OF THE CONFERENCE OF STATE AND PROVINCIAL BOARDS OF HEALTH OF NORTH AMERICA. New Haven, October 28 and 29, 1902. Paper. Pp. 192. Providence: Snow and Farnham. 1902.

TWENTY-SEVENTH ANNUAL REPORT OF THE MANAGERS AND OFFICERS OF THE NEW JERSEY STATE HOSPITAL at Morris Plains, for the Year Ending October 31, 1902. Paper. Pp. 116. Trenton, N. J.: John L. Murphy Publishing Co. 1902.

PHYSIOLOGY AT HARVARD. By William Townsend Porter, M.D., Associate Professor of Physiology in the Harvard Medical School. Second Edition. Paper. Pp. 101. Cambridge, Mass.: The University Press. 1903.

A MANUAL OF DENTAL METALLURGY. By Ernest A. Smith, Associate of the Royal School of Mines, London. Second Edition. Cloth. Pp. 294. Price, $2.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

THIRTEENTH ANNUAL REPORT OF THE ST. MARY'S HOSPITAL, Rochester, Minn., for the Year 1902, Conducted by Sisters of St. Francis. Paper. Pp. 32. Rochester, Minn.: Daily Bulletin Print. 1903.

REPORT OF THE BOARD OF MANAGERS OF THE NEW JERSEY SANATORIUM FOR TUBERCULOUS DISEASES, 1902. Paper. Pp. 10. Camden, N. J.: Sinnickson Chew & Sons Co. 1902.

THERAPEUTICS OF INFANCY AND CHILDHOOD. By A. Jacobi, M.D., LL.D. Third Edition. Cloth. Pp. 559. Price, $3.50. Philadelphia and London: J. B. Lippincott Co. 1903.

ANNUAL REPORT OF THE NORTHEASTERN DISPENSARY, Baltimore, Md. Paper. Pp. 12.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending Feb. 21, 1903:

Medical Director J. A. Hawke, retired, detached from Naval Hospital, Mare Island, Cal., and ordered home.

Medical Inspector M. H. Simons, ordered to Washington, February 24, for examination for promotion, and thence to Naval Hospital, Mare Island, Cal.

Surgeon H. B. Fitts, detached from the Naval Hospital, Sitka, Alaska, and ordered to the *Pensacola*.

A. A. Surgeon H. T. Nelson, Jr., ordered to the Marine Barracks, Sitka, Alaska.

Medical Inspector D. N. Bertolette, detached from the *New York*, and from duty as fleet surgeon of the Pacific Station, and ordered home to wait orders.

Surgeon D. O. Lewis, detached from the *Pensacola* and ordered to the *New York* for duty as fleet surgeon of the Pacific Station.

A. A. Surgeon G. C. Grieve, ordered to the Navy Yard, Boston.

A. A. Surgeon J. R. Dykes, ordered to the *Franklin*.

A. A. Surgeon V. Dabney, ordered to the *Pensacola*.

A. A. Surgeon T. C. Blackburn, ordered to the *Culgoa*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Feb. 19, 1903:

Surgeon P. C. Kalloch, to proceed to Augusta, Me., for special temporary duty.

Surgeon S. D. Brooks, to assume temporary command of the Portland, Me., quarantine station during the absence of Surgeon P. C. Kalloch.

Asst.-Surgeon Edward Francis, relieved from duty in the Hygienic Laboratory, and directed to proceed to Mexico and Durango, Mexico, for special temporary duty.

Asst.-Surgeon W. K. Ward, granted leave of absence for four days from Feb. 13, 1903, under Paragraph 191 of the regulations.

A. A. Surgeon J. T. Bullard, granted leave of absence for 30 days from February 13.

Pharmacist E. M. Holt, to proceed to Louisville, Ky., and report to P. A. Surgeon G. B. Young, chairman of board of examiners, to determine his fitness for promotion to the grade of pharmacist of the second class.

Pharmacist G. A. Morris, granted leave of absence for seven days from Feb. 11, 1903, under Paragraph 210 of the regulations.

PROMOTION.

P. A. Surgeon G. M. Guiteras, commissioned as surgeon to rank as such from Dec. 13, 1902.

BOARD CONVENED.

Board convened at the marine hospital, Louisville, Ky., for the purpose of examining Pharmacist E. M. Holt, to determine his fitness for promotion to the grade of pharmacist of the second class. Detail for the Board: P. A. Surgeon G. B. Young, chairman; Asst.-Surgeon T. D. Berry, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Feb. 20, 1903:

SMALLPOX—UNITED STATES.

California: Fresno, Jan. 1-31, 15 cases; Los Angeles, Jan. 31-Feb. 7, 2 cases; Sacramento, Jan. 31-Feb. 7, 1 case; San Francisco, Jan. 24-Feb. 8, 13 cases.

Colorado: Jan. 31-Feb. 7, Colorado Springs, 1 case; Denver, 8 cases.

Illinois: Belleville, Jan. 31-Feb. 7, 1 case; Galesburg, Jan. 31-Feb. 14, 7 cases.

Indiana: Elwood, Feb. 8-15, 3 cases; Evansville, Jan. 31-Feb. 14, 9 cases, 1 death; Indianapolis, Jan. 31-Feb. 14, 121 cases, 24 deaths; South Bend, Jan. 31-Feb. 7, 1 case.

Iowa: Davenport, Jan. 31-Feb. 14, 12 cases; Ottumwa, Jan. 8-10, 1 case.

Kentucky: Lexington, Jan. 31-Feb. 14, 4 cases; Newport, Jan. 31-Feb. 14, 2 cases.

Louisiana: New Orleans, Jan. 31-Feb. 12, 3 cases, 2 imported.

Maine: Biddeford, Feb. 7-14, 12 cases; Eastport, Feb. 7-10, 13 cases; Portland, Jan. 31-Feb. 7, 1 case.

Maryland: Baltimore, Feb. 7-14, 1 case.

Massachusetts: Boston, Feb. 7-14, 4 cases, 2 deaths; Haverhill, Feb. 7-14, 1 case; Lynn, Jan. 31-Feb. 7, 1 case.

Michigan: Detroit, Feb. 7-14, 38 cases, 1 death; Flint, Jan. 31-Feb. 14, 4 cases; Grand Rapids, Feb. 7-14, 10 cases; Port Huron, Feb. 7-14, 12 cases.

Nebraska: Omaha, Jan. 31-Feb. 7, 7 cases.

New Hampshire: Manchester, Jan. 31-Feb. 7, 10 cases.

New Jersey: Camden, Feb. 7-14, 1 case; Jersey City, Feb. 8-15, 3 cases, 1 death; Newark, Feb. 7-14, 1 case; Plainfield, Feb. 7-14, 1 case, imported.

New York: New York, Feb. 7-14, 3 cases.

Ohio: Chillicothe, Jan. 24-31, 8 cases; Feb. 7-14, 3 cases; Cincinnati, Feb. 6-13, 7 cases; Cleveland, Jan. 31-Feb. 14, 16 cases, 4 deaths; Dayton, Feb. 7-14, 1 death; Hamilton, Jan. 31-Feb. 14, 2 cases; Toledo, Jan. 31-Feb. 14, 15 cases, 1 death.

Pennsylvania: Butler, Jan. 17-Feb. 7, 2 cases; Erie, Jan. 31-Feb. 7, 4 cases; Johnstown, Jan. 31-Feb. 14, 5 cases, 3 cases imported; Philadelphia, Feb. 7-14, 30 cases, 2 deaths; Pittsburg, Jan. 31-Feb. 7, 18 cases, 3 deaths; York, Jan. 1-31, 1 case.

South Carolina: Charleston, Jan. 31-Feb. 7, 14 cases, 1 death.

Utah: Ogden, Jan. 1-31, 17 cases; Salt Lake City, Jan. 31-Feb. 7, 21 cases.

Wisconsin: Milwaukee, Jan. 31-Feb. 14, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Jan. 17-24, 7 cases.

Barbados: Jan. 16-30, 8 cases.

Belgium: Jan. 17-24, Antwerp, 4 cases, 2 deaths; Brussels, 1 death.

Canada: Amherstburg, Jan. 24-31, 1 case; Winnipeg, Jan. 31-Feb. 7, 1 case.

Canary Islands: Las Palmas, Jan. 17-24, 33 cases, 2 deaths.

Colombia: Cartagena, Jan. 26-Feb. 1, 1 death.

Ecuador: Guayaquil, Jan. 24-31, 1 death.

France: Rhelms, Jan. 18-24, 1 case.

Germany: Hamburg, Jan. 24-31, 1 case; Leipsic, Jan. 17-24, 1 death.

Great Britain: Dublin, Jan. 17-31, 1 case, 1 death; Leeds, Jan. 24-31, 4 cases; London, Jan. 24-31, 6 cases; Manchester, Jan. 17-31, 27 cases, 1 death; Nottingham, Jan. 17-31, 14 cases.

India: Bombay, Jan. 6-20, 61 cases; Calcutta, Dec. 13-Jan. 17, 2 cases; Madras, Dec. 20-26, 2 deaths.

Italy: Palermo, Jan. 10-31, 15 cases, 5 deaths.

Mexico: City of Mexico, Jan. 26-Feb. 1, 4 cases, 4 deaths.

Russia: Moscow, Jan. 10-24, 7 cases, 4 deaths; Odessa, Jan. 17-24, 2 cases; St. Petersburg, Jan. 10-24, 71 cases, 21 deaths.

Straits Settlements: Singapore, Dec. 27-Jan. 3, 3 deaths.

Turkey: Constantinople, Jan. 18-25, 1 death.

SMALLPOX—INSULAR.

Philippines: Manila, Dec. 13-27, 2 cases.

YELLOW FEVER.

Colombia: Panama, Jan. 26-Feb. 9, 5 cases, 2 deaths.

Ecuador: Guayaquil, Jan. 17-24, 20 deaths.

Mexico: Vera Cruz, Jan. 31-Feb. 7, 2 cases, 2 deaths.

CHOLERA—INSULAR.

Philippines: Manila, Dec. 13-27, 16 cases, 10 deaths; Provinces, Dec. 13-27, 1,130 cases, 813 deaths.

CHOLERA—FOREIGN.

India: Bombay, Jan. 9-20, 1 death; Calcutta, Dec. 13, 152 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Feb. 5, 1 death.

Philippines: Manila, Dec. 13-27, 1 death.

PLAGUE—FOREIGN.

India: Bombay, Jan. 6-20, 818 deaths; Calcutta, Dec. 13-Jan. 17, 85 deaths; Karachi, Dec. 28-Jan. 11, 53 cases, 52 deaths; Madras, Dec. 20-26, 1 death.

Mexico: Mazatlan, Feb. 4-12, 11 new cases, 23 deaths.

BACTERIOLOGIC EXAMINATION OF THE BLOOD DURING LIFE IN SCARLET FEVER WITH SPECIAL REFERENCE TO STREPTOCOCCEMIA.

FROM THE MEMORIAL INSTITUTE FOR INFECTIOUS DISEASES.

LUDVIG HEKTOEN, M.D.

CHICAGO.

In this article are presented the results of a bacteriologic examination of the blood during life of cases of scarlet fever with especial reference to general streptococcus infection in this disease.

FREQUENCY OF STREPTOCOCCI IN FATAL SCARLATINA.

Streptococci have played a prominent part in the bacteriology of scarlet fever since the earliest application of bacteriologic methods to its study. Their importance has grown as the observations have multiplied, and many now regard streptococci as an essential factor in the scarlatinal process. Among the earlier observations concerning general streptococcus infections in scarlet fever are those of Crooke, Löffler, Friedländer, Fränkel and Freudenberg, Heubner and Bardt, Lenhartz and others, who found virulent streptococci in the internal organs and sometimes in the joints of victims of this disease. All these investigators appear to have regarded the streptococcus infection as entirely secondary in its character, the principal point of entrance being the throat.[1]

Babes[2] found streptococci in the internal organs of seventeen fatal cases of scarlatina. In fourteen instances of scarlatinal nephritis streptococci were present in the kidney in pure culture. In various articles Babes has suggested that streptococci are the cause of scarlatina. His material certainly justifies the conclusion that streptococci of varying virulence cause the larger part of the secondary infections in scarlet fever.

Streptococci have been found, in a large proportion of the cases examined, in the urine of scarlet fever patients by Courtois,[3] Lewis and others, and more frequently in albuminous than in non-albuminous urines.

Marie Raskin[4] made very extensive studies in the bacteriology of scarlet fever and its complications. She failed to find streptococci in the blood of 64 cases, but isolated it four times from the skin in 20 cases. But in 31 cases with serious complications of various kinds she found streptococci present in the pus, generally in the internal organs, occasionally in the blood. In two cases of scarlatina fulminans without complications streptococci were found in the blood. The streptococcus she found formed long twisted chains in bouillon which remained clear except for some sediment, and she regarded it as a form of *Streptococcus pyogenes* and as the most important cause of the complications of scarlet fever. In another article[5] she speaks of a micrococcus of irregular form and size, growing like streptococcus in gelatin and agar, and found in the blood and organs during the first four days of the disease. In the blood the organism was found within the leucocytes in diplococcus form, one coccus being larger than the other. Unfortunately the available abstract is too fragmentary to justify any conclusions as to the real nature and significance of the coccus.

R. M. Pearce[6] records the results of the examinations of 23 fatal cases of scarlet fever. "Of the 11 cases in which there was a general infection, the streptococcus was found in 9. In 6 of these it occurred alone, and in 3 associated with the *Staphylococcus pyogenes aureus*. Infection with the *Staphylococcus pyogenes aureus* alone occurred in one case, and with the pneumococcus alone in one case." *Streptococcus pyogenes* was found also to be the most frequent cause of the secondary inflammatory lesions in this series. Pearce regards the streptococcus infections, local as well as general, in scarlet fever as secondary in their nature, and he considers the streptococcus found in his series as identical with *Streptococcus pyogenes*.

Wright,[7] in 11 fatal cases, notes a general streptococcus infection in 4. Baginsky and Sommerfeld[8] found streptococci in the heart's blood and internal organs in every one of 82 fatal cases of scarlet fever, including several in which death occurred early and in which gross secondary lesions had not developed. They were unable to differentiate the streptococci isolated from ordinary pathogenic streptococci. A high degree of virulence for rabbits could be created readily by repeated passages through this animal. The serum of convalescents from scarlet fever had no demonstrable agglutinating effect on streptococci from the victims of the disease; nor did the serum of convalescents have any definite protective action in rabbits injected with such streptococci. In other words, the organism did not appear to possess any specific properties of any kind, demonstrable by these methods. Nevertheless, Baginsky and Sommerfeld contend that this streptococcus plays a specific rôle in scarlet fever and that all the phenomena of the disease are explainable by the distribution of the cocci in the tissues and by intoxication with their products. While scarlet fever never transfers erysipelas or sepsis, but only scarlatina, yet streptococci are constant in scarlatinal angina; they cause a general infection in all fatal cases of scarlatina, even the uncomplicated, and they have been found in the blood of scarlatinal patients during life. This seems to be the line of reasoning that leads to the conclusion that scarlet fever is a streptococcus disease.

Slawyk's[9] observations are interesting. Of 98 fatal cases of scarlet fever 52 (52.6 per cent.) yielded bacteria on examination of the blood after death. Streptococci were found 39 times, streptococci and staphylococci 6 times, staphylococci 3 times and pneumococci 4 times. He examined the blood during life in 72 cases with positive results in 7, streptococci being found 4 times and staphylococci 3 times. These 7 children died and in all the same bacteria were found after death. In these cases the blood was taken from the lobe of the ear and the small amount of blood thus obtainable may have reduced somewhat the number of positive cases. Slawyk regards the streptococcus invasion as secondary because of its absence in a goodly number of cases even after death; because in 82 per cent. of the cases in which it was found there existed grave ulcerative complications through which invasion readily could take place; and because streptococci were absent in those cases that died in the first three days of the disease. Present on the tonsils of healthy children he believes the oropharyngeal cavity to be the common point of entrance for streptococci in scarlet fever, the virus of which either increases their virulence or decreases the resistance of the tonsillar tissue. In measles and diphtheria he found streptococci in the blood in 22 and 20 per cent. of the fatal cases respectively.

Based on the negative result of a careful bacteriologic examination of the internal organs of a child that died 48 hours after the onset of scarlatina, Böhm[10] categorically denies all etiologic relationship between scarlet fever and streptococci.

Gordon[11] isolated a streptococcus from 10 fatal cases. The claim that this streptococcus is distinct and that it merits the designation *"Streptococcus scarlatinæ"* as yet seems to rest on rather slender basis. And Moser[12] isolated streptococci from the heart's blood in 63 of 90 cases of scarlet fever.

The foregoing summary shows the great frequency of streptococcus infection in fatal cases of scarlatina. It certainly lies near at hand to conclude that scarlet fever without streptococcus invasion would lose half its terrors even if one is not willing to accept the view that scarlatina is a streptococcus disease, caused by a specific streptococcus, a contention that is without definite proof though some facts may be adduced in its favor. Under these circumstances it would seem desirable to learn more about the presence or absence of streptococci in the blood of non-fatal, mild as well as severe, complicated as well as uncomplicated, cases of scarlatina. Comparatively little work has been done on this phase of the problem, and that is mostly of a rather fragmentary character.

BACTERIOLOGIC STUDIES OF SCARLATINAL BLOOD DURING LIFE.

Lemoine[13] found the streptococcus in the blood during life in 2 of 39 cases. Klein[14] was one of the first to describe cocci as the cause of scarlet fever. For years he has upheld as this cause *Streptococcus scarlatinæ* or *Streptococcus conglomeratus,* which, so he claims, was described by himself and Kurth.* Klein claims, further, that this organism does not occur in healthy persons or such as have angina not scarlatinal. He isolated it from the blood of 4 cases of 11 scarlet fever between the third and sixth day.

D'Espine and Marignac isolated from the blood of the finger of a scarlet fever patient a streptococcus. The case being typical and without complications in the usual sense, d'Espine[15] claims that the streptococcus was the cause of the scarlet fever.

Mery[16] isolated from the blood of a scarlet fever patient a streptococcus that proved refractory to Marmorek's antistreptococcus serum.

Seitz[17] examined the blood bacteriologically in the early stages of 12 cases of scarlatina, using about 1 c.c. of blood on various media. Streptococci developed in the cultures from one case that subsequently proved fatal. He also found streptococci in the internal organs of two fatal cases.

Reference has been made to the fact that Slawyk made cultures of the blood in 72 cases, the blood being obtained by puncture of the lobe of the ear; of the 7 positive results 4 concerned streptococci and 3 staphylococci. All of the 7 cases died and the same organisms were recovered from the internal organs after death.

Hlava[18] has described recently a streptococcus that he finds with special frequency in the acute eruptive diseases. In many respects this streptococcus resembles the ordinary pathogenic streptococci, especially *Streptococcus conglomeratus,* but Hlava claims for it the individual peculiarity of forming crumbling masses in certain media containing saccharose (Zopf's bouillon, saccharose-agar), the masses consisting of short chains of atypical and pleomorphic cocci embedded in homogeneous membrane. The organism is said by Hlava to be of feeble virulence, and that only when grown in fluid human serum. Much further work is necessary before this streptococcus, which Hlava designates as *Leuconostoc hominis* because of its resemblance to *Leuconostoc mesenteroides,* can be accepted as a definite and distinct form. Because of its frequency in scarlatina Hlava is led to say: *"Der Leuconostoc spielt enschieden eine wichtige Rolle in der Pathogenese der Scarlatina."* He demonstrated its presence in the blood during life in 6 cases of scarlet fever.

MATERIAL AND TECHNIC.

The cases of scarlet fever that furnished the material for the investigation, the results of which are now presented, occurred partly in the hospital of the Memorial Institute for Infectious Diseases, partly in the Cook County Hospital. I am indebted for courtesy and aid in various ways to Drs. Frank Billings, James B. Herrick and W. L. Baum, and to members of the resident staffs of the Cook County and Presbyterian hospitals.

The blood for the cultures is secured by puncture of some vein at the elbow after careful disinfection of the skin. This is the best method to secure blood for bacteriologic work. Glass syringes with platinum-iridium needles are used. In the case of very young children it may be difficult to puncture accessible veins, and in a relatively small number of instances the effort to secure blood may have to be abandoned. In no case has any evil resulted from the punctures, all of which have healed without the faintest indication of local reaction. The pain of the puncture is insignificant; momentary

* It will be recalled that Kurth (Centralbl. f. Bakt., 1892, xi, 503-509) has made one of the most successful efforts at differentiation of the streptococci by accurate study of their different forms of growth in bouillon and of the sediment that forms therein. From the tonsils in scarlet fever he isolated a form that produces granular or scaly coherent masses composed of very long, interwoven chains with only a few free cocci. This is his *Streptococcus conglomeratus,* which may occur also in the internal organs of fatal cases of scarlet fever. In Kurth's experience it was never absent from the surface of the tonsils. It may be associated in scarlet fever with other streptococci. *Streptococcus conglomeratus* nearly always kills white mice when inoculated at the root of the tail. It may remain viable for as long as six weeks or so when dried, and, while the question of its etiologic rôle had to be left open, Kurth points out that the transmissibility of scarlatina corresponds well with viability of *Streptococcus conglomeratus.*

washing the skin with 5 per cent. solution of carbolic acid seems to deaden acute sensation somewhat; the drawing of the blood so rapidly as to cause collapse of the vein seems to give considerable pain.

In the early part of the work white staphylococci appeared in the cultures much more frequently than later. White staphylococci have appeared in altogether about 18 flasks and 7 of these occurred among the cultures from the first 10 cases. This certainly speaks in favor of accidental contamination, and it is likely that in spite of painstaking precautions occasional contamination will take place either from the air or by the needle picking up cocci from the skin. As it has been impossible to differentiate the white staphylococci developing from time to time in the flasks from the vulgar staphylococci of the skin and air, it has seemed best, at least for the present, to pay no attention to these organisms. Of course, streptococci may occur occasionally on the skin in scarlet fever. This, however, probably is so infrequently the case that accidental contamination of blood cultures from this source may be left out of consideration. This is probably also a fair view to take of the rôle of the air as a source of accidental contamination with streptococci. In bacteriologic examinations of the skin in some 30 cases of scarlet fever by Mr. Dreyer, he did not encounter streptococcus, and Dr. Weaver met it only once in 18 cases.

In most of the cultures in this series quite large quantities of blood have been used, 0.5 to 1 c.c. in each flask of 150 or 100 c.c. of medium. Usually two flasks or more have been inoculated in each case. The principal reason for using large quantities of blood was to increase as much as possible the chances for positive results in case but few bacteria might be present. The media used were glycerin bouillon, plain bouillon, ascites bouillon (peptone bouillon 2 parts and ascites fluid one part), glucose bouillon and milk. From time to time the adaptability of the media used for streptococci has been controlled carefully. After 48 hours or so in the incubator (mostly under aërobic conditions) subcultures on solid media and stained smear preparations have been made in most of the cases even though there was no definite evidence of growth in the original cultures. When growth was evident plates were made to secure pure cultures.

RESULTS.

The principal details of the cases giving positive results are given in the accompanying table. In many of the cases smears of the blood were examined for bacteria, but in every case so far with negative outcome. In smears from the cultures in which streptococci developed diplococci and short chains were seen often within cells, but this need not necessarily indicate that the cocci occupied an intracellular position in the circulating blood. In no case was hemolysis of human corpuscles *in vivo* recognized, but this was not looked for systematically in all cases, and certainly not with sufficient care (centrifugalization of the whole blood so as to secure clear serum) in the cases that proved to give streptococci in the cultures of the blood. We hope to give closer attention to this point in the future.

In all cases giving streptococci, *Staphylococcus aureus*, or typhoid bacilli pure cultures developed in practically every instance.

Typhoid Bacillemia.—In two cases (only one of which is included in the table) the routine bacteriologic examination of the blood discovered the presence in it of typhoid bacilli at a period so early in the development of the disease that suspicion had not yet been directed to typhoid fever. In one of the cases the typhoidal attack began as the scarlet fever subsided; in the other case the typhoid fever developed in a woman admitted to the scarlet fever ward because of a slight general eruption, which did not prove to be scarlatinal. A third case of this sort has just been observed. In these cases we have a good example of the diagnostic usefulness of bacteriologic examinations of the blood. In both typhoid bacilli were demonstrated some time before the appearance of agglutinins in the blood.

Streptococcemia.—It is not the intention now to discuss the question of the unity or multiplicity of pathogenic streptococci. All the strains isolated in this series, except the one from Case 60, correspond to *Streptococcus longus,* most of them showing pronounced conglomerate growth. Some of the more important facts are given in the following abstracts of the records:

The streptococci isolated on the third and eighth days of the disease in Case 11, appears to be identical. Both give a moderately heavy, crumbling sediment in bouillon, and coagulate and acidify milk promptly. One c.c. of a 24-hour bouillon culture injected intravenously in a rabbit weighing 1,720 grams caused death in 4 days. This virulence was soon lost. On the fifteenth day of the disease the serum of the patient had no marked restraining influence on this streptococcus, nor did the serum of another case of scarlet fever. The streptococcus does not grow in filtrates of its own cultures. Such filtrates remain sterile also when inoculated with streptococci from some of the other cases.

Judging from the temperature curve, pulse record and general course, it can not be said that the streptococcemia in this case produced very marked clinical symptoms. There were no complications.

The streptococcus in the cultures made on the fifth day of the disease from the blood of Case 15 forms a sand-like sediment in bouillon, the particles being composed of conglomerate masses of cocci. It acidifies and coagulates milk. It does not grow in its own filtrates or in the filtrates of cultures of other streptococci in this series. The filtrate of bouillon cultures causes hemolysis of dog's corpuscles. One c.c. of bouillon cultures three

Table Showing Positive Results of Bacteriologic Examination of Blood in Scarlet Fever During Life.

days old kills rabbits in five days after intravenous injection and causes hemolysis *in vivo*. The organism grew well in the serum of the case from which it was isolated and also in that of another case of scarlet fever. Clinically this case showed no glandular enlargement, but there were definite indications of inflammation in the wrist, shoulder and ankle joints which subsided rapidly.

The streptococci isolated from the culture of the blood of Case 17, on the second and sixth day of the disease are identical and form granular masses in bouillon. There is no growth in filtrates of streptococcus cultures. Two c.c. injected intravenously in a rabbit weighing 1,720 grams caused death in seven days. There were in this case severe throat symptoms and also swelling and tenderness of the wrist joints.

In Case 33 the cultures from the blood in ascites bouillon contained atypical streptococcal forms, but subcultures were not obtained. In the cultures made in ascites bouillon from the urine of the same patient there developed a feeble growth of streptococci with an unusual number of swollen, atypical and bacillary forms similar to those described by Ohlmacher,[19] and also noted by Hilbert[20] in his work on streptococci in the normal tonsils, as well as by others.[21]

In Case 60 the cultures on both the second and fourth day yielded pure growths of a streptococcus that was provided with a mucoid capsule. This coccus grew like ordinary streptococci on most media, but on Löffler's serum it produced rust-colored spots. This pigmentation disappeared after the second generation. Its pathogenic powers were not tested. The clinical course in this case was very mild, the temperature falling to normal on the fifth day. No complications.

In Case 72 the cultures made on the fourth day of the disease remained sterile. Three flasks were inoculated. On the twenty-eighth day a pure growth of streptococci was obtained. This coccus has the following characteristics: Abundant flocculent growth in the fluid part of Löffler's serum and in the lower parts of peptone bouillon ascites fluid tubes; milk acidified but not coagulated; in glucose bouillon crumbling masses formed at the bottom. The principal facts in the history of this case are as follows: From the time of entrance the patient was for many days more or less delirious; later on he lapsed into stupor and unconsciousness, the clinical picture being distinctly that of sepsis. In the early stages there was an intense pharyngitis and tonsillitis with large swellings of the cervical glands. Otitis developed and for a time there was tenderness over the mastoid processes. During the entire illness there was a marked leucocytosis which gradually passed away. There was no evidence of joint infections or of secondary internal foci.

In Case 80 the cutlures made in glucose bouillon remained sterile. At the same time as the cultures were made 1 c.c. of blood was mixed with 9 c.c. of ascitic fluid, first heated to 55 C. for 45 minutes, and placed in a collodion sac. At the end of 24 hours the fluid within and without this sac appeared sterile and the sac was inserted into the abdomen of a rabbit, where it remained for one month without apparent detriment to the animal. When removed the contents of the sac were milky and smears showed minute coccoid bodies not staining readily by methylene blue. The fluid in the sac was alkaline in reaction. Cultures were made on a large number of media, and on most of the tubes there developed a streptococcus, like *Streptococcus conglomeratus*, but only of small virulence that was increased by repeated passage through rabbits. This coccus grew readily in conglomerate masses in filtrates of its own cultures in milk and glucose bouillon, the reaction being acid to litmus. In the early cultures in milk especially many atypical and irregular forms were observed in the smears. Clinically the case was free from complications.

The streptococcus cultures from Cases 57, 21 and 14 correspond to those of *Streptococcus conglomeratus*. Those from Cases 14 and 41 caused the death of rabbits on intravenous injection of 0.5 c.c. or more: there was hemolysis of the red corpuscles in the rabbit injected with the coccus from Case 41. In Case 52 distinct streptococcal chains developed in the original cultures on the fourth day of the disease, but subcultures did not develop.

The evanescent character of the streptococcemia in some of the cases of this series makes it not unlikely that in many cases it may have escaped detection, especially in the younger patients in whom it was deemed best to make but one venous puncture. Perhaps this may serve also to account in some degree at least for the relatively greater number of positive results in the older patients.

Table Showing the Ages of the Cases.

Age.	1-5	6-10	11-15	16-20	21-25	26-30	31-43	Total
Total number...	9	32	11	10	21	12	5	100
Streptococci in. .		3	2	1	4	1	1	12

It might be said, too, that perhaps streptococci were not detected oftener because the blood cultures were not made early enough in the attack. It could be answered that in three positive cases the first cultures gave negative results, while later cultures gave positive; further, that of 10 cases examined on the first day only one gave growths.

Table Showing the Days of the Attack When Cultures Were Made.

Day.	1	2	3	4	5	6	7	8	9	10	Later or Unknown	Total
Total number...	10	14	24	17	14	5	4	4	1	1	6	100
Streptococci in first culture..	1	2	1	1	2	..	1	..	..	..	..	8
Streptococci in second culture	..	..	1	..	..	1	..	..	..	..	1	3
Streptococci in third culture.	..	..	..	..	1	..	..	..	..	..	..	1

Undoubtedly the number of positive results would increase the more frequently from the earliest period the cultures in the single cases could be made. On account of the well-known sensitiveness of streptococci special care must be had always with respect to the media used. In work of this kind positive results are more valuable in the forming of definite conclusions than negative.

Table Showing General Character of the Cases in This Series.

	Mild.	Mod.	Severe.	Severe.	Fatal.	Total.
Total number.....	45	40	11	4	100	
Streptococci in.....	4	5	3	..	12	

This summary shows that the relatively largest number of streptococcal growths were obtained from the more severe cases. Two of the fatal cases are accounted for further on; in the other two there was no postmortem examination and in each case of these there was but one set of blood cultures made.

Genesis of Streptococcemia.—In many of the cases giving streptococci in the cultures it seems to concern a streptococcus bacteriemia (septicemia) without localizations in different parts of the body. This form of bacteriemia without metastases is referred to by Monod and Mascaigne,[22] and more recently again by Kretz,[23] as common in the eruptive diseases and as only poorly understood, being more marked in some epidemics than in others. No doubt continued routine bacteriologic examinations of the blood in these and other diseases will prove the best source for light on the relations of this

bacteriemia without metastases to the severity of the clinical symptoms as well as on other points not now clearly understood.

The investigations of Hilbert[24] and others show that pathogenic streptococci—*Streptococcus longus*—are constant inhabitants of the normal throat, especially the surface of the tonsils. On this account some, like Hilbert, would deny streptococci all importance in the etiology of anginas, but it is difficult to go so far in view of the great increase in the number of streptococci in anginas of various kinds, especially the scarlatinal, a fact definitely established in the cases of this series by Dr. Weaver in this institute. At all events the conditions of the throat in scarlet fever would seem to offer excellent opportunities for general streptococcus invasion either directly by entrance into the blood or indirectly by way of the lymphatics and lymph nodes. The exact mechanism of the general infection is not easily unraveled. It lies too near at hand to assume that it may depend on the loss of bacteriolytic complements of serum. Indeed, this assumption has been made by some who would explain in this way the frequency of streptococcus infection in chronic diseases of various kinds because the serum in such diseases may show a loss of bacteriolytic complements for colon bacilli and typhoid bacilli; but normal human serum has no appreciable bactericidal action on streptococci, so far as this can be demonstrated by the usual methods for such purposes, and streptococcemia is, of course, not to be explained by the loss of certain properties the blood does not possess normally. Experiments made in conjunction with Dr. Weaver show, furthermore, that the serum of cases of scarlet fever of moderate severity does not lose any bactericidal effect on typhoid bacilli, a fact that still further disproves the inference that the loss of bacteriolytic serum complements is responsible for streptococcus infections. It is not the intention to discuss now the relations to streptococcus infection of the leucocytes and of phagocytosis on which Denys, Bordet and Marmorek lay so great a stress. Suffice it to say that in general human tissues appear to be favorable soil for the growth of streptococci; indeed, of all animals Marmorek regards man as the most susceptible for streptococci. There is reason to believe, too, that streptococci grow in virulence when introduced into the human body. In connection with this it is interesting to note, as first shown by Marmorek, that streptococcal virulence—a most changeable quantity—is best preserved in a medium of human serum one part and peptone bouillon two parts. Given then a normally feeble general resistance to streptococci and specially favorable conditions for their multiplication in the throat and on the tonsils in scarlet fever, it need not be an unusual event for streptococci to enter the blood either in small quantities as only transitory sojourners there or increasing in number and virulence to cause the most severe general infections. That this is the case is indicated by the results in this series in which streptococci are shown to have appeared in the blood to such an extent as readily to be demonstrable by inoculating one or two cubic centimeters into bouillon or similar medium, and that in comparatively mild cases in which the normal or uncomplicated course of the disease was not modified to any extent (Cases 14, 27, 33, 60). In other cases, again, the streptococcus invasion was associated with more severe symptoms and a more protracted course (11, 15, 17, 72). Case 72 may be taken as an example of a severe type of streptococcus infection in scarlet fever, terminating in recovery.

The fact that spontaneous recovery may take place in streptococcus bacteriemia, even when severe and long continued, naturally tends to make one somewhat skeptical in regard to the actual benefit of antistreptococcus serum in similar cases. Since the introduction of bacteriologic blood examinations during life, observations have been made that show, as did Petruschky in one of the earliest studies of this kind, that recoveries in various forms of bacteriemia are not so very rare. Bertelsmann[25] reports 47 cases of surgical bacteriemia examined bacteriologically during life; in 28 of these it concerned streptococci, and 13 of these were all that proved fatal. In 2 cases the bacteriemia appeared transitory, but recovery took place in cases whose blood yielded as many as 435 colonies on mixing 15 c.c. with agar and pouring into plates.

Influenza Bacillemia.—While streptococci no doubt are the most common agents of general infection in scarlet fever and other diseases of the same group, the investigation of Jehle seems to show that under certain conditions other bacteria also may find open doors, so to speak, to general invasion in these diseases. Jehle[26] found the bacillus of influenza so frequently in the blood of fatal cases of scarlet fever (22 times in 48 cases), measles (15 times in 23 cases) and varicella (5 times in 9 cases) as compared with non-eruptive diseases, that he believes the exanthemas in some way favor the general infection with this bacillus when it is present on the tonsils or in the bronchial exudate. This form of secondary infection may cause a high mortality. In scarlet fever influenza bacillemia may occur even before the rash breaks out. In this work not a single case of this form of secondary invasion has been encountered, although it has been kept in mind almost from the first; the mixing directly of considerable quantities of blood with glycerin, glucose and ascites bouillon would seem to offer proper conditions for the growth of the bacillus of influenza. It must be borne in mind, however, that during the past year influenza has not been especially prevalent in Chicago. Not a single case of the disease has been recognized among the cases of scarlet fever composing this series nor in the wards occupied by them.

Staphylococcemia.—In the two fatal cases of this series *Staphylococcus aureus*, and not streptococci, developed in the cultures made during life. In both cases it concerned pure cultures.

Case 68.—Man, 21, admitted to the hospital of the Memorial Institute for Infectious Diseases on the 9th day of a severe attack of scarlet fever. There was beginning desquamation; swelling and erosions of lips and nostrils; purulent conjunctivitis, pharyngitis and otitis; swelling and tenderness on both sides of the neck; heart and lungs normal; spleen palpable. Violent and nearly continuous delirium set in. The cultures from the pharynx showed streptococci and staphylococci, those from the ears streptococci. Lobular pneumonia developed and death took place on the 16th day of the attack. There was no leucocytosis but rather leucopenia—9,500, 3,300 and 5,200 on the 10th, 12th and 15th days respectively.

The cultures of the blood made on the 9th day of the disease, the day he entered the hospital, all remained sterile. Three days later new cultures developed rapidly a liberal growth in pure form of *Staphylococcus aureus*. In both the flasks there were seen the day after inoculation numerous irregular masses, much like the plugs of exudate in lobar pneumonia, scattered over the bottom and clinging to the sides, each mass being surrounded by a circle of hemolysis. This coccus produced a funnel-shaped liquefaction of gelatin, coagulated and acidified milk, and formed golden-yellow pigment, especially on potato and blood serum. Blood from this case preserved in glass tubes with bouillon in proportion of 2 to 8 also underwent hemolysis.

Anatomic Diagnosis (Dr. Robinson):—Desquamation of scarlet fever; pustules on arms, neck and legs; bronchopneumonia; pulmonary infarction; ulcerative pharyngitis; suppurative otitis; acute splenic swelling.

Cultures made from the heart's blood at the time of the autopsy showed *Staphylococcus aureus* only; those from the lungs showed *B. mucosus capsulatus* and *Staphylococcus aureus* as did also the cultures from the bone marrow. The liver contained *B. mucosus capsulatus*. The kidney, brain and spleen were sterile.

CASE 81.—Boy, age 7, admitted on the 7th day of the attack, much emaciated, throat ulcerated, cervical glands enlarged. Beginning desquamation. Pulse weak and intermittent. Bloody discharge from nose and mouth. Semi-unconscious. Death on the 11th day. Leucocytes on the 10th day, 32,000.

The cultures from the blood made on the 7th day of the disease gave pure growths of *Staphylococcus aureus*. The cultures made two days later showed cocci in the smears, but all subcultures remained sterile.

Anatomic diagnosis.—Scarlatinal desquamation; pharyngeal necrosis and ulceration; acute cervical lymphadenitis; splenic swelling; acute renal degeneration; enlargement of intestinal lymph nodes and of mesenteric glands; esophageal ulceration; multiple purulent arthritis; pleural adhesions. The cultures made at the autopsy gave the following: Plate cultures from blood, bile and pus in the left knee-joint remained sterile. The spleen gave streptococcus and colon bacillus; the liver streptococcus; the kidney colon bacillus. This streptococcus grows in conglomerate masses in bouillon.

In this interesting case it looks as if the staphylococci in the blood on the seventh day died out completely. There was, however, a coincident or subsequent, more likely the latter, streptococcus infection, as shown by the presence of this organism in the liver and spleen at the autopsy. The case indicates more the complexity of these secondary conditions than would be apparent from knowledge of postmortem findings only. Recovery from staphylococcemia is perhaps more frequent than thought; instances of it are described recently by Hug[27] and by Reymond and Alexandre.

RELATIONS OF STREPTOCOCCI TO SCARLET FEVER.

We come now to a brief discussion of the very important question of the exact relation of streptococci to scarlet fever. I have pointed out that some investigators impressed especially with the frequency, not to say constancy, of streptococcus infection of a general character in fatal forms of the disease, look on the streptococcus as playing a specific part in the scarlatinal process. The results of this study of the bacteriology of the blood of scarlatina in life, if they are to be given any value in deciding this question, would seem rather to favor the view that the streptococcus infection is secondary because absent in the large majority of the cases, even severe ones, and because though absent in the early part it may appear in the later stages of some cases. It seems to me that the theory that scarlatina is a streptococcus disease does not receive any direct support from these observations. In this connection it may be well to refer to the fact that streptococci seem to occupy about the same relations to diphtheria and to smallpox as they do to scarlet fever, if we judge from the frequency of streptococcus infections in these diseases. Dahmer[28] obtained streptococci from the heart's blood and spleen in 47 per cent. of 36 cases of fatal diphtheria, from the lungs in 85 per cent. and from the trachea in 100 per cent. As stated, Slawyk found streptococci in the blood in 22 and 20 per cent. of fatal cases of measles and diphtheria respectively. The literature on streptococcus infection in diphtheria is further reviewed by Councilman, Mallory and Pearce in their comprehensive study of this disease.[29] In Flexner's[30] statistics of terminal infections in chronic heart and kidney disease, the most prominent organism, in the local as well as the general infections, appears to be the streptococcus either singly or associated with the organisms.

James Ewing[31] found a streptococcus in the heart's blood of all of 29 cases of smallpox, the abundance being directly proportional to the severity of the disease. In five examinations during life all the cultures of the blood were sterile, but Arnaud[32] is quoted by Ewing as having found streptococci in the blood of two hemorrhagic cases during life. Ewing also found streptococci generally in the variolous skin lesions. This streptococcus, which does not seem to have any cultural or morphologic peculiarities, was pathogenic for mice and rabbits, but in no case did it produce any variolous lesions, while material from pustules caused smallpox in two monkeys. In hemorrhagic smallpox Ewing believes the condition to be one of symbiosis of the specific agent and the streptococcus. It would be interesting to know the results of the bacteriologic examination during life of a large series of cases of smallpox, which we see is a disease just as prominently associated with streptococci as is scarlet fever, but in which it is possible to show definitely that the real cause is distinct and peculiar.

In the face of these considerations it seems to me that the best hypothesis of the etiology of scarlet fever for working purposes is the one that in this disease two infections generally coexist in the oro-pharyngeal cavity. The cause of the specific, primary infection is unknown. So far its existence has not been rendered evident except by the specific contagious and clinico-epidemiologic peculiarities of scarlatina. The well-marked and durable active immunity, an immunity entirely different from anything we know of spontaneous or experimental streptococcus diseases may also be cited as strong evidence of a specific primary infection in scarlatina. The second infection is the streptococcus infection, which may be regarded as practically constant because there seems to be in all cases of scarlet fever a marked increase in the number of streptococci in the throat as compared with normal conditions, but this infection does not seem, as a rule, to be generalized when we except the severe, fatal cases. Whether the virus of scarlet fever directly increases the virulence of existing streptococci, stimulating them to the production of toxins peculiar to scarlet fever, and whether it favors general streptococcus infection by decreasing local or general resistance to streptococci, whatever the factors concerned may be, are questions on which further light is greatly needed.

Welch's Theory of Bacteriogenic Cytotoxins.—The view has also been advanced that scarlet fever is in one way a local disease and caused by *Streptococcus longus*, which, localizing in the pharynx, produces an erythemogenic toxin (Berge[33]). Much discussion has been carried on as to the specificity of the scarlatinal streptococci, but without final settlement of the question. It has been suggested that the cocci may be ordinary, well-known streptococci that under special conditions from a limited pharyngeal focus produce a specific toxin which, carried in the circulation, calls forth the cutaneous eruption. This view recalls the interesting theory recently advanced by Welch[34] in order to explain some of the effects of pathogenic organisms on the cells of the host not readily explainable by what can be learned from the study of bacterial cultures and the toxic substances there produced. This is the theory of the production of bacteriogenic cytotoxins under the influence of stimuli from the host according to the general principles of Ehrlich's

great theory of the production of toxins and lysins in general. In response to the action of atom complexes from the cells and fluids of the host the bacteria produce substances with special affinities that act as intermediary bodies in linking to cells of the host toxic complements derived either from the fluids of the host or from outside sources. It is, of course, conceivable that streptococci under special conditions might cause the symptoms and signs of scarlet fever, according to the principles of Welch's hypothesis of bacteriogenic toxins of somatogenic origin. This view of the nature of scarlet fever as yet lacks experimental proof. It receives neither support nor discredit from the results of this study.

CONCLUSIONS.

The conclusions that suggest themselves from this work so far as scarlatinal streptococcemia is concerned are that streptococci occasionally may be found in the blood of cases of scarlet fever that run a short, mild, and uncomplicated clinical course; that streptococci occur with relatively greater frequency in the more severe and protracted cases of scarlet fever in which there also may develop local complications and clinical signs of general infection, such as joint inflammations, but even in the grave cases of this kind spontaneous recovery may take place; and finally, that streptococcemia may not be demonstrable in fatal cases of scarlet fever. The theory that scarlet fever is a streptococcus disease does not seem to receive any direct support from this work.

The metric system is objected to by some London physicians on account of the liability of mistaking the abbreviation of "gram" for that of "grain." This difficulty is easily overcome by following the practice in the United States of designating "gram" by the abbreviation capital "Gr.," or "Gm.," and continuing to designate "grain" with small "gr." What is more, a prescription written in the metric system is very likely to have other terms than that of "gram," and no pharmacist would expect to receive a prescription with some terms in the metric system and others in the old, cumbersome system.—*Meyer Bros. Druggist.*

THE GLYCOSURIC SYMPTOM OF DISEASE AND ITS MEDICINAL TREATMENT.*

HEINRICH STERN, PH.D., M.D.
NEW YORK CITY.

An unusual amount of grape sugar in the urine is by no means an absolute indication of the presence of diabetes mellitus; it may be concomitant with, or sequential to, various other transitory, as well as chronic, anomalies. Thus glycosuria in its alimentary form *e saccharo* may be induced in the presence of various traumatic and non-traumatic neuroses; of alcoholism; of Graves' disease; of gastrointestinal disorders, as hyperacidity; of hepatic affections, etc.

Glycosuria, mostly of the spontaneous transitory type, may appear after injury and extirpation of less important organs; after ether and chloroform anesthesia; after administration of drugs and chemicals like phloridzin, mercuric bichlorid, chloral, morphin, strychnin, amyl nitrite, curare, thyroid preparations, adrenalin, etc.; after inhalation of carbon monoxid; after the excessive use of tobacco; during the luetic process, and during or after infectious diseases.

Generally speaking, non-diabetic glycosurias are the result of intoxications, that is, of slight or graver disturbances due either to influences coming from without or to such arising from within. Some transitory glycosurias may attain a certain degree of chronicity by the persistence of their underlying cause. These factors, however, are mostly of a non-permanent nature. While thus non-diabetic glycosuria may occasionally continue for protracted periods, diabetic glycosuria, or what is considered such, the concomitant phenomenon of exceedingly chronic processes is chronic in the majority of instances.

The vast difference between non-diabetic and diabetic glycosuria is the endurance of the causative factors in the latter. True diabetes exists before excretion of sugar supervenes,[1] and apart from some very rare exception, it still continues when, for the time being, glycosuria has ceased.

While we are able to assign or to trace the majority of non-diabetic glycosurias to a direct or more remote factor, we have as yet not succeeded in determining the substratum of diabetes proper. While, therefore, non-diabetic glycosurias may be amenable to rational treatment by influencing or removing their causal conditions, the therapy of true diabetes, on account of our meager knowledge concerning its pathology, must of necessity be of a more or less empiric nature.

Hence it occurs that the diet plays such an important rôle in the treatment of diabetes mellitus. Total or partial withdrawal of carbohydrates from the nutriment results in decrease or complete cessation of glycosuria and in obliteration of the other characteristic phenomena in almost every instance. Again, the exclusion of starchy and saccharous material from the food remains not without influence on non-diabetic glycosuria. Under an antidiabetic regimen non-diabetic melituria is frequently diminished, but although the latter hardly ever attains that degree of intensity which is common in diabetic glycosuria, yet it does not yield to carbohydrate-free nutriment in the same measure as diabetic glycosuria.

Those cases of long-continued glycosuria which are not modified by a diet devoid of farinaceous material, as

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

a general rule, are non-diabetic. This is especially the case (excepting, of course, when the patient is in the last stage of diabetes) when progressive bodily decline ensues after persistent adherence to a rigid antidiabetic dietary.

Furthermore, there are some instances in which diabetic glycosuria occurs contemporaneously with chronic non-diabetic mellituria in one and the same individual. Here the diabetic glycosuria and the other diabetic phenomena may subside on dieting; the glycosuria of non-diabetic origin, however, is likely to continue.

The good results attained by instituting a rigid diet in diabetes and its concomitant glycosuria lead to the supposition that analogue improvement would accrue from it in other glycosurias. In fact, little discrimination is exercised between the various types of glycosuria; one is, as a rule, treated like the other, that is, by an antidiabetic regimen.

Apart from exerting little or no influence on the respective foundation of the various non-diabetic melliturias, it is evident that the indiscriminate adaption of this excellent empiric method in combating the diabetic state to the treatment of all glycosurias irrespective of their underlying cause, is irrational and undoubtedly injurious in many instances.

If we bring to our mind that glycosuria is but a consequence, but an enunciation of manifold causes, we will understand that it is useless to treat the symptom *per se* and that we must try to influence the causal conditions directly.

Moreover, is it necessary to combat glycosuria whenever it occurs? My experience prompts me to say "No." If the patient feels well and if there is no evidence of physical or mental decline, I think we should not attempt to interfere with an eventual slight glycosuria. The end may not justify the means, especially if routine treatment implying deprivation is to be employed.

On account of the general application of the dietary methods to the management of the various glycosuric states and on account of injudicious prescribing and the polypharmacy of former years, medicinal treatment has of late been relegated to the rear. In the degree however, in which the influence of diet on amelioration of all the forms of mellituria has been overestimated, the potency of a number of medicinal agents on the various substrata of the glycosuric symptom is nowadays unquestionably underrated.

When both dietary and medicinal treatment are instituted contemporaneously, the real value of either of them can not be determined, because an eventual amelioration of the glycosuric symptom may be due to the diet alone, to the medicament alone, or to their combined influence.

INDICATIONS FOR THE INSTITUTION OF DIETARY TREATMENT ALONE.

All patients exhibiting the usual syndrome of diabetes mellitus, whose urine is free from acetone, diacetic and beta-oxybutyric acids, should be subjected to strict dietary regulations until all the symptoms have completely subsided, or until all symptoms excepting glycosuria, which in the meantime has declined to less than 1 per cent., have disappeared.

INDICATIONS FOR THE INSTITUTION OF MEDICINAL TREATMENT ALONE.

1. All cases systemically declining on the regulation of diet.

2. All cases in which a long-continued rigid diet can not effect complete cessation of the glycosuric symptom.

3. All cases excreting less than 1 per cent. of glucose in which the patient suffers from some disorder but does not exhibit the usual symptom-complex of diabetes mellitus.

4. Such cases in which diet has brought about subsidence of diabetic phenomena, but in which continued mental excitement is liable to effect recurrence of glycosuria.

INDICATIONS FOR BOTH DIETARY AND MEDICINAL TREATMENT.

1. All cases in which a dietary as well as a specific hygienic treatment is indicated and in which the patient through circumstances is prevented from properly executing them.

2. All cases exhibiting the syndrome of diabetes mellitus, but which for reasons of an accompanying affection, like chronic nephritis, for instance, can not be kept under a rigid antidiabetic regimen.

The following lines are devoted to the consideration of such drugs and chemicals which I have employed for the purpose of obliterating certain disorders and anomalies and the glycosurias accompanying them. Being entirely based on personal experience, it is obvious that account can be furnished of but a limited number of medicinal agents and their respective modes of employment.

Medicines do not seem to exert any influence in arresting the progressive tendency of diabetic deterioration, that morbid state characterized by apparent disintegration of body albumin into carbamid and dextrose. The medicinal treatment of this affection, with its unknown, or at least very obscure pathology, of course, was not considered at all. The medicinal treatment of chronic glycosurias of supposedly known origin, however, is dwelt on in the following.

PSEUDO-REMEDIES.

In the treatment of the glycosuric symptom we have to distinguish between two kinds of drugs and chemicals, viz., those which act as genuine remedies and those which interfere with various tests for urinary glucose, thereby misleading us to assume a lesser degree or the absence of glycosuria. Among the pseudo-remedies there are a number of so-called intestinal antiseptics which interfere more or less with the various testing methods, especially with the fermentation test. Jolles[2] pointed out that the guaiacol compound, known as benzosol, introduced into the organism yields levorotatory substances which would on that account indicate an apparent decrease of dextrose if the urine were examined polariscopically.

Record of Mrs. C. L., aged 59 years.

Date.	24 hrs. Urine. cc.	Medicine.	Dose.	Glucose. Fermentation. p. c.	Fermentation. grms.	Fehling. p. c.	Fehling. grms.

During the last year I have made a series of observations in glycosurias regarding the influence of certain

remedies on the urinary fermentative qualities. These observations are not as yet concluded, but to give an idea of the potent influence of some medicines in preventing complete fermentation, I cite from my notes the following instance:

Among the chemicals interfering with the reduction of the copper and bismuth solutions, thereby deceiving the observer as to the true state of affairs, is benzoylsulphonic imide the saccharin of commerce.

MEDICINAL AGENTS IN GLYCOSURIA DEPENDING ON PERVERTED FUNCTION OR REMOVAL OF GLANDS AND ORGANS.

(*a*) *Pancreas.*—As a general rule, pancreatic glycosuria is very little influenced by medicines. An alkaline treatment may avert its rapid progression, but it exerts no action on the existing phenomena. The ingestion of large amounts of alkaline waters, of course, diminishes the percentage of glucose by diluting the urine; the absolute amount of excreted glucose, however, remains thereby unaltered. Preparations of pancreas avail nothing beyond improving proteid-fat assimilation; they may thus prevent further systemic retrogression or may even effect augmentation of body weight. In a case of undoubted pancreatic diabetes with which was associated far-advanced chronic diffuse nephritis and achylia gastrica, I finally succeeded in reducing the glucose output which originally amounted to over 100 grams per diem, to 10 or 15 grams a day with the aid of this combination:

℞.	Pancreatin .....gr. xxx	2
	Trypsin	
	Foliæ myrtilli pulv., āā.....gr. xv	1
M.	Ft. pulv. d. tal. dos. L. (50).	
Sig.:	One powder three times a day.	

As the patient was under an exclusive milk regimen there is no doubt that it was the medication which effected the glucose reduction. The subsidence of the nephritis as well as of the diabetic phenomena went hand in hand with the decline of the glycosuria. The case was under my observation about two years ago, and appeared then rather hopeless. Lately I heard that the patient is well enough to attend to his business.

The trypsin was added to the pancreatin after this *per se* had been prescribed and had been found wanting. It was my intention to add each of the three pancreatic ferments to the pancreatin—separately, of course. This was done to increase the action of the pancreatin and to find out whether any of the pancreatic ferments occurred in diminished amounts in the organism to the deficiency of which the glycosuria could have been due.

The same combination worked satisfactorily, at least for some time, in some other instances of apparent pancreatogenous glycosuria. In two or three similar instances, however, it displayed no activity whatsoever.

(*b*) *Liver.*—Common or hepatogenous glycosuria, that form which is due to interference with the glycogenic function of the liver to the extent that the ingested carbohydrates are not utilized normally,[3] is best managed by dietary means. In exceptional cases only, as in the presence of acetonemia and acidosis, or where on account of an associated affection a strict antidiabetic regimen can not be continued for any length of time, is medication called for. It is here that the various alkalies and the prolonged administration of arsenical preparations do most good.

Chionanthus virginica has given me good results in some glycosurias which were dependent on functional liver disease.

In acid intoxication the following combination has given me very gratifying results:

℞.	Sodii bicarbonici		
	Calcii carbonici prec., āā.....ʒiss	45	
	Sodii pyrophosphorici .....ʒiiss	10	
M.			

From 10 to 50 grams of this combination should be taken every day in plain or carbonated water for a protracted period.

When coma seems imminent, and during the comatose state, from 2 to 6 grams of precipitated calcium carbonate, suspended in water by the addition of 25 per cent. its weight of acacia, and administered every 2, 3 or 4 hours of enteroclysis, has proved very useful in my hands.[4]

Mineral waters deserve some recognition in the therapeutics of hepatogenous glycosuria. The action of the salt solutions, however, contrary to former belief, is not a direct one. By increasing cellular metabolism they stimulate hepatic activity, and hence there may be a greater tolerance for carbohydrates.

As a general rule, the glycosuria yields in the same ratio as the underlying affection disperses.

(*c*) *Gastrointestinal Tract.*—Chronic affections of the stomach and intestines stand occasionally at the foundation of enduring glycosuria. I had a case under observation in which long-continued hyperchlorhydria proved to be the cause of the obstinate glycosuria, as by suppression of the former the latter became also obliterated.

If an individual has glycosuria and at the same time a chronic gastric or intestinal disorder, the latter should be treated first, especially when other diabetic phenomena are missing and when the excreted dextrose amounts to less than 1 per cent. Of course, such dietary treatment has to be pursued, as the particular gastric or intestinal affection demands. I think milk is best adapted for most cases, at least at the outset. If, in addition to the proper diet the same medication were employed as would be if glycosuria were not present, there is little doubt that with the amelioration of the underlying affection the glycosuria would also cease.

Antacids, antifermentatives, stomachics, etc., and stomach or rectal tubes should be utilized in much the same manner as if the glycosuric condition did not exist.

(*d*) *Kidneys.*—Phloridzin glycosuria, the association of chronic diffuse nephritis with glycosuria when the former is antedating the latter, and the frequent excretion of glucose in renal hemorrhages seems to point to an eventual renal origin of glycosuria.

I have seen four cases in which glycosuria followed pre-existing Bright's disease. Dietary regulations adapted to the condition of the kidneys—milk predominating—and medication directed toward amelioration of the nephritic state, brought about decided general improvement in two cases. In the one case, urinary glucose, after three weeks' treatment, was reduced from 0.47 to 0.14 per cent., and in the other, glucose was not excreted any more in appreciable amounts in the second week following the institution of treatment.

(*e*) *Other Organs.*—As long as the functions of a diseased or extirpated organ are assumed by another organ, in other words, as long as the metabolic equilibrium remains undisturbed, glycosuria will not occur. It is therefore often necessary to treat, that is, to stimulate, the organs which are expected to exert vicarious functions.

In a case under my observation glycosuria occurred after ulceration and subsequent removal of both sub-

lingual glands. A diet somewhat reduced in starchy material, an occasional mild ptyalagogue and the administration of ptyalin, or pancreatin, kept the glycosuria in check for over two years. Later true diabetes supervened, for the treatment of which a rigid antidiabetic diet had to be resorted to.

Hyperthyroidism is occasionally associated with glycosuria. In the two cases of the association which came under my observation thyroid therapy, arsenic, etc., were of no avail.[5]

MEDICINAL AGENTS IN GLYCOSURIA DEPENDING ON URIC-ACIDEMIA AND POLYSARCIA.

Glycosuria arises not infrequently from a gouty basis. This is readily understood when we remember that both may be the result of similar intracellular processes. The medicinal treatment should be chosen to influence the substratum common to both affections. In such instances diabetic phenomena, excepting glycosuria, if present at all, are only slightly pronounced. The glycosuria hardly ever exceeds 1 per cent.; the urine is normal, or almost normal, in amount; its density is high.

As a rigid antidiabetic diet is here contraindicated on account of the mild form of the secondary affection and of the untoward influence it may exert on the gouty state, medicaments should be the factors mostly to be dependent on in the therapy of the two concurring conditions.

Antilithiatic measures causing amelioration of the gouty affection subdue also the accompanying glycosuria in the majority of instances. In those cases in which glycosuria persists after cessation of the gouty phenomena, glycosuria is very likely the original abnormal condition and is depending on some other cause.

Medicines like the salicylates, salol, piperazin, tincture and salts of iodin, aspirin, various alkalies, alkalin-muriatic waters, and, in a sense, also opium, formerly lauded as efficacious in the treatment of glycosuria and diabetes, probably possess remedial qualities only when the glycosuric condition is the consequence of a gouty process.

When obesity preceded glycosuria, a diet effecting reduction of body weight is imperative. Diet as well as exercise should be carefully regulated according to the type of obesity.[6] Thyroid therapy, on account of its well-known tendency to produce or to intensify glycosuria, should be resorted to only under extreme circumstances. Fucus vesiculosis, especially the citric acid extract as devised by me, I have found of great value in the reduction of polysarcia and its accompanying glycosuria.

MEDICINAL AGENTS IN GLYCOSURIA DEPENDING ON LUETIC CONDITIONS.

Syphilitic infection seems to be much oftener the direct cause of glycosuria than is generally assumed. We have syphilitic affections of the liver, of the gastrointestinal tract, of the pancreas and especially of the brain. Glycosuria may be attendant on an eventual syphilitic process in any of these organs. I have seen two cases during the last year, both young men who were rejected by two of the large life insurance companies on account of "diabetes." In Case 1 the excreted glucose never amounted to more than 0.25 per cent., or about 3.5 grams per diem; in Case 2 from 5 to 6 grams of glucose were egested daily. Both patients admitted to have been infected with syphilis. Antiluetic treatment resulted in the cessation of glycosuria in Case 2; Case 1 is still under observation as the glycosuria persists. Case 2 was granted a life insurance policy some time ago.

Potassium iodid and the mercurials are the indicated remedies. Mercury should be applied by inunctions or by subcutaneous injections. I have seen speedy results following the hypodermatic injection of mercuric bichlorid. This, by the way, is the only rational manner in which to administer corrosive sublimate. Introduced into the stomach it is frequently followed by untoward secondary effects, and it does not display that degree of activity which it exhibits when injected hypodermatically. I use solutions of the strength of 1, 2 and 3 per cent., to each of which 2 per cent. sodium chlorid is added. I generally start with 8 drops of the 1 per cent. solution, adding two drops at each subsequent injection. When 15 or 20 drops have been used—the capacity of the ordinary hypodermic syringe—I continue with 8 or 9 drops of the 2 per cent. solution, adding but one drop at each subsequent injection. If, after prolonged administration of 15 or 20 drops of the 2 per cent. solution, the syphilitic process is not under control, the 3 per cent. solution should be utilized. In the first two weeks injections are daily made; later on they are administered at first every second day and then twice a week. I inject the solutions through a platinum iridium needle, which is introduced at least to the depth of three centimeters in order to prevent abscess formation. The injections are best made into the buttocks.

MEDICINAL AGENTS IN NEUROGENOUS GLYCOSURIA.

Chronic glycosuria is very frequently the enunciation of an affection of the nervous system. It has been found to occur in tumors of the brain, particularly when located in the medulla oblongata, cerebellum or pons varolii; in dementia paralytica; in multiple sclerosis; in cerebrospinal meningitis; in cerebral hemorrhage; in encephalomalacia; in tabes; in affections of the sympathetic nervous system; in traumatic conditions of the brain; in traumatic and functional neuroses, etc.

Generally speaking, the neurogenous type of glycosuria is the one in which medicinal treatment seems *a priori* indicated. The majority of medicaments propounded for the "cure of diabetes" exert their action on and through the nervous system. Opium (morphin, codein, heroin, dionin), the bromids, chloral hydrate, chloralamid, antipyrin, acetanilid, phenacetin, belladonna, strychnin, *Syzygium jambulanum*, ergot, uranium nitrate—these all influence the nervous system to a greater or less extent.

In certain instances of neurogenous glycosuria, especially in such cases where the output of glucose does not exceed 1 per cent., that is, about 15 grams per day, and where the patient is rather emaciated, well-directed medicinal treatment alone will often afford relief of the nervous affection as well as of its glycosuric phenomenon. In other cases, however, in which we have to deal with a well-nourished and even obese subject egesting more than 1 per cent. of grape sugar, a proper dietary treatment, at least at the outset, should go hand in hand with the administration of medicines.

As many of the nervous conditions underlying glycosuria are of an exceedingly chronic nature, the poisonous and narcotic remedies should be resorted to on exceptional occasions only. I do not think that I prescribed opium or its alkaloids or derivatives (for the condition *per se*) more than in 5 per cent. of the several hundred cases of chronic glycosuria which have come under my observation. I only give opium when excessive cellular catabolism is to be arrested, that is, in cases rapidly declining. Opium retards the intracellular processes, and on this account it may act efficaciously in the

specific instances, at least for the time being, however, in consequence thereof it is a double-edged sword which may also cut the other way.

If the effect of opium is desired, its alkaloids or derivatives should not be given. In the control of the glycosuric symptom opium seems to exhibit qualities not possessed by either of them. However, morphin is more reliable than codein, and this acts prompter than heroin or dionin.

The bromids, cerebral and spinal depressants as they are, may subdue some of the nervous symptoms, but I found them rather indifferent concerning suppression of the glycosuric phenomenon. Chloral hydrate, by reason of its antispasmodic and depressant properties, affords relief in certain conditions of the nervous system underlying glycosuria without influencing the latter.

Antipyrin is not without merit in reducing glycosuria consequential to functional neurosis, particularly if the latter is a sequela of an acute infectious disease. Glycosuria on the basis of a traumatic neurosis sometimes yields to belladonna or atropin. I have seen satisfactory results from the administration of small doses of ergot in glycosuria following injury of the nervous system. In no case of glycosuria in which uranium nitrate alone was employed did I notice any material change in the output of glucose.

Syzygium jambulanum is undoubtedly that agent which is of greater value in the suppression of neurogenous glycosuria than any other medicinal substance as yet advocated for that purpose. Preparations of this drug obtainable are powdered jambul seeds and fluid extract of jambul seed. The dose of either should be in the beginning 0.75 gram three times a day; this is to be increased to 10, 20 and even 30 grams a day.

I had a solid extract prepared from the jambul seeds which in appearance and consistency resembles the extract of aloes. I prescribe it in the form of pills or capsules. I have given as much as 10 grams a day of this solid extract.

There seem to be different qualities of jambul seed in the market. I judge so from the degree of activity displayed by various specimens. When, therefore, the administration of jambul has proved a failure in lowering the glucose output, it is best to obtain the drug from some other source and to try it again.

Jambul in small doses may be given for protracted periods. It is best to continue its administration indefinitely in all those conditions where the nervous affection proves to be unyielding and where the accompanying glycosuria is generally of a low degree, but tending to occasional exacerbations. The following mass may be put up in pills or gelatin capsules. In cases where the combination was indicated it has nearly always kept the glycosuria at a minimum point:

℞.	Ext. seminis jambulæ	3ixss	37 | 5
	Ext. valerianæ	gr. cxiiss	7 | 5
	Ext. fuci vesiculosis	gr. lxxv	5
	Ext. cypripedii		
	Ext. scutellariæ, āā	gr. xxxviiss	2 | 5
	Ext. piscidiæ erythrin	gr. xx	1 | 25
	Ext. gelsemii		
	Ext. belladonnæ, āā	gr. viiss	0 | 5
	Ext. physostigmæ	gr. iv	0 | 25
	Aloin	gr. xv	1

DISCUSSION.

Dr. W. W. Tompkins, Charlestown, W. Va.—In the region in which I live the population is about one-third negroes. They are largely syphilitic and tuberculous, but it is remarkable that I have never seen a case of diabetes or glycosuria in the colored race. Other practitioners in my neighborhod, on being asked, could not recall having seen a case. I can not offer any reason for the immunity, if it exists; they live in about the same way and eat the same food that the whites do. They eat sugar and are very fond of sweets, but do not seem to have glycosuria as the whites do. Has the author made any observations on this point? I do not just comprehend the difference that Dr. Stern made between glycosuria and diabetes and wish for a clearer definition.

Dr. H. C. Wood, Jr., Philadelphia—I have given methylene blue to three cases of diabetes mellitus, with apparently good results in two. One case improved very distinctly; this case happened to be in a negro. On one point I desire some light: Does the form in which the carbohydrates are administered in these patients make any difference? In the German medical journals lately much has been said about the value of potatoes in the dietary of diabetics. I can not understand the rationale of giving potatoes and excluding bread; or why potatoes should be good and bread bad for a patient with diabetes.

Dr. Henry R. Slack, La Grange, Ga.—In regard to the use of potatoes as a substitute for other forms of starchy food in diabetes, I have closely watched several cases while under this treatment in the Johns Hopkins Hospital at Baltimore. A number of experiments were made with regard to the effects of different articles of diet on the excretion of sugar. In one case, a divinity student, after taking 500 gm. of bread, 390 gm. of grape sugar were excreted; while after taking 800 gm. of potatoes he only had 90 gm. of sugar in his urine. In another case, that of a young woman, while the results were not so marked as in the former, yet the decline in the glucose was notable. On 400 gm. bread she excreted nearly 300 gm. sugar, while on 600 gm. potato it was less than 100 daily. One day I was much surprised, while the patient was on the potato diet, to find that the amount of sugar suddenly went way up, to over 200 gm.; but I discovered afterward that visitors had been with the patient the day before, and that they had given her about a quarter of a pound of candy to eat, which fully explained it. However, in a few days, with care in the diet, the amount of sugar again diminished. It showed that while the girl had only eaten about 60 gm. of candy still the candy had so stimulated the glycosuria that not only the candy was added to the sugar but more of the starch of the potato had also been converted. I offer no explanations for this phenomenon, but merely state it as a clinical observation that less sugar is excreted when the patient is kept on potatoes than when on any other form of starchy food.

Dr. W. J. Robinson, New York City—There are many diseases about which we really know very little; but about diabetes and rheumatism we know less than of any other. We know absolutely nothing about the etiology of either disease. With regard to the use of potatoes in the diet: A few years ago if a physician had dared to propose the use of potatoes it would have been taken as an indication of gross ignorance; but now this is advocated by some of the best practitioners. It has been suggested in explanation that the potato contains a large amount of potassium salts, and that the condition giving rise to the diabetes is favorably affected by these salts in the potato, when used as food. It is also claimed that the carbohydrates of the potato act more favorably than other starches. If this is so it will explain the reduction in the grape-sugar of the urine when potatoes are used. Whether true or not, if the result of eating potatoes is a reduction of the glycosuria, we

can give them empirically, just as we use certain drugs in the treatment of diabetes, on a purely empirical basis.

Dr. A. B. Lyons, Detroit—Not long ago my attention was directed to one of the many preparations recommended to physicians for the treatment of diabetes, which was said to be made from one of the myrtaceæ. The formula given called for "myrtle (crystals)." This puzzled me at first, but on examining the preparation I arrived at an interpretation. Myrtle crystals can mean nothing but jambul seeds, a well-known remedy in some forms of glycosuria.

Dr. W. J. Robinson, New York City—A few years ago a remedy for diabetes was brought out and was much vaunted in Germany by the manufacturers as an infallible specific. It was called "musol." It was found afterward that it was absolutely nothing but salol.

Dr. Heinrich Stern, New York City—Some of the participants in the discussion must have misunderstood me as I did not utter a single word as to the medicinal treatment of diabetes mellitus. I merely considered the glycosuric symptom of disease and the medicinal treatment of conditions attended by this symptom, and more especially of certain types of disease in which glycosuria is apt to occur. I can not accept the statement that we know nothing about the cause of this symptom. It is the office of the physician to investigate the etiologic factors of each individual case presenting itself for treatment. Routine treatment in glycosuric conditions is certainly unscientific and often injurious. To treat every case of glycosuria like diabetes is a very easy thing, but it is not the proper procedure. In a large proportion of cases of non-diabetic glycosuria, perhaps in over 90 per cent. the causes of the glycosuric symptom can be ascertained and with the knowledge of the cause to guide us, it may be successfully treated. While we know very little as to the causative factors of diabetes itself, we know a good deal about the various types of glycosuria and the conditions underlying the appearance of the glycosuric phenomenon. In reply to the question as to the frequency of diabetes in negroes, some years ago I studied and arranged the records relating to vital statistics in the city of New York, and found that in a period of eleven years prior to 1900 there had been reported fifteen cases of diabetes that had ended fatally in negroes. One of the cases of Graves' disease, accompanied by glycosuria, which I reported before the Section on Practice of Medicine, occurred in a negress. So that, while it is unusual to find grave conditions attended by glycosuria in the negro, such cases are occasionally observed.

Among the remedies considered in my communication I only included such as I have personally found to be efficacious in the treatment of the glycosuric symptom. I purposely omitted all those so-called remedies which, after continued and repeated trials, I have found valueless in ameliorating the output of urinary glucose. In answer to Dr. Wood's question, I have no definite results to report from the use of methylene-blue. I have used the chemical not very frequently and only reluctantly. Still, in those cases in which I have employed it, it was continued for protracted periods and the cases were kept under close observation. Ergot has rendered me good service in a number of instances. Its action is especially marked in cases characterized by pronounced polyuria. It influences the circulation of the brain and hence is indicated when the cause of the glycosuria is within the brain and when it seems necessary to produce an artificial anemia there. It is also of decided influence in cases depending on or concurring with cardiac hypertrophy.

Now as regards the form of carbohydrates to be allowed in the diet. I did not speak on the dietary treatment of either diabetes or glycosuria. This is a chapter of itself, and a very long chapter at that. I pointed out that dietetic treatment is not always indicated in the various non-diabetic glycosurias. The question of carbohydrates, therefore, could only be of importance in non-diabetic glycosurias, if the patient was also affected with a gastric disturbance demanding for a time the exclusion of starchy or saccharin material. The question was raised as to the tolerance of potatoes by the diabetic organism. A French clinician was the one who first introduced the potato diet. I have allowed the use of potatoes in a number of patients. Certain patients, it is true, tolerated the potatoes very well, but it must not be forgotten that at least the same proportion of diabetic persons tolerate other forms of starchy food if taken in moderation and that there exists a great number of diabetics who can partake of large quantities of milk with impunity. I do not consider the potassium salts contained in the potatoes to be of any advantage, for if they were, potassium as such or any of its salts should have proved of benefit in the treatment of the diabetic or glycosuric conditions. This is plainly not the case. In comparing potatoes with other forms of carbohydrate food, it should be remembered that, in the first place, potatoes contain very small amounts of solid material, therefore also of starch, in proportion to their bulk. This is one reason why their employment may be less objectionable than that of bread. They are bulky; in one hundred grams of potatoes but twenty-one grams of carbohydrate matter are contained, while in the same amount of wheaten or rye flour from 60 to 90 grams of carbohydrates are found. To obtain the same caloric value about four times as much of potatoes as of flour or bread must be consumed. The potato diet may satisfy a patient, but he has taken very little starch and a great deal of water. In the way of substitutes for bread I have advised the preparation of peanut flour and bread and cakes baked therefrom. As a general rule, however, I find that most patients get along with little or no bread.

I am no advocate of bread substitutes; the dietetic treatment is essential in diabetes. Combined with a medicinal treatment, dietary regulations may be very beneficial in the various forms of glycosuria, but a majority of instances of glycosuria do not ask for an antidiabetic regimen.

SOME RARE FORMS OF CHRONIC PERITONITIS

ASSOCIATED WITH PRODUCTIVE FIBROSIS AND HYALINE DEGENERATION.*

ALBERT G. NICHOLLS, M.A., M.D.
Lecturer in Pathology, McGill University, and Assistant Pathologist to the Royal Victoria Hospital.
MONTREAL.

In the discussion of the subject of peritonitis an element of confusion has been introduced owing to the loose way in which certain descriptive terms have been used. A confusion in the nomenclature leads inevitably to a confusion of ideas. We find that many writers of repute use terms such as "peritonitis," "perihepatitis" and "perisplenitis" to designate a condition in which fibrous bands of adhesion connect the various viscera or traverse serous cavities, even in the absence of any sign of accompanying active inflammation. While, of course, such adhesions are an evidence of an inflammatory process, they are the result of such a process rather than the process itself. Now a result can not be the cause; scar-tissue is not the wound, nor are fibrous adhesions inflammation. It is obviously then incorrect and misleading to use a term like peritonitis to designate such a condition. We should prefer to restrict the term to those cases in which inflammation is actually in progress at the time of observation, since fibrous adhesions may be merely evidence of an inflammatory process long since past and gone. There are cases, however, where adhesions occur with the addition of changes due to an associated active process, with certain forms of which I propose to deal.

In the course of the present communication I desire more especially to call attention to a peculiar form of chronic peritonitis of progressive development, several instances of which have come under my notice recently

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. A. Stengel, W. S. Hall and L. Hektoen.

that is of considerable interest and importance. While from the point of view of etiology several varieties must be recognized, anatomically speaking they have much in common; in many there is more or less exudation of a sero-fibrinous or fibrino-purulent character, while adhesions, plastic and fibrous, are common. The feature, however, that gives the affection its characteristic form is a peculiar overgrowth of fibrous tissue on the peritoneal membrane and the surfaces of the abdominal viscera leading to induration and deformity. This fibrous tissue undergoes hyaline transformation so that plaques or continuous sheets of pearly-white cartilaginous appearance are produced in various parts. The material in question has every feature of newly-formed tissue, and the disease is both chronic and progressive. Shrinkage of the fibrous tissue takes place, hence one might correctly speak of the disease as a chronic "indurative" peritonitis.

The process when diffuse is usually most marked about the upper part of the peritoneal cavity, the capsules of the liver and spleen, the mesentery and the great omentum, and may even extend to the pleural and pericardial cavities. Although not new, the subject is one that has attracted but little attention in proportion to its importance. Cases of this kind usually come under the notice of the clinician with ascites, slight abdominal pain, alteration in the size of the liver and slight anasarca, so that at first sight there is a considerable resemblance to cirrhosis of the liver. These cases are so remarkable and differ so much from the ordinary chronic peritonitis that their exact relationship is not at first sight apprehended.

A brief reference, in passing, to the forms of peritonitis may not be out of place at this point, since it will render plainer what is to come. All peritonitides may be divided into primary and secondary forms. A primary peritonitis is defined by Flexner[1] to be "a condition in which the inflammation, usually diffuse, of the serous cavity takes place without the mediation of any of its contained organs, and independently of any surgical operation on its parts." As Flexner correctly points out, these are usually due to terminal infection. From their nature it is obvious that they can not lead to the chronic disease and so may be dismissed at once from our consideration. Chronic peritonitis may be developed from an originally acute disease, either by a succession of relapses or a gradual amelioration in the severity of the attack, or it may develop insidiously from the first. A point of some importance in chronic peritonitis, even if it subsequently become generalized, is that, with the exception of those cases dependent on ascites or secondary infection, it is practically always local at the beginning and is in almost every case secondary to disease of one of the abdominal viscera. Careful examination in these cases will show that the vast majority of instances arise by the extension of disease from some organ in close anatomic relation to the peritoneal membrane. The ways in which this may occur are multitudinous, but the more important may be mentioned—gastric or intestinal ulcers, cholecystitis, pericholecystitis, traumatism, abscess or gumma of the liver, inflammations of the internal female genitalia, hernia, tuberculosis and carcinoma, echinococcus cysts.

THE VARIETIES OF PERITONITIS.

In many cases it is not uncommon to find local inflammation with adhesion of the adjacent surfaces, but a certain percentage of these will go on to a wide dissemination; we have, therefore, to recognize both local and diffuse forms. Why a local process of this nature should persistently spread is not very clear. The answer is perhaps to be found in the nature of the initial lesion which is usually of a type not amenable to ordinary medicinal measures, while it usually occurs in some part where there is continuous mechanical irritation incident to the functioning of the parts affected. Probably, too, the germs at work are of relatively low virulence and adhesions form which tend to inhibit the activity of the process, and thus convert what would otherwise be an acute process into a slowly progressive one. Dissemination of the infective agent takes place through the lymph system rather than by direct extension over the peritoneal surface. According to the nature of the exudation produced we can conveniently divide chronic peritonitis (diffuse) into three main forms:

1. *Chronic Exudative Peritonitis,* in which there is a considerable outpouring of serous, sero-fibrinous or fibrino-purulent fluid, with loose plastic adhesions; fibrous bands are few or absent.

2. *Chronic Exudative and Adhesive Peritonitis,* presenting less exudation, but with somewhat numerous and firm adhesions, often leading to sacculation of the contents.

3. *Chronic Hyperplastic Peritonitis,* in which there is sero-fibrinous or fibrino-purulent exudation, but more or less generalized adhesions are the rule, together with the formation of firm nodules or continuous sheets of hyaline fibrous tissue.

Many points of interest tempt us to discussion, but in the present paper we are principally concerned with the third form:

CHRONIC HYPERPLASTIC PERITONITIS.

In entering on a consideration of this affection it may be said at the outset that this form is much rarer than either of the other two. Many cases are merely of pathologic interest, since they are only discovered incidentally at autopsy, but some few, owing to the extent of the lesions and their localization to special organs, are susceptible of diagnosis during life, and hence are of clinical importance. Anatomically speaking, the cardinal features of the disease are the production of more or less exudation into the abdominal cavity and the production of fibrosis leading to the formation of sporadic elevated nodules on the peritoneal surface or to a continuous fibrous membrane of considerable thickness and cartilaginous texture on the various viscera.

Judging from a careful review of the literature, cases of this kind are not very common, but this, I think, is possibly due to the fact that attention has not been sufficiently drawn to the possibility of their occurrence. As an illustration of the early stage in the process I may refer briefly to the following case coming under my own notice at the Royal Victoria Hospital:

Case 1.—Male, aged 80, gave a history of intestinal disturbance in the epigastrium, pain after eating, epigastric tenderness, occasional vomiting and progressive emaciation. When admitted to the wards free fluid was found in the abdominal cavity, with tenderness and resistance in the epigastrium, and to a less extent over the ileocecal region.

Autopsy.—The gall bladder contained calculi and was shrunken, with greatly thickened walls. On the under surface of the diaphragm were numerous pearly nodules of hyaline, translucent appearance, which microscopically were composed of laminated fibrous tissue with hyaline degeneration. The great omentum was converted into a fibrous cord, and the spleen was tied up in fibrous adhesions. Between the coils

of the intestines were numerous plastic and some firmer adhesions, with pockets of fibrino-purulent fluid. A glassy avascular membrane of new formation covered over the whole front of the abdominal cavity, through which the intestines could be indistinctly made out.

Here, no doubt, the exciting cause of the peritonitis was cholelithiasis with cholecystitis and pericholecystitis. A very similar case has been recorded by Hübler, Sr.,[2] in a woman of 56, who suffered from repeated attacks of biliary colic and jaundice followed by ascites. Death ensued after ten years, and at autopsy cholecystitis was found, the peritoneum over the anterior abdominal wall was thickened and the liver covered by a thick membrane of porcelain-like appearance; a local purulent peritonitis was also present. Here the lesion was more diffuse than in my own case, but in both we have a chronic diffuse peritonitis of the peculiar type in question, clearly originating in a local inflammatory lesion.

Some of these cases appear to be due to trauma, as in an instance related by Henoch,[3] where a little girl was kicked in the region of the liver and some weeks later developed enormous ascites. At autopsy an extensive hemorrhagic and hyperplastic peritonitis was discovered, together with bruising and laceration of the liver. Von Wuncheim[4] records a similar case apparently of a different origin, in a man of 43, who had suffered for four years with palpitation of the heart and ascites. At autopsy there was ascites and the peritoneum was greatly thickened and of pearly-white appearance. A large aortic aneurism had ruptured into the right auricle, and in addition to the chronic peritonitis there was contraction of the aortic valves, chronic Bright's disease and passive congestion of the organs. Von Wunscheim's case suggests strongly that the determining factor in the production of the peritonitis was the vascular disturbance and transudation induced by the heart lesion.

Both Rokitansky[5] and Ziegler[6] state that local thickenings of the peritoneum may arise from the irritation of a simple ascites. But after a careful investigation into this point I have not been able to satisfy myself that a diffuse thickening of the membrane of the type referred to occurs from this cause. It is well known how frequently an acute peritonitis complicates those diseases associated with ascites, such as cirrhosis of the liver and Bright's disease, but as yet it has not been made clear in how far this event is due to secondary infection rather than to the simple mechanical irritation of fluid. I am inclined to think myself that in every case infection is at work. It is probable, however, that passive congestion of the organ may lead to a local thickening of the peritoneum covering it. Taking the spleen, for instance, in 467 postmortems of which I have notes, fibro-hyaline plaques were found on the capsule 17 times, and the most important single causative factor was passive congestion. This view is also held by Eichhorst.[7] In my experience, however, in cases of passive congestion the hyaline thickening remains strictly local. So far as I can see from a careful study of this form of peritonitis the most important factor is the extension of an inflammatory process from some one of the contained viscera. I have been led to this conclusion from a consideration of the etiology, the clinical course of the disease and a careful study of the exudation and the thickened membrane produced.

In another class of cases the peritoneum is affected together with other serous membranes. In a recent study of this form,[8] for which I have proposed the term "Multiple Progressive Hyaloserositis," I have been able to collect 14 instances, and several more are now recorded. (See A. O. J. Kelly.[17]) As a rule the pericardium, the pleuræ and the upper part of the peritoneal membrane are the parts affected, although variations occur. About half the cases seem to have started from some lesion of the abdominal viscera, frequently a perihepatitis secondary to some inflammatory affection of the liver. One case apparently started from a duodenal ulcer. Next to this the most important association is a chronic indurative mediastino-pericarditis extending secondarily to the peritoneal cavity. More rarely still chronic pleurisy is an exciting cause. In such cases extension of the inflammatory agents takes place by means of the lymphatics of the various cavities which have free communication. The most important form of this type is chronic perihepatitis, to which Curschmann[9] has drawn attention under the name of "Zuckergussleber," or "icing liver." Chronic perihepatitis is almost invariably associated with chronic peritonitis,, although the converse proposition by no means holds good. Clinically, the most striking symptoms are, general weakness, shortness of breath and a gradual increasing and refractory ascites; jaundice is uncommon in uncomplicated cases. The resemblance to atrophic cirrhosis of the liver is striking, but differential diagnosis is possible. In the form beginning with peritonitis and perihepatitis the leading features are ascites, which tends to return after repeated paracentesis; the liver is at first enlarged and later small, smooth and hard. Later, pleural effusion or adhesions may form, particularly on the right side, and later still a similar involvement of the pericardium leading to cardiac insufficiency.

The disease may begin acutely with fever, rigors, pain in the epigastrium and tenderness in the hepatic region. Other cases develop insidiously and do not come under observation until the ascites is well marked. The spleen is usually enlarged. A case of this type is the following, which I have have had an opportunity of studying fully:

Case 2.—A woman, aged 48, had been ill for some two years with weakness, dyspnea, palpitation of the heart, and extreme anasarca.

Autopsy.—The abdomen contained 6000 c.cm. of straw-colored fluid clotting readily; there were fibrous adhesions between the great omentum and the uterus and left ovary, and between the coils of the intestines. The great omentum was contracted into a firm fibrous mass, the mesentery thickened and greatly shortened.

A striking feature was that in the upper part of the abdominal cavity, particularly the capsules of the liver and spleen, the serous membrane was greatly thickened and of pearly-white gelatinous appearance. Both pleural sacs were obliterated and the pleural membrane showed the same peculiar metamorphosis. The two layers of the pericardium were universally adherent by fibrous adhesions.

Microscopic Examination.—This showed that the material referred to was an organizing inflammatory deposit, the main features of which were hyperplasia of fibrous tissue with consecutive hyaline degeneration.

While, as has been mentioned, most of such cases hitherto reported have originated in the peritoneal cavity, in others the peritonitis arose by extension from the pericardium or pleuræ. In cases of hyperplastic peritonitis such as has just been described it is difficult, in the light of our present knowledge, to assign the exact cause. In most there is a history of acute infection of various kinds, such as acute hepatitis, cholecystitis and pericholecystitis, typhoid fever, perityphlitis and the like, and it is probable in these cases that we are dealing with an infection by micro-organisms of relatively low virulence, so that for a considerable length of time the

tissues of the body are able to resist the inroads of the disease, and thus the fatal termination is almost indefinitely prolonged.

Much interest attaches to the question: What part does tuberculosis play in this form of peritonitis? Louis[10] held that every case of chronic peritonitis was tubercular. But this is certainly incorrect. It is probably true that the majority of cases are tubercular, but numerous exceptions occur, as the above recorded cases sufficiently prove, for in none of them was the *Bacillus tuberculosis* discovered, although search was made for it. It is quite possible, however, for the tubercle bacillus to produce a hyaline and productive fibrosis of the peritoneal membrane, quite comparable to the simple form previously described. This fact has been but little recognized up to the present. Within recent years numerous observations have been made tending to show that tuberculosis of the serous membranes and of the various organs is not necessarily a destructive process, but is, on the contrary, occasionally a constructive one; caseation may be slight or absent while fibrous hyperplasia is in excess. Such hyperplastic tuberculosis, or "pseudo-neoplastic growth," has been met with in the larynx, where it has been mistaken for carcinoma.

Analogous to this is that peculiar form of lymphadenitis, which clinically may be taken for Hodgkin's disease, until the discovery of the specific bacillus reveals the true nature of the case. Why the disease should take this form is difficult to say, unless it be, as Lartigau has suggested, that we are dealing with a bacillus of very low virulence. It is possible, too, that bacilli from other than human sources may be at work. The following case will illustrate the hyperplastic type of tubercular peritonitis:

Case 3.—A male, aged 37; five months before coming under observation noticed that he was losing flesh and his appetite was failing. Two months before admission the abdomen was noted to be hard and somewhat distended; there was neither tenderness nor vomiting and the bowels were regular. Three days before admission he was seized with severe pain in the left hypochondriac region which gradually became generalized. On admission he was found to be greatly emaciated and cachectic with great abdominal distension and rigidity of the abdominal walls. A friction rub was detected over the left base anteriorly and there was slight cough; irregular areas of dulness were noted over the abdomen. The diagnosis was probably tubercular peritonitis with perforation and acute septic peritonitis.

Autopsy.—There was found sero-fibrinous pleurisy on the left side and scattered tubercles were present on the left pleura and diaphragm. A few older tubercles were found in the right lung and peribronchial glands. The main interest centered in the condition of the peritoneum. The abdominal cavity contained fecal material and gas due to perforation of the ileum; some chronic fibroid tuberculosis was found matting together the intestines. The liver capsule was greatly thickened, covered with shaggy adhesions and showed some hyaline degeneration; the liver was adherent to the diaphragm. The spleen was also adherent to the diaphragm and its capsule showed hyperplastic pearly thickening. Microscopically this consisted of a laminated deposit of connective tissue with marked hyaline metamorphosis. Small isolated tubercles on the surface of the intestines presented an identical structure. The capsule of the liver showed much less hyaline change, but contained numerous caseous foci; the great omentum was not detected; tubercle bacilli were demonstrated in the capsule of the liver.

Here the thickening of the peritoneum was very similar to the hyaline change in the simple form of inflammation and at first sight might be mistaken for it, but the main difference is that, to some extent, areas of caseation were superadded. In the hyperplastic tubercular peritonitis the ascites is not likely to be so great as in the simple form, and may indeed be absent, while fibrous bands of adhesion are more numerous. So far as the distribution of the lesions is concerned the disease is strictly comparable to the non-tubercular form, for in both we may have small isolated nodules scattered over the peritoneum, or thick sheets of hyperplastic material. The two forms present an additional similarity in that the process is not necessarily confined to the peritoneum, but may extend to the pleuræ and pericardium. I have met with two cases of this type, and Strajesko[11] has recorded a case which is important, since it proves that the multiple involvement of the serous membranes of Curschmann's "icing-liver" type may be due to tuberculosis, a fact which was hitherto unknown. A similar case has been recorded in this country by Herrick.[18]

I would like here to emphasize the similarity in appearance between the simple and the tubercular forms of hyperplastic peritonitis. Many of these cases come to operation and confusion is liable to arise. It is not likely that the tubercular form will be mistaken for the non-tubercular, but I am convinced that the reverse not infrequently occurs; particularly when isolated fibrous nodules are seen upon the surface of the intestines or about the liver and diaphragm is the case likely to be regarded as tubercular. As in the tubercular form the mere fact of opening the abdomen seems, to some extent, to mitigate the process, and it is not unlikely that many of the so-called cures of "tuberculous peritonitis" have occurred in this type of case. The resemblance between the two forms may be so striking that only a microscopic examination of the nodules with the demonstration of the presence or absence of the tubercle bacilli will reveal the true nature of the case.

Another type of chronic hyperplastic peritonitis of tubercular origin is of great practical importance. I refer to a more or less localized form in which a tumor-like mass is produced. The great omentum may be matted into an irregular lump, or the process may be most marked in some part of the intestinal tract, notably about the appendix and cecum. In other cases the small and the large intestines have been found contracted into a ball. This form is liable to be mistaken for carcinoma. Lartigau[12] has collected the literature on this subject. It is important to recognize this variety, for many cases are amenable to operation and of course the prognosis is very much better than in the case of carcinoma. In a case reported by Lartigau of a very peculiar form of hyperplasia without caseation, the disease was proved to be tubercular, and was entirely confined to the wall of the bowel without accompanying peritonitis. Extensive peritoneal adhesions may, however, form about a similar tubercular mass involving the cecum, as in a case reported by Koerte.[13] In other cases the great omentum has been involved as well, as shown by Routier[14] and Tédenat.[15] While these cases are examples of a local or sporadic distribution, they are undoubtedly etiologically of the same nature as the diffuse form with effusion, for the *Bacillus tuberculosis* has been detected in the hyperplastic tissue.

It is important to recognize the existence of this peculiar form since in the early stages it is perfectly amenable to operative measures, while if allowed to go on the process spreads, extensive adhesions form, and it becomes impossible to remove the mass. I believe

that in all cases of tumor-formation about the ileocecal region or in the mid portion of the abdominal cavity an exploratory laparotomy is justifiable, for if a too ready diagnosis of carcinoma be made and the patient left alone he is nearly always condemned to death by intestinal obstruction or dissemination of the tubercular process, while in suitable cases operation may be followed by complete cure.

A third form of hyperplastic peritonitis is that associated with carcinoma. It is, of course, well recognized that sero-fibrinous or fibrino-purulent peritonitis may arise as a complication of carcinoma of the peritoneum, but, so far as I am aware, scarcely any attention has been given to the hyperplastic form in this connection. Nothnagel[16] refers to an indurative and deforming peritonitis as occasionally met with, but I have been unable to find any extended references to that particular type associated with hyaline degeneration. The cases afford great similarity to those already described, for there is a chronic course, more or less cachexia and ascites, with the formation of nodular masses in the abdominal cavity. One such instance came under my notice recently:

Case 4.—Male, aged 46; alcoholic and syphilitic; for three or four years had been complaining of palpitation of the heart and oppression in the chest. Three weeks before being admitted to the Royal Victoria Hospital he noticed swelling of the abdomen and of the left leg. On admission the abdomen was tense and greatly distended, with evidence of fluid. The appetite was poor and there was tendency to constipation. He suddenly developed pain in the abdomen and died in a few moments.

Autopsy.—A very singular condition of things was found at autopsy. The peritoneal cavity contained 4300 c.cm. of straw-colored fluid with flakes; the mesentery was shortened, thickened and pearly in appearance; the great omentum was much contracted and contained a number of firm nodules about the size of walnuts and of a yellowish color, with some congestion of the capillaries on the surface, and lay in close contact with the stomach as a firm nodular cord extending across the abdomen midway between the xiphoid and the umbilicus; the parietal peritoneum was thickened, especially in the upper part of the cavity and was of a pearly-white, hyaline appearance, presenting a multitude of shallow depressions or pits. In other parts where the hyaline change was not so diffuse it formed tree-like masses about the vessels. Here and there on the intestines were small flat pearly nodules. Similar nodules were seen on the suspensory ligament of the liver and on the under surface of the diaphragm. Along the mesenteric attachment of the descending colon were numerous nodular growths identical with those in the great omentum. The stomach was contracted and its wall hypertrophied. On the lesser curvature posteriorly near the cardia was a chronic cancerous ulcer. There was some hyaline thickening of the liver capsule, especially near the gall bladder. On the surface of the spleen were scattered thin fibroid plaques of pearly-white hyaline appearance.

Microscopic Examination.—This showed that the peritoneal membrane presented proliferation of fibrous tissue with hyaline change. The primary condition was a scirrhous cancer of the stomach extending into the peritoneum; the nodules in the great omentum and mesentery were scirrhous cancer, as were also the hyaline-looking plaques on the surface of the intestines. It is singular that there were no metastatic deposits in the viscera, but instead a diffuse dissemination of carcinoma throughout the peritoneum. Death ensued from pulmonary infarct due to a loosened thrombus of the left iliac vein.

The exact nature of the peritonitis which complicates carcinoma is as yet obscure. The more acute and the subacute forms in some cases are due to perforation of cancerous ulcers in the hollow viscera or to secondary infection of the cancer-mass and its neighborhood. The hyperplastic form may possibly depend on infection with microörganisms of low virulence, but it is debatable how far the overgrowth of tissue is dependent on inflammation. It is more probable that, in addition to an inflammatory process, we have diffuse carcinosis leading to marked proliferation of fibrous tissue, such as is usually the case in the scirrhous variety. The combination of inflammation with neoplasia would exactly reproduce the picture of hyperplastic peritonitis. In the case in question the ascites resembled an inflammatory exudate rather than a transudate, and, in fact, no condition was found at autopsy which could have brought about obstruction, either in the portal system or in the inferior vena cava. I am strongly inclined to think that a secondary infection of the peritoneal cavity had taken place, possibly from the carcinomatous ulcer of the stomach. Until more cases are studied, however, many of these questions can not be settled definitely.

From a consideration of the foregoing cases I would suggest the following as a suitable classification for the disease:

Chronic Hyperplastic Peritonitis.

Sporadic.		Diffuse.		
Simple.	Tuberculous.	Simple.	Tuberculous.	Carcinomatous.

DIAGNOSIS.

In conclusion a few words as to diagnosis may be given. The local forms of hyperplastic peritonitis, with the single exception of that form affecting the cecum or other parts of the intestinal tract, give rise to no manifestations that suggest their presence. The discovery of a large nodular mass in the neighborhood of the cecum of very chronic development and without marked signs of cachexia should always suggest tuberculous hyperplastic peritonitis, or at least involvement of the intestinal wall. When the process is diffuse four diseases come specially into mind: (1) simple chronic hyperplastic peritonitis, (2) tubercular peritonitis, (3) cirrhosis of the liver, and (4) carcinoma of the peritoneum, since in all there may be ascites, with abdominal pain and in most the formation of nodular tumors in the abdomen. Simple chronic hyperplastic peritonitis may be suspected if there be extreme ascites, and little or no anasarca, especially if with these signs there are evidences of an adherent pericardium or right pleura. A history of previous infective disease, gastric or intestinal ulcers, gallstones, will be suggestive of this condition.

The clinical picture is often dominated by signs of adherent pericardium or perihepatitis, and, in fact, unless perihepatitis be present the disease can probably not be diagnosed. Portal congestion is absent and there is no marked disturbance of digestion, no hematemesis nor melena; jaundice does not occur unless gallstones be present. The liver may be enlarged or small, but is rarely warty. In the tubercular form the ascites is not so great and the fluid is more apt to be sacculated, while abdominal pain and tenderness are more marked. Pigmentation of the skin has been observed. Careful examination should be made of the lungs, glands, testes, ovaries and fallopian tubes for evidence of a primary tubercular focus. The disease is more common in females than is the simple form. The distension of the abdomen is often uneven, owing to the irregular dilatation of the intestines. A hemorrhagic exudate is more in favor of tuberculosis or carcinoma than the simple peritonitis. Hectic fever is not uncommon, but cases may run without fever and intestinal symptoms may be in the background. Tuberculin injections may be tried in suitable cases. In cirrhosis of

the liver, dyspeptic disorders, alcoholism or syphilis are prominent etiological factors; portal stasis is marked; nausea, vomiting, hematemesis, melena and the various signs of portal obstruction differentiate this form from the "icing-liver" type of Curschmann. The great omentum is never nodular, as in the form of chronic peritonitis. Jaundice occurs in 27 per cent. of cases; the liver may sometimes be felt to be warty. Cerebral manifestations are not uncommon. As Hale White[19] has pointed out, when tapping becomes necessary the patient rarely lives long. On the contrary, in simple hyaloserositis the abdomen may be tapped a great number of times and the patients may live for years in comparative comfort.

In carcinoma the patient is usually advanced in years and cachexia is marked. Careful examination of the stomach and, in the female, the ovaries should be made; a hemorrhagic or chylous or pseudo-chylous ascites is in favor of carcinoma. The hemorrhagic exudate is somewhat less frequent in the tubercular form. It is doubtful whether the presence of peritonitis, unless of the perforative variety, can be diagnosed with certainty when complicating peritoneal carcinoma. Abdominal pain and tenderness might in some cases suggest it or the presence of a friction rub. In carcinoma the disease is fairly rapid.

TREATMENT.

Complications or special symptoms may call for appropriate remedies, but the treatment is essentially surgical. It has long been known that tuberculosis of the peritoneum has been apt to disappear after abdominal section, and indeed without it, and a simple hyperplastic peritonitis has been occasionally benefited by this procedure. Especially in the form of hyperplastic tuberculosis localized to the cecal region resection of the affected part may result in complete cure. Operation in some cases may be called upon to relieve obstruction.

For the simple form, tapping is usually necessary at increasingly frequent intervals. With regard to medicinal measures, diuretics, especially caffein, have been recommended in the hope of diminishing the ascites. The patients should be kept in the best hygienic surroundings.

In the carcinomatous peritonitis the outlook is, of course, hopeless.

DISCUSSION.

Dr. W. M. Welch, Baltimore—Dr. Nicholls' description and classification of these interesting forms of chronic peritonitis are most commendable. I have been interested in a number of the forms which he describes, especially in the diffuse chronic thickenings of the peritoneum associated sometimes with carcinoma, particularly with cancer of the stomach and of the ovaries. In some of these cases the fibrous thickening is limited to the wall of the stomach, in others it may affect a large part of the peritoneum. It may be impossible to recognize the existence of cancer in some of these cases without careful microscopic examination. There may be no circumscribed tumor, no ulceration of a mucous surface, and the nests of cancer cells may be relatively small and far apart. The disease may present itself to the naked eye as simply a diffuse fibroid thickening of the gastric and intestinal walls, with perhaps similar thickening of the peritoneum elsewhere. Both simple and colloid types of carcinoma may appear under this form.

There is another condition to which I should like to call attention in this connection, namely, the occurrence of richly vascularized, thin layers of new connective tissue, particularly on the pelvic peritoneum, associated with small hemorrhages and blood pigment. This condition is analogous to chronic hemorrhagic pachymeningitis, the morbid process being of the same general nature in both affections.

The chronic proliferative forms of peritonitis associated with tuberculosis are, of course, well recognized. There occur, as Dr. Nicholls has pointed out, diffuse or more circumscribed forms of peritoneal fibrosis, especially about the liver, but also over the spleen, the under surface of the diaphragm, and elsewhere, the etiology of which is very obscure.

Dr. E. R. LeCount, Chicago—I have met several cases. One of them had to do with a liver which was encased in a shell, resembling that of a cocoanut, from which the liver could easily be lifted out; the capsule then maintained its former shape when laid on a flat surface.

I think Dr. Nicholls is to be complimented in his arrangement of these diseases, and for not becoming entangled in the subject of "pseudo-cirrhosis."

Dr. A. G. Nicholls, Montreal—The reference made to pachymeningitis, by Dr. Welch, as a disease having some of the anatomic peculiarities of this *zuckerguss* condition, is interesting, and I am of the opinion, as he is, that there is a close analogy between this disease and what may be termed "pachyperitonitis." Cases such as I have described are not entirely new and the only point on which I would claim novelty is in the recognition of the fact, which has not been brought out before, that the *zuckerguss* form of peritonitis has at least a threefold etiology—simple, tubercular and carcinomatous.

THE GROWTH OF THE TUBERCLE BACILLUS AND ORGANISMS RESEMBLING IT ON FRUITS AND VEGETABLES.*

M. J. ROSENAU, M.D.

DIRECTOR HYGIENIC LABORATORY, U. S. MARINE-HOSPITAL SERVICE.

WASHINGTON, D. C.

At one time the tubercle bacillus was looked on as standing in a class by itself, sharply differentiated from all other micro-organisms, but not long after its recognition two important points came to light; first, that there are other organisms, especially the streptothricæ, that have the power of producing lesions resembling the tuberculous granulomata; and secondly, that there are other organisms resembling the tubercle bacillus in some of its biologic and staining characteristics.

The fact that the tubercle bacillus stains with difficulty and decolorizes with corresponding difficulty was for a long time regarded as peculiar to this organism. This staining peculiarity was looked on as a definite and final test, quite as specific as a chemical reaction. But now we know a whole group of acid-proof bacteria widely distributed in Nature, that resemble the tubercle bacillus closely enough in certain features to cause confusion and errors in diagnosis. These organisms are found in butter, milk, on grass, in manure, and even in certain lesions in the body.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. Alfred Stengel, L. Hektoen and Winfield S. Hall.

They have been found, for instance, in an ovarian cyst and in the nasal secretion of healthy and diseased mucous membranes; also in sputum. They stain with carbol-fuchsin exactly similar to the tubercle bacillus and resist the decolorizing action of alcohol and acids, that is to say, they are acid-proof.

While these bacteria may readily be distinguished from the true tubercle bacillus by their cultural characteristics or by their pathogenic action in animals, it may readily be seen how they have been the source of error in diagnosis and how they have further complicated the difficult problems of tuberculosis. Some of these organisms stain and decolorize more readily than others. That is to say, they do not all have the same high degree of acid-proof qualities presented by the tubercle bacillus itself. Therefore this also causes confusion in the study of leprosy, especially in staining the *Bacillus leprœ* in nasal secretions.

We can no longer make a scientific diagnosis of tuberculosis by simply staining the bacilli in the sputum, although for clinical purposes this method remains useful. It is necessary to isolate the organism in pure culture and study its pathogenic action on animals. This takes a long time, often a matter of weeks and months.

Therefore, the problem confronts us of finding a media on which the tubercle bacillus will grow quickly in order to save time, and thereby render the process of cultivation a practical one for clinical work.

Of the various media tested we have so far had best success with certain vegetables and fruits. While this work which I am now presenting to you is not yet completed, I am at present able to state that there are vegetables on which the tubercle bacillus grows quite as well, if not better, than on potato. Beet and cauliflower seem especially favorable. Sometimes the growth appears more quickly on these vegetables than on potato.

A good growth of the human variety has been obtained on the following: potato, cabbage, cauliflower, turnip, carrot, squash, celery, egg plant, beet and radish, and a small or doubtful growth on apple, onion, cocoanut and pineapple.

It is nothing new to grow micro-organisms on vegetable media, although I have not heard of anyone growing the tubercle bacillus on the various substances mentioned, except potato.

For comparison with the tubercle bacillus, I herewith present for your consideration growths on the same fruits and vegetables, of avian tuberculosis, bovine tuberculosis, Karlinski's bacillus of nasal secretion, Rabinovitch's bacillus of butter and margarine, and Moeller's grass bacillus. These growths present a very suggestive picture. We seem to have here a tubercle group, just as we have a colon group. There is a very considerable difference between the extremes of this tubercle group, also several remarkable points of resemblance. If the tubercle bacillus of man has been specialized by a process of evolution from the more lowly grass bacillus of Moeller, or if the grass bacillus is a degenerate saprophytic form of the tubercle bacillus there are several missing links between the two. The saprophytic acid-proof organisms resembling the human tubercle bacillus grow readily on the ordinary media used in the laboratory, both at room temperature and in the incubator. A visible growth is often obtained over night. They also have more color than the tubercle bacillus, usually a salmon-red or yellowish tint. The human tubercle bacillus grows as a crinkled, rugous, dry, mould-like mass. Some of the cultures of the acid-proof organisms resembling the human bacillus have a dry, corrugated growth on various fruits and vegetables which is very suggestive.

These few remarks are only given with the specimens herewith presented as a preliminary note of the work now being done on this group of micro-organisms in the hygienic laboratory of the Marine-Hospital Service, and a further report will be made at a later date.

DISCUSSION.

DR. JOSEPH MCFARLAND, Philadelphia—Did the growth take place in direct proportion to the amount of sugar these vegetables contained?

DR. C. A. SMITH, Atlanta, Ga.—How does Dr. Rosenau prepare his media?

DR. M. J. ROSENAU, Washington, D. C.—The media are prepared just as we prepare potatoes as a culture medium in test tubes. With an apple corer I cut out a solid plug of the fruit or vegetable, this cylinder is cut in two and each half is placed in a test tube in the bottom of which is some 5 per cent. glycerin bouillon. This is then sterilized fractionally on a number of successive days. Those we prepared to keep through the winter were saturated with glycerin bouillon by filling the test tube almost full, and when we are ready to use the media we pour off the excess of fluid, leaving only enough at the bottom to keep the vegetable moist.

As to the relation between the amount of sugar in the different vegetables and the growth obtained thereon, this is a very interesting feature. I have not gone into this at all yet, but am doing so from another standpoint and hope to be able to say more about it another time.

THE DIAGNOSIS OF BRAIN ABSCESSES.*

HERMAN H. HOPPE, M.D.

Lecturer on Nervous Diseases, Medical College of Ohio, University of Cincinnati; Professor of Nervous Diseases, Clinical School, City Hospital, Medical Department, University of Cincinnati; Neurologist to City Hospital.

CINCINNATI, OHIO.

We encounter difficulty in diagnosing brain abscesses in two ways: First, in determining whether or not an abscess is present, and in the second place, in locating it. These difficulties are entirely out of proportion to the difficulty found in diagnosing other brain lesions, say, for instance, tumors and cysts. In the former condition the symptoms are not only frequently obscure and indefinite, but for a considerable period may be absent altogether; the abscess may be in a latent state. In tumors and cysts time is not of such very great importance, a few days or a few weeks may elapse and the diagnostic points may be allowed to develop themselves, without there being any added perils to the patient. In abscess, however, time is of great importance, a few days, even twenty-four hours, may determine whether or not the individual's life can be saved. It is in the latent or developmental period of a brain abscess that surgical interference offers the best chances; when the abscess has ruptured and the stage of manifest development has set in, the outcome of the surgical interference is, to say the least, very doubtful. The great problem, therefore, is to be able to diagnose the presence and if possible locate an abscess in its latent period or at least in the very earliest stage of its period of positive manifestation.

In order to bring this subject before the section I am going to cite for you a number of cases which were either operated on or which were suspected of having brain abscesses and in which the subsequent develop-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

ment failed to confirm the suspicion. The importance of the subject is manifest and we all are in the predicament very often in just such cases as the following, as to whether we shall advise surgical interference or not. The question is entirely different in brain tumor. In the latter cases the question of surgical interference never arises unless the tumor is located in the cortex, but in every case of abscess we may at least hope that surgical interference can remove the trouble. There are but two solutions to every abscess of the brain, death or surgical interference. Rosl raised a two-fold objection to operations for abscess: 1, The tendency of abscesses to become encapsulated; 2, the difficulty of diagnosis. There can not be any doubt about brain abscesses becoming encapsulated, but we know from clinical experience as well as from the record of autopsies, that the single abscesses, at least, do not remain encapsulated. The same process of softening which is seen around brain tumors and cysts also occurs around the brain abscess, and invariably death results from rupture either into the lateral ventricles or through the cortex. Superficial abscesses on very rare occasions have been known to rupture through the cribriform plate of the ethmoid or the roof of the middle ear, or even through an old fracture, but these fortunate exceptions can not enter into consideration of treatment. The second objection, the difficulty of diagnosis, of course, is valid, but should only urge us to make greater efforts toward the relief of a condition which may offer a favorable surgical outcome. The difficulties are not as great as formerly and at times the diagnosis is even easy.

Given a certain group of signs and symptoms which lead us to suspect the presence of a brain abscess, the first point is the tracing of the source of infection. Bergman says that without the streptococcus pyogenes aureus there can not be a brain abscess. If this is correct then we should at least be able to find the source of infection. Now this is notoriously difficult. Pus-forming organisms always come from without. This is the most important and the first point; with the development of bacteriology the theory of idiopathic abscesses has collapsed.

BERGMAN'S CLASSIFICATION.

According to their origin Bergman divides brain abscesses into four groups, and for the purpose of studying the difficulties in the latent period the consideration of the etiology offers the best results.

1. Traumatic abscesses caused by an open scalp wound or a fractured skull.
2. Those abscesses resulting from a purulent inflammation of bone or bony cavities.
   (*a*) Otitic abscesses.
   (*b*) Rhinogenetic abscesses.
   (*c*) Abscesses due to caries of the bones of the skull.
3. Tubercular abscesses.
4. Metastatic abscesses.

TRAUMATIC ABSCESSES.

In traumatic abscesses the most important point to remember is that there must be some direct communication between the cranial cavity and the external world, an open channel through which the infection may travel. It is not necessary to have a fracture of the skull, as Case 1 will illustrate, but an open wound is absolutely necessary. I am well aware of the fact that there are cases on record of abscesses following mere contusions of the scalp, streptococci being brought to the bruised part by the cerebral arteries, but for practical purposes in suspected latent abscesses we should adhere to the fact that there can not be a traumatic abscess without an open channel of infection. This is usually an open scalp wound that has become infected, but it is not at all uncommon to have an abscess follow a fracture at the base of the skull and then the open channel is by way of the auditory canal, pharynx, or the frontal sinuses. In recent abscesses, following soon after the injury, this will not offer any difficulty, but in latent abscesses occurring weeks or months after an accident this point may be overlooked, especially where the original symptoms and signs of basilar fracture have not been very marked.

Case 1.—M. R., female, aged 22, single, admitted to the Cincinnati Hospital Jan. 22, 1901. Mental condition such that history was unobtainable. Said to have been struck on the head by a chair on New Year's eve, since which time she has not been well. Further history than this can not be obtained at present time.

Examination.—Temperature, 100.4; pulse, 80; respiration, 20. When not disturbed lies quiet and seems to be somewhat stupid. Easily aroused, and apparently understands everything said to her. Can tell the name of some objects, while she can not of others. Knows the use of some of the objects she can not name. Can write (her name at least) but holds the pen loosely, and seems to have lost the finer movements of the fingers. Can not read, but attempts to spell out the words, calling almost every latter "C" or "R." She is fairly well developed and nourished. Swelling on left side of head above the ear, about three inches in diameter, the most prominent point of which is about two inches from the median line. Fluctuation is easily obtained. Pressure over this area causes a contraction of muscles of same side of face. Pupils moderately dilated, equal and react sluggishly to light. Muscles of eyes not affected. When lying quiet with eyes closed, there is an angle between upper and lower lids of right eye, but when asked to do so, can completely close both eyes. There is no ptosis. With above exceptions there is a right facial paralysis; absence of nasolabial fold, can not whistle or show teeth, saliva drools from right corner of mouth and tongue is apparently protruded to the right. Tongue slightly coated. Lips dry and cracked. Very slight paresis of right arm. Left arm and both legs all right. Reflexes normal. Knee-jerks diminished. Sensation normal (rough test). Babinski's reflex-flexion. Appetite poor. Bowels have moved and she has voided urine since admission. Urine amber, acid, 1018. Blood count: Reds 5,500,000; whites 13,400.

January 25: Temperature range a little lower. Paresis of right arm has increased. Aphasia about same; speaks a few words clearly and distinctly; writes her name and copies letters very well; does not do so well from dictation.

January 26: Is much better this morning; paralysis of face much better; when she laughs the face wrinkles almost equally on both sides; both corners of the mouth retract, but the right drags a little; strength in right arm better; holds pencil very well and writes much better; talks better and seems brighter.

January 27: Aphasia about the same; temperature 97.

January 28: Unchanged; temperature 99.8 last night.

Operation.—The operation was performed by Dr. Ransohoff. Chloroform. A semilunar incision was made in scalp through the fluctuating mass about four or five inches long, convex upward, center just about over the ear. Flap turned down. Upper part of temporal muscle softened and broken down into a nasty-looking granulating mass. No pus found. Cultures in blood serum and bouillon were taken from this mass. There was a small softened area in the skull just over the lower part of the Rolandic fissure, from which bloody serum was oozing. Trephine applied here and button of bone about size of quarter removed. This opening was enlarged by rongeur forceps until about four inches long and three wide. Dura very much thickened, red and injected, as if the site of recent inflammation over an area about 1½ inches in diameter over the lower end of fissure of Rolando. Cultures taken. Incision through dura, and aspirator needle thrust into the brain in various directions. No pus found. Veins somewhat dilated,

dura not sewed. Inner surface of scalp flap curetted and washed with 1-2000 bichl. Strands of silkworm gut passed through from one end of incision to other, for drainage. Scalp sutured with silkworm gut. Dry dressings.

January 29: Seems a little better this morning.

January 30: Aphasia much better, can say many words which she could not before operation. Temperature normal.

January 31: Aphasia still improving; wants to get up; KI. ordered.

February 1: Aphasia almost entirely gone; sits up in bed; appetite good.

February 2: Improving rapidly; facial paralysis and aphasia nearly gone.

February 4: Head dressed; sutures not removed; no pus or bogginess.

February 12: Second dressing to-day; sutures removed; small drop of pus in lower end of incision; no bogginess; temperature has been up for past 2 or 3 days.

February 28: Complains of headache and pain over mastoid; nothing abnormal found in ear.

March 10: Improving nicely, although still has the pain over mastoid and a little above.

March 21: Discharged well.

In this case the abscess occurred without a fracture directly under the seat of a badly-infected scalp wound; the abscess was extra-dural and the location of the wound gave rise to the suspicion of an abscess. Had the scalp wound been located over an indifferent portion of the cortex, it would, to say the least, have given rise to a great deal of difficulty of diagnosis and might even have been overlooked.

This case illustrates another difficulty; we may have abscesses of the brain, following a scalp wound, without a fracture of the skull being present; the infecting agent can penetrate through the skull probably in this case by medium of a localized ostitis, and still this does not explain the penetration of the internal table which was intact.

CASE 2.—George Kling, aged 49. Was admitted to strong ward with diagnosis of delirium tremens. Patient has alternating periods of stupor and delirium. Can be aroused only slightly. History obtained from police stated that he was struck on head in a fight.

Examination.—Marked tenderness over right side of head, just above the ear; marks of contusion; paresis of left side of face, slight ptosis of right eyelid; right pupil smaller than left; pulse 72, temperature 99½. On account of mental condition, unable to make a more careful examination, but the patient is able to use both arms and legs.

There was gradual increase in the stupor, the temperature gradually rose to 103; on the fourth day a spastic paresis of right arm set in; on fifth day temperature rose to 104½. An abscess of the left psycho-motor area was suspected.

Operation.—A linear fracture of skull was revealed, tearing of dura mater and contusion and laceration of the brain tissue, but no abscess or pus formation. Recovery complete.

Here we have all the indications of a surface abscess: fever, delirium, low pulse, monoplegia, surface tenderness and no scalp wound. The operation revealed a linear fracture of the skull, a torn dura mater and a badly lacerated cortex without the slightest inflammation or pus formation. This last case is specially instructive. Our caution and delay in operating was justified by the results. It was only when there was no improvement, but rather an increase in the symptoms, that we decided on an operation. We can readily see how much better such an individual would be without an operation as far as the future is concerned. There is always more or less danger from shock, from cerebral prolapse, with its attending scar and subsequent danger of epilepsy, to say nothing of the large aperture in the skull which remains after the operation.

When a violent headache, mental hebetude, mild delirium, increasing somnolence and a slow pulse follow soon after an accident to the head, when the scar is still fresh and there is undoubted evidence of a recent injury, the diagnosis even then can be very difficult. I need not cite successful operations or the history of suspected abscess which turned out to be localized meningitis. They are too common an everyday occurrence in large general hospitals to require especial mention. But when a long time, months or even years, have elapsed between an injury and the development of symptoms which point to brain abscess, the difficulty becomes very great. Case 3 is of this character.

CASE 3.—Charles Legnore, aged 23, admitted for conjunctivitis. Had an accident to head followed by unconsciousness 18 months before. States that he has had epileptic seizures for 3 years, at intervals of once a month. Denies syphilis. Transferred to neurological service in a stupor after a series of convulsions. These convulsions began about a week ago, always beginning in left side of face and then extending over left side of body, afterward becoming general.

Examination.—Pain and tenderness over right mastoid and occipital region. Percussion brings on a convulsion in left facial. Stupor—can be aroused only very imperfectly; when put on his feet staggers and complains of vertigo; falls to left side. Marked paresis of left side of face, of left arm and left leg. Complete anesthesia and loss of reflexes on left side of body. No optic neuritis. Left hemianopsia seems to be present. Examination in other respects negative. Temperature normal. Urinalysis negative. Pulse 66. One week after admission to neurological service there was complete paralysis and anesthesia of left side of body.

Operation.—Was operated on by Dr. Ransohoff for suspected abscess of the right temporal lobe. Operation revealed a perfectly normal condition of meninges and cortex. Aspiration in all directions, no pus. Mental condition and delirium cleared up after operation. Patient became bright and cheerful. Paresis diminished very much. Epileptic convulsions occurred only occasionally. The operation revealed no cause either for convulsions or for the paralysis.

Here we have all the signs of a cerebral localized abscess; not one is wanting, nor is there any aberration in the history of the case, and still the operation reveals no abscess. The case remains under observation six months after the operation and is discharged as a hemiplegic with no apparent cause for the hemiplegia that can be found, unless we look on it as a very small abscess or area of softening in the internal capsule, probably the size of a hazel nut. But how such a small focal lesion could produce such violent general symptoms is a mystery. A similar case is reported by Oppenheim. Early traumatic abscesses are usually extra-dural or intra-dural, practically cortical in location and usually are detected by their focal symptoms or, what is more common, localized tenderness of the skull on percussion. But latent abscesses are almost invariably subcortical and are situated in the white substance just beneath the cortex. There is always a layer of healthy bone or brain tissue with intact meninges between the source of infection and the abscess. This increases the difficulty of diagnosis, not only before the operation, for we all know that subcortical lesions produce less manifest signs than cortical ones, but also at the time of operation when the surgeon is confronted with healthy calvarium, meninges and a normal-looking cortex.

One more point before leaving the consideration of traumatic abscess. Gunshot wounds, knife thrusts or compound comminuted fractures are more apt to be followed by abscesses than simple fractures. Moreover, wounds attended by a longer period of suppuration are

more apt to be followed by latent abscesses than those which have closed quickly.

ABSCESSES FOLLOWING MIDDLE-EAR DISEASE.

The difficulties in abscesses following caries of bone, especially middle-ear disease, are again two-fold. First, the difficulty of determining the presence of an abscess, not only in the acute, but especially in the latent period; secondly, of locating the abscess. In the period of acute manifestations of mastoid inflammation, especially in children, the signs and symptoms of the mastoid disease may simulate perfectly those of brain abscess, especially if the case is bedridden. The only absolute signs before the operation of brain involvement are cerebellar signs of a positive nature, or if the left side be involved, the occurrence of sensory aphasia. In doubtful cases, however, the bone and ear disease should first be attended to. Sinuses should be looked for and if the general signs of brain abscesses do not clear up after the operation, then a secondary operation may be indicated. Abscesses from middle-ear trouble are, however, notoriously latent, and this fact gives us great difficulty. Let me illustrate by an appropriate case.

Case 4.—Mary Corcoran, aged 20, American, single, cigar maker, family history negative. Had a fall on head in childhood; there was, soon after, a discharge from right ear. Always had nasal and throat catarrh. In July, 1901, had a mastoid operation which was successful; no more discharge from this ear. Since then complains of headache, pain and soreness in occipital region on right side. Pain in the head is increased by sneezing and coughing; has vertigo and staggers at times like one intoxicated; usually staggers toward right side and says that she would fall if she did not grab hold of something. There is a constant fear of this vertigo and staggering. No vomiting; general health is very good. Sleeps and eats well; no constipation.

Examination.—Mental condition good; no hebetude; no impairment of memory; examination of right ear shows a healthy condition of the bones and mastoid process has healed completely. Ophthalmoscopic examination revealed some slight congestion of the veins of the right papilla, nasal margin sharply defined. Temporal margin a little indefinite. In every other respect the examination is negative.

Treated with tonics and protoiodid. All doubtful cerebellar symptoms disappeared after three months of treatment.

The most important contribution concerning brain abscesses in middle-ear trouble has been given to us by Koerner. He proved that we could accurately locate the seat of the abscess in the brain if we knew which part of the temporal bone was diseased. Koerner made autopsies on 109 cases of brain abscess; 86 times the temporal bone was diseased to the dura mater, 8 times half way through the bone, and in only 15 cases was it healthy. In 40 abscesses, 38 times the seat of abscess was immediately below the diseased bone, and the dura was involved. The dura was frequently adherent to brain and diseased bone.

If the roof of the middle ear is diseased the abscess is in the temporal lobe. If the mastoid cells or the posterior portion of the petrous portion of temporal lobe is the seat of inflammation the abscess is in the cerebellum; the middle lobe of cerebellum is involved if this purulent inflammation passes through the semi-circular canals. Bergman speaks strongly in favor of the above method of localization.

Another point in diagnosis is, that otitic suppuration when associated with a cholesteatoma, whether the latter be primary or secondary, is more apt to cause abscess of the brain than an uncomplicated one. The reason for this is given by Kirchner. The cholesteatoma penetrates the bone; in its growth ramifies the Haversian canals for a considerable distance around its base; makes the bone thin and friable, fills it with large cavities, and in this way renders the corrosion by the pia an easy matter and paves the way for an abscess. In addition to this the pus is dammed back by the cholesteatoma and the breaking through and the corrosion becomes an easily accomplished fact. In these cases the pus is thus decomposed and cholesteomatous masses float in and on it. Virchow, in 60 cases of otitic brain abscess, found one-fourth with cholesteatoma. Two other factors predispose to the formation of otitic abscesses: *a*, the course of suppuration in acute or subacute exacerbations, the pus being fetid; *b*, the presence of large granulation masses in the middle ear, or deep in the external ear; the granulation masses acting as a dam to the pus. Thus we see we can obtain important diagnostic data from the examination of the external ear. Another important diagnostic point in otitic abscesses is the fact brought out by Koerner, that otitic abscesses are oftener on the right side than the left. Herzberg showed that the transverse sinus on the right side lies deeper in the bone than on the left. Koerner proved this to be the case in 70 per cent. of his autopsies. This causes the bone, therefore, to be thinner and more easily perforated by a cholesteatoma or fragment of dead bone (by the suppurating process).

When the origin of the abscess is in the roof or attic of middle ear, the bone having become inflamed or corroded, the first step is a purulent pachymeningitis, and this is followed either by an extra- or intra-dural abscess. The intra-dural abscess is at first connected with the dura mater, afterward becomes separated by becoming encapsulated and then becomes subcortical in the temporal lobe. Often we have both extra-dural and intra-dural or brain abscesses at same time; this is very important to remember (E. Hoffmann). We can diagnose an epidural or extra-dural abscess (Bergman) only by the following signs; by external signs when the pus escapes either through middle ear, through temporal bone or mastoid cells. Abundant flow of pus, of short duration, will arouse suspicion of abscess, especially if the signs of previous increased intra-cranial pressure disappear with flow of pus. Discharging fistulæ and especially edema or fluctuating abscess over the mastoid bone, lead to diagnosis of an epidural abscess of the middle or temporal fossa.

The difficulty of locating an otitic abscess is increased by the fact that middle-ear suppuration is often associated with suppuration of the mastoid process. Then we must look for caries or ostitis, because if the latter process is either in the antrum or in the mastoid it is liable to determine the seat of abscess.

A badly located or a small tympanic perforation is apt to cause brain abscess by damming back the pus. Otitic abscesses have an imperceptible and unknown (as to time) beginning; never sudden; trauma plays no rôle.

Otitic cerebellar abscesses are very difficult to diagnose and are frequently complicated with sinus thrombosis and lepto-meningitis and masked by the latter. We look for cerebellar abscesses in caries of the sigmoid fossa, of the sulcus transversus, of the labyrinth and the mastoid cells (Koch). Koch has proven that cerebellar abscesses before the age of 10 are rare (2 out of 105). Hence, prior to this age we must look for tempero-sphenoidal abscesses.

The cerebellar abscesses are found in the lateral and at times in the median surface of the hemispheres and

usually in the anterior lower surfaces, and in such a way that caries of the sigmoid sulcus cause abscess of the lateral and the caries of the labyrinth, of the lower median surface.

Koch divides symptoms of cerebellar abscess into groups according to three types of abscess:

1. Diagnosis made from marked cerebellar focal signs.
2. Marked signs of general brain pressure with but few and indistinct focal signs.
3. Neither local nor general symptoms are well marked, but the nature of the suppuration is in the mastoid region and the finding of fistulous openings through the dura leads to discovery of the abscess in the cerebellum.

The general symptoms are those of general brain pressure, but the pulse is very slow, the vomiting rare and optic neuritis occurs in but one-fourth of the cases. General pressure symptoms in cerebellar abscesses are due to dilatation of the ventriculi.

Rhinogetic abscesses are due to purulent processes in the upper nasal passages and the sinuses connected with them, viz.: The frontal, sphenoidal and maxillary. The route which the pus may travel is through the cribriform plate, along the horizontal plate of the ethmoid, or through the orbital cavity along the optic nerve. Simple operations, like the removal of polypi or of adenoid vegetations of the naso-pharyngeal plate, may, if followed by infection, cause cerebral abscesses. Just as in otitic abscesses, the inflammation and caries of bone of the above-named cavities cause an extra-dural and intra-dural abscess, a leptomeningitis and cerebral abscess, with an associated phlebitis of the sinus cavernosum, the difference being the greater frequency with which they are associated in the same case. The course of the inflammation from the malar sinus is through the orbit, by the way of the orbital veins. Out of 20 abscesses of the brain due to the above source of origin, 19 were found in frontal lobe and only one in the temporal.

This great frequency of abscesses of the frontal lobe following the above-named diseases makes the diagnosis easy when the general signs and symptoms of abscess are present. The localization is made from the seat of the pus infection, but, like tumors of the frontal lobes, the general and special signs may be absent. In a case on record in the Cincinnati Hospital service of Dr. Murphy, the boy was in the wards for fully sixty days for frontal sinus disease; he was up and about daily and was considered bright, active and intelligent. Two days before death he suddenly developed the general signs of a brain abscess, the operation revealed an abscess of the size of a duck's egg, discharging foul, offensive pus, which must have been present for months.

TUBERCULAR ABSCESSES.

In connection with tubercular abscesses two things are positive: One is that after the formation of a tubercle in the brain, a purulent inflammation may occur around the tubercle, and in reported cases the tubercle may completely break down, a microscopic examination being necessary to determine its tubercular origin, and, secondly, Koch has shown that the cause of the purulent inflammation is the dead tubercle bacillus. These tubercular abscesses may explain the so-called idiopathic abscesses and are of special interest in one direction, namely, that we may have all the indications of a cerebral abscess without any known traumatic or pus cause and still be justified in the diagnosis and the operation.

The difficulty in diagnosing tubercular abscesses is two-fold: In the first place there is an absence of all known causative factors in the case as it lies before us, and, in the second place, the general symptoms of tuberculosis overlap those of the brain trouble, and distort the clinical picture. These abscesses are very frequently in the cerebellum and then by producing basilar symptoms simulate very closely either a tubercular or syphilitic meningitis. A case of the latter character occurred in the Cincinnati Hospital on the service of Dr. Jos. Eichberg. Let me introduce a case which illustrates the difficulties named above:

Case 5.—F. E., male, aged 42. Admitted to the Cincinnati Hospital March 4, 1901, in a state of syncope and no history obtainable except that he had had headache for some time and had been dizzy; uses alcohol and tobacco. Patient very much emaciated; lies in bed and seems to observe everything that is going on; expresses no ideas; when spoken to does not always answer; sometimes it is several minutes before he replies; does not utter any connected phrases; complains of severe pain. Left pupil dilated; both react to light and accommodation. Paresis of right side of face.

Necropsy.—By Dr. D. I. Wolfstein. Brain when taken out was very soft and flabby, the left lobe being especially so on the cortical surface in an area extending downwards from the lower half of anterior frontal convolution to the base of the brain and bounded posteriorly by the fissure of Rolando, inferiorly by the Sylvian and anteriorly impinging on left inferior, frontal and middle frontal convolutions was an area of softening; after hardening in formalin this proved to be a globular mass, which could be shelled from its surroundings and which was hollow and filled with greenish pus. Brain tissue surrounding mass was also extensively softened; whether this is a broken-down tumor or a tubercular abscess microscopic examination must determine. The symptoms were aphasia, right facial paresis, some slight paresis of right arm and less of right leg, ataxia, and patient lay in a state of stupor. Macroscopic examination of pons revealed nothing abnormal, likewise in cord. Heart small and flabby. Lungs, left, tubercular, lower lobe full of miliary tubercles, and one small abscess. Liver fatty; spleen friable; kidneys small, hyperemic; extremities negative.

Histology.—Brain: From what was a cyst or cavity filled with purulent material, sections were made and stained according to two methods of Mallery's to determine the presence of any overgrowth of glia tissue. This the specimens examined did not show. The staining was hematoxylin eosin. The wall of the cyst, which was of about 1/32 m. in thickness, shows a very intense small-celled infiltration with an inner layer next the cavity ragged, and in many places broken-down and degenerated; while no typical tubercles were found, there were many rather small suspicious nodular collections of cells which were taken to represent tubercular areas. The outermost area shows a layer of thickening which we think was due to glia proliferation, in spite of the fact that the miliary specimens were negative. There was also meningeal thickening over the area. The cord was not examined as there were no symptoms presenting.

The location of this abscess, tubercular, secondary to pulmonary tuberculosis, explains the aphasia, and also the facial paresis, as it involved the lower half of the frontal region on the left side (speech center) and extended back to the pre-central convolution. The arms and leg centers were not included in its territory. No study of secondary degeneration was made, as the brain was in a state of decomposition when obtained.

METASTATIC ABSCESSES.

Metastatic abscesses are usually pyemic in origin, multiple, and usually not good subjects for diagnostic skill. Bergman says, however, that at times they are solitary and operable. MacEwen says that solitary metastatic abscesses constitute one-third of the pyemic abscesses and Martin found in 22 cases 9 of pyemic metastatic abscesses of the brain. The origin of these metastatic

brain abscesses is usually the lung. Gangrene, abscess, empyema, pleurisy or bronchiectasis, but they may be secondary to gangrene in any part of the body. Like all cerebral emboli the metastatic abscess if solitary is usually found in the left carotid region (Martin's 7 cases out of 9).

SO-CALLED IDIOPATHIC ABSCESSES.

To Bergman's classification of abscesses a fifth group should be added, namely, the group not so much of idiopathic abscesses, but of abscesses in which there has been no previous deposit of pus in the body from which the streptococci could be drawn. This leads us to the discussion of so-called idiopathic abscesses. That there can be no idiopathic abscess in the sense of an absence of some cause for suppuration we must admit. But we know that we can have primary brain abscesses which can not be grouped under any of the four preceding heads. This is an exceedingly important point to remember when we are confronted with the necessity of making a diagnosis or differential diagnosis. Martin has worked up this subject and points out four cases of Strümpell's observed during an epidemic of cerebro-spinal meningitis in which no other cause could be found. Oppenheim says that there is no doubt whatever that the influenza bacillus can cause not only a meningitis or an encephalitis, but that also an abscess may complicate the meningitis, the latter may disappear and the former may remain behind, or the abscess may occur independently of a meningitis. He also reports cases in two articles in which he calls attention to the fact that acute non-purulent cortical encephalitis may simulate brain abscess. At this point I would like to introduce a very interesting case in which the clinical diagnosis was either brain abscess or purulent meningitis.

Case 6.—Lincoln B., aged 38, married. Had deafness and ear trouble since childhood. Pneumonia 10 months ago. Denies syphilis. Has been demented for 3 days (queer actions), brought to hospital in patrol. On admission was maniacal, after 24 hours alternate periods of apathy, depression, with difficulty of speech, alternating with delirium and mania.

Examination.—Pupils equal in size, react to light; slight divergent strabismus; ophthalmic examination negative; can not protrude tongue; responds sluggishly to questions; complains of pain in head; discharge of fetid pus from right ear; extremities weak, rigid with increased reflexes. Babinski's reflex on left side; Kernig's sign well marked; slight trace of albumin in urine; pulse varies from 60 to 70, temperature from 98 to 101.2.

The difficulty of speech increased during the next few days, the stupor became more marked and a twitching of the muscles of right side of face developed; afterward the rigidity with marked twitching but no real convulsions of all four extremities; the pulse going to 130, the temperature to 102.

During next few days some improvement; then developed a convulsion beginning in the right arm and then becoming general. This was followed by coma and death.

The autopsy showed no abscess or purulent meningitis, nor even any congestion, but a marked case of interstitial nephritis.

Here we see how a case of uremia may simulate brain abscess or purulent meningitis. Gussenbauer and Von Beck have published similar cases. Gussenbauer's case was not cleared up at all, Von Beck's proved to be a case of hemorrhage encephalitis of the pons.

SYMPTOMS OF ABSCESS.

The consideration of the symptoms of brain abscess is rendered easier by dividing them into three groups:

1. Symptoms due to deep-seated suppuration.
2. Symptoms due to increased intra-cranial pressure.
3. Focal symptoms.

1. If there is an absence of pus in other parts of the body and there is no other cause, the occurrence of fever with other signs of sepsis may aid us to form a diagnosis. Fever and the attendant signs of sepsis, viz.: general malaise, loss of appetite, headache, occur in remissions and exacerbations, with complete remissions. This variation is dependent upon the successive increase in size of the abscess and is characteristic. The fever in the latent or preactive stage is usually low, rarely over 101, usually between 99 and 100, although in the acute period of active manifestation it reaches a higher mark. Slight chilliness with a rise of fever occurs usually at night. The patients frequently look sickly pale, jaundiced and emaciated. Typical chills may occur in abscess, but repeated chills are rather indicative of septic sinus thrombosis. A high continuous fever speaks rather against abscess and for purulent leptomeningitis, sinus thrombosis or extra-dural pus. The presence of fever in suppurating middle ear or mastoid disease is no indication of abscess.

Bergman and Broca both maintain that the surface temperature is higher on the side of the abscess. The temperature may be normal for a long time during the latent period, and MacEwen called attention first to the frequency of subnormal temperature. In the period of acute manifestation the headache is extremely violent and constant. During the latent period it is intermittent. Characteristic of the headache is its regular increase during the evening fever. This headache may be absent during the rest of the day, is increased by anything that increases the intra-cranial pressure.

In otitic abscesses, and in others also, the pain may be localized over the abscess, and is much increased by percussion. This localized tenderness does not appear when there is inflammation of the mastoid or the neighboring temporal bone in middle-ear trouble. In many cases this circumscribed localized pain and tenderness is very valuable in the localizing of abscesses.

Vomiting is important; early, present in majority of cases, especially cerebellar cases; mere change of position, from reclining to sitting, may bring on vomiting. Vertigo is of little value. The condition of the sensorium varies with the amount of intra-cranial pressure in the latent stage. There may be very little intra-cranial pressure for the reason that unlike brain tumor, abscesses do not compress the brain tissue, but liquefy, destroy and replace it, and therefore large abscesses in a quiescent stage, even to the size of a duck's egg in the frontal lobe, may produce no disturbance of intelligence or of consciousness. In the stage of activity, however, and just before rupture, we have the typical mental hebetude, somnolence, often delirium and hallucinations.

A slow pulse of 60 or less is always indicative of increased cerebral pressure, other causes being absent, but a rapid pulse in the acute stage is often present, and is not a contraindication to abscess. During any fever the pulse usually becomes somewhat more rapid, but in abscess there is often a decline of the pulse rate with increased somnolence during the evening rise of temperature, and this, if found, is a very valuable symptom. Optic neuritis is more frequent than in tumor, but not so well developed (as to degree). If optic neuritis is absent the abscess is either of very acute development or small in size; abscess of frontal lobe has most marked optic neuritis.

Focal symptoms help much to make the diagnosis if the abscess is present in the psycho-motor area, little if

present in the occipital, temporal or frontal lobes. Focal signs in abscess may come and go because of the varying size of the abscess and the disappearance, temporarily at least, of the surrounding softening. We may have large abscesses of the centrum semi-ovale without focal signs, for the pus at first separates the white fibers instead of destroying them, and if the gray matter is intact, a whole lobe, Bergman says the greater part of a hemisphere may be destroyed without the development of a focal sign. The closer, however, the abscess is to gray matter and the greater destruction of tissue the more focal signs are developed. As in brain tumor, we must distinguish between focal signs due to destruction and focal signs due to pressure from edematous infiltration. The latter may come and go; the former are permanent and localizing. As abscesses may be present in any part of the brain we may have any of the corresponding focal signs.

Traumatic abscesses of psycho-motor area are characterized by the rapidity with which monoplegia and hemiplegia follow the Jacksonian epilepsy, or if the abscess is deep-seated, the rapid, but not apoplectic development of a hemiplegia without hemianesthesia. The paralysis is rarely complete.

Abscesses of the frontal lobe, like tumors in this region, have no specially localizing signs; on left side when large we may have motor aphasia involvement of right facial, even of arm; the localizing can be done, however, by considering the causal factors.

The hearing center is of value only if opposite ear is involved externally and has not been the seat of previous inflammation. Hence, according to Barr, it is of no value in two-thirds of the cases because the purulent otitis is bilateral.

Sensory aphasia is present in abscess of the left tempero-sphenoidal lobe. It is very important to remember that in most cases the sensory aphasia is transitory and not permanent; this is due to the fact that the abscess is usually on the underside of the tempero-sphenoidal lobe, which lies above the roof of middle ear, and affects the speech center only by distal pressure. Even epidural abscesses can affect the speech center by pressure (second case).

Abscesses of the temporal lobe are differentiated with difficulty from tumors, because fever is so frequently absent. We must rely on the etiology. Bergman says that even with all our diagnostic aids we frequently make mistakes in temporal abscesses.

With the abscess in the lateral lobes we will usually miss marked cerebellar signs, unless the pressure of the abscess affects the vermiform lobe, when, as in MacEwen's case, we will have marked ataxia. Then the centers and branches of six of the basilar nerves may be affected, but not so often as in tumor. Vertigo may just as well be due to labyrinthine as to cerebellar trouble, and is therefore of little value. Vertigo, uncertain gait and retraction or stiffness of neck are fairly often associated in cerebellar abscess. We can see, therefore, that the diagnosis of cerebellar abscess has usually been made, after the mastoid had been opened. In 19 operated cases tabulated by Koch, 8 times the abscess was found by the finding of a sinus leading to the abscess during mastoid operations, 7 times by aspirating in all directions and finally finding the abscess in the cerebellum, and only 4 times was the diagnosis properly made before the operation by a consideration of signs and symptoms.

A chief factor of chronic latent abscesses is that they are subcortical, usually about one eighth to one-fourth of an inch beneath the surface. The discovery that the cortex of the brain could be punctured and cut into with almost no danger, is very recent. In compound comminuted fractures Ashley Cooper would not even remove the spiculæ of bone which had been driven into the brain. Dupuytren was the first to cut into the brain and empty an abscess, but his patient died, and for many years no surgeon ventured to repeat the daring operation. As a result of aspiration on the one hand and of increased knowledge of the physiology of the cortex on the other, surgeons no longer hesitate to make incisions into and puncture even deep into the brain substance. This procedure, however, is not without some danger. I have seen one death result after aspiration as a result of an injury to a vein of the choroid plexus with hemorrhage into the lateral ventricle.

CONCLUSION.

In conclusion let me introduce Oppenheim's résumé of his diagnostic experience. He says that in the majority of cases of suspected abscess he could rule out abscess at once without any trouble. In 35 cases he had serious difficulties of diagnosis. In 14 of the 35 cases he made the diagnosis of abscess. The other 21 cases were either localized meningitis, cerebrospinal meningitis, encephalitis median otitis and brain concussion.

Of the 14 abscesses, four belong to the period antedating the days of brain operations. In five cases an operation was deemed inadvisable, either because the abscess could not be located or because of complications. In five cases an operation was performed, in two of these the abscess was not found, although present. In the three remaining cases the operation was successful, but only one case recovered, the other two dying of the complicating meningitis. This experience of Oppenheim is the experience of all neurologists and explains the difference of opinion between us and the surgeon. The surgeon sees only the sifted and positive cases and feels that the diagnosis is easy and the results good; the neurologist sees all the doubtful and fatal cases and is not quite so sanguine.

THE DISEASED MIDDLE TURBINATE.*

CHARLES H. BAKER, M.D.
BAY CITY, MICH.

The undue importance which has been given the lower turbinate bodies in the search for the etiology of nasal disorders has overshadowed all other parts of the nasal cavities and led to wrongfully crediting the lower turbinals with the more important instead of the less important rôle in the production of nasal disease. This was principally owing to their easy accessibility and also to the fact that in most nasal disorders these bodies were found swollen and occluding the respiratory passages whereby effect was mistaken for cause.

A moment's reflection will convince one that an acute coryza manifests itself in the region above the lower turbinate first, with a feeling of dryness and pressure followed later by obstruction to respiration due to swelling of the lower turbinate. Very often a patient presents himself with a beginning coryza in which the only perceptible change of the mucous surface is a dryness and redness of the upper nasal chambers with some swelling of the tissue over the middle turbinate and little obstruction to breathing; but a few hours later having the lower passages tightly plugged by swollen tissue.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. Emil Mayer, C. R. Holmes and G. H. Makuen.

The anatomic relations of the middle turbinates are of the highest importance and can not too often be reviewed. The middle, sometimes called the ethmoid turbinate, is the extension of the ethmoid bone into the nasal chambers. This fact must be borne in mind for its important bearing on the etiology of disease in the middle turbinate, for suppurations in the ethmoid cells are often accompanied by a like condition in the turbinate, and vice versa.

Between the body of the middle turbinate and the nasal side wall are the openings of the frontal sinus, maxillary sinus, ethmoid cells, and at its posterior end is the opening of the sphenoid antrum. In a state of health the turbinate acts as a barrier, protecting the outlets of these various cavities from external irritants, but when inflammation occurs the resultant swelling produces occlusion of the outlets and retention of the secretions. The retained discharges ferment and in their turn become irritants, whence the above condition tends to be self-perpetuated.

The shape of the middle turbinate within physiologic limits varies greatly, depending on the type of nasal chambers in which it is found. In the high-roofed narrow chamber it may be merely a thin lamellar plate suspended by its upper border from the inward leaning side wall, and may be easily bent from side to side by the exploring probe. In the wide roomy chambers of the Germanic races it may assume the typical shape described in the text-books, while it may possess almost any variation from these and still retain, physiologically, perfect shape. By this I mean that when, itself not involved in inflammation, it does not press on any of the sensitive areas in its neighborhood or block the openings of the accessory sinuses it may be considered physiologic, however bizarre its shape.

The most common type of the middle turbinate is the one with knobbed anterior, which quite effectually shuts off from view the space lying above and behind. The space between the turbinate and septum varies from 1.5 to 3 mm., and between the turbinate and side wall usually a little less.

The opinion seems gaining ground that the meatuses serve merely as gutters to drain off nasal secretions and when pus is found in them it is produced in one or more of the accessory sinuses or cells. If time proves this to be correct it will greatly simplify our etiology if it does not make treatment any easier.

For the location of the point of origin of nasal pus a certain line of procedure is important. Inspection both anterior and posterior should precede cleansing or blowing the nose and masses of pus will often be seen lying in the lower and middle meatuses which are continued upward to their point of origin, or at least far on the road. After the patient blows his nose inspection is to be made again.

By way of parenthesis let me say that one-half the patients, especially children, need instruction in the proper way to blow the nose, most of them holding both nostrils tightly closed until the air is under pressure, then allowing it to partly escape by both nostrils at once and suddenly checking it; a method eminently calculated to precipitate Eustachian and middle-ear catarrh. The proper method is this: One nostril should be closed by pressure on the ala and the whole explosive air current directed through the open side. When this is properly done the masses of fluid pus will be expelled from the lower passages and inspection will often show the pus drawn out into a rope with one end issuing from the infected sinus infallibly pointing out the way.

Next, a cocain solution is applied with a probe to the lower turbinate and the anterior part of the middle one, sufficiently strong to induce some shrinking of the tissue. This opens the way frequently to discovery of hidden polypi, spurs, etc., which are not seen on first inspection.

Next, with a very thin and flexible probe, the tip surrounded by a thin pledget of cotton tightly wound and dipped in cocain, the regions about the middle turbinate are carefully explored and an estimate of the amount of space between septum and turbinate body, and the latter and side wall is obtained, together with the discovery of small polypi, localized hypertrophies, abnormalities of form and size of the turbinate and possibly denuded areas of bone.

The limited time at my disposal will permit an examination of two conditions only which are the results of suppuration, the one external and the other internal to the turbinate body, both of which may lead to increase in its bulk.

The first of these is nasal polypus, and my first proposition is this: Nasal polypus is a sign of existent or past suppuration in either the ethmoid cells or one of the accessory sinuses. Nasal polypus arises most frequently from the middle turbinate, next from the edges of the hiatus semilunaris around the outlets of the frontal and maxillary sinuses and anterior ethmoid cells, lastly from the posterior ethmoid and sphenoid antrum outlets. They are usually accompanied by suppuration, and I believe they never occur without antecedent suppuration of the ethmoid or the sinuses.

Pus issuing from these and flowing over the mucous membrane, eroded as happens during an acute coryza, excites the formation of true granulation tissue just the same as forms in the suppurating ear or around a healing mastoid and aided by gravity and an over-abundant serous secretion they go on to become polypus. I am aware this is not a generally accepted theory, but it has the merit of newness and plausibility, and in view of the fact that about all authorities acknowledge that the cause of nasal polypus is obscure or "in accord with some unknown law" it is as worthy of acceptance as any.

By far the larger number of cases of nasal polypus, particularly if multiple, will be found accompanied by suppuration, sometimes unseen until the polyps are removed, when an enormous amount of pus may be found to issue from some adjacent sinus. The removal of polypus should be considered as preliminary to more extensive operations in most cases, and should be undertaken only with the cold snare and strong illumination so as to be able, so far as may be, to see every step of the operation. Blind fishing with polypus forceps is a relic from the days of the moxa and seton, and no man is warranted in being guilty of their use.

After removal under cocain and adrenalin of all the polyps in sight, within a day or two it is often possible to find more which have come down from the spaces above, where they had been retained by the pressure of the lower ones, so that several sittings may be necessary to secure those which can be reached without interference with the bone. There is no assurance that when this is done all have been secured, for I have repeatedly removed the middle turbinate body and found from one to a dozen good-sized polyps concealed either behind, above or within the bone. Because of this experience I now make it a rule to remove the middle turbinate, either in whole or in part, when there is active disease of the turbinate, the adjacent sinuses or cells or

when asthma is not relieved permanently or when the polyps reform after removal.

The tendency of polyps to grow again after removal is well recognized, but this is more common with the mucous than the fibrous and the multiple than the single. This is due, not to an inherent disease or degeneration in the mucous membrane so much as it is to irritation from pus flowing over it externally or to purulent inflammation of the underlying bone.

No treatment of the stump is likely to prevent recurrence and is often worse than useless, increasing rather than checking growth. Nothing but removal of the cause will succeed, and to do this the middle turbinate requires amputation. This bone is the site of fully one-half the polyps formed and I believe much more than half, so that its removal gets rid of the basis of the larger part. Then the turbinate is usually greatly increased in size in these cases, adding its own bulk to the causes of obstruction. After polypus has existed for some time, even if from disease of other parts, this bone is found diseased and the pneumatic cells filled with pus or containing polyps.

I would therefore advocate removal of the middle turbinate in all cases of recurrent polypus of the middle turbinal itself; in all cases of recurrent polypus of the hiatus semilunaris; in all cases when removal of polypus opens and reveals collections of pus issuing from the sinuses, and in cases when by pressure the enlarged turbinate causes reflex nervous ailments, such as muscular asthenopia, persistent headache, chorea or epilepsy and especially asthma.

Nasal suppurations, post-nasal dropping, asthma, headache, disposition to frequent coryzas with slight cause; in short, continual nasal irritability is liable to remain so long as a single polypus is left, and if such symptoms persist after the healing following total removal of all which can be discovered, I contend it is the duty of the rhinologist to remove the middle turbinate, or enough of it to uncover the hiatus semilunaris and render easily accessible all portions of the nasal chambers lying above and behind the turbinate. So generally have I found polypus in surprising amounts after such removal in case of multiple polypi that I would now be surprised if I did not find them.

CASE 1.—A case in point is that of a physician, for years an acute sufferer from asthma, who under several eminent rhinologists had run the gamut of fashionable treatment, from galvano-cautery, that converted the nasal chamber into a beautiful dry scar, to trephine, which left only a hypertrophied scar stump on the site of the opposite inferior turbinate. As interlude he had had frequent removals of mucous polypus from either chamber. The right middle turbinate was hypertrophied and pressed on the septum, but no polyps could be detected on either side. To stop pressure the bone was removed and four large polyps were found in the hiatus semilunaris and above the bone posteriorly three additional were found within a week. The result of removing the stump of lower turbinate and straightening a deformed septum on the same side and removal of the middle turbinate of the opposite, with its concealed polyps, was nearly total relief of an asthma which had lasted for years and broken down an otherwise vigorous constitution.

Removal of the turbinate for several different conditions has brought to my notice a considerable number of cases which I think account for the bullous enlargement of the middle turbinate, which is such a fruitful source of nasal disorder. Bullous enlargement has been variously attributed to a periostitis and to a hyperplasia of the bony elements, but these cases point to a very different cause.

CASE 2.—A hay-fever patient had in childhood suffered from eczema and asthma, probably from adenoids, which disappeared before puberty, but his hay fever developed at about 30 years of age. There was at that time no enlargement of the middle turbinate and no asthma, but about six years ago asthma complicated the attacks coincident with commencing enlargement of the turbinate. The asthmatic seizures grew heavier as the bone grew thicker, and lasted later into the winter, until they were likely to be precipitated by any overexertion or error of diet. By this time the bone was pressing continuously on the sensitive septum. To relieve the irritation of this pressure the turbinate was amputated in October last and was found becoming bullous; stiff, inspissated pus occupied the greater part of the cell in the anterior portion. None of the adjoining ethmoid cells or sinuses gave any evidence of disease and healing was very prompt. The patient gained weight and strength very rapidly and passed the last winter in better health than for years. There was very moderate post-nasal discharge with a burning, smarting feeling above the palate, particularly on awakening, and disposition to rasp the throat and an obscure feeling of constant pressure in the bone below the inner angle of the eye, but nothing else to indicate the presence of the pus. There has been no asthma since the operation, but the next hay-fever season will tell whether it is curative for the asthma.

Fig. 1.—Specimens (actual size) illustrating cases 1, 2 and 4. No. 2 is the first case—dried specimen; No. 1, three fragments of specimen from Case 2, also dry; No. 3 is from Case 4, with its adhering polyps P' and P'', the latter being on the upper posterior surface entirely concealed until the bone had been extracted.

CASE 3.—Another case was also an asthmatic without any definite clinical history, either as to origin of the attacks or symptoms aside from frequent severe paroxysms. The removal was done for relief of the pressure on the septum, which was very severe. The bulla, which was very much larger and the walls thinner than in the last case, was found completely filled with cheesy pus. As before, there was no involvement of the adjacent sinuses or cells and the healing was uneventful. There has been no asthma since the operation except an attack brought on by pressure from dry secretions imperfectly removed by the patient.

Case 4.—The last case to which I call your attention shows an extreme development of this condition. The patient was a German farmer, who developed a paralysis of the external rectus of the left eye, for which no cause could be discovered outside the nasal chambers. His previous health had been perfect, there had been no specific disease or any unusual exposure or hardship, no headache, impairment of vision or any discernible cause until inspection of the nasal cavity showed a very much enlarged middle turbinate pressing both on the septum and the side wall, and a large nasal polypus dependent from its anterior end. The polypus was first removed and then the turbinate body, which was filled with thick and cheesy pus. Behind the turbinate was a small polypus which was impossible to discover until the bone had first been removed. No suppuration could be discovered in the adjacent cells or sinuses.

At the time of removal the various specimens of these conditions presented no evidence of inflammation within the cell, the pus being stiff and cheesy, and when the cavity was emptied the lining membrane had the pearly glistening appearance of those in which no pus was found. I therefore contend that bullous hypertrophy, the so-called pneumatic distention, is the result of continued suppuration within the middle turbinate, doubtless from infection of one of the normal pneumatic cells, and that the growing accumulation of

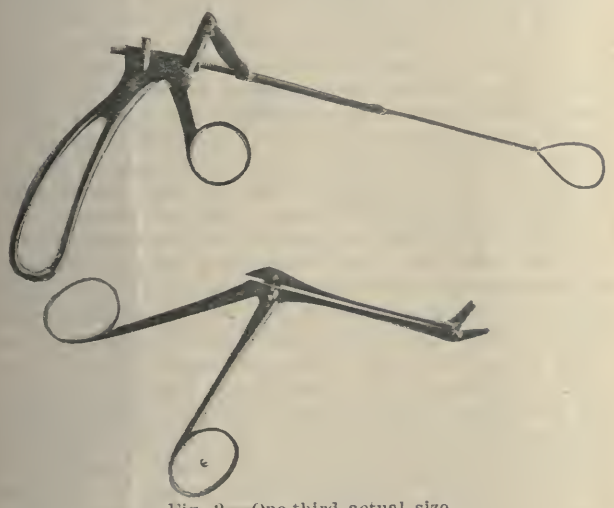

Fig. 2.—One-third actual size.

pus causes the obscure feeling of pressure of which patients with fairly open lower meatuses often complain.

Internal pressure fuses the existent pneumatic cells and gradually distends the bone, at the same time thinning the wall of the cell. The suppurative process in time dies out, the pus is absorbed and the cell is empty, or it may contain one or more polypi which in no way differ in appearance or origin from the mucous polyp of the other parts of the nose.

In conclusion let me say, the removal of the middle turbinate is not always the easy operation it is when the bone is thin and dependent. Its base is often wide and the bone dense and a variety of instruments are required. Various modifications of Grünwald scissors and forceps and a good snare are necessary, and they must be mechanically correct or they will fail to work at a critical period.

I wish to call attention to a modified cutting forceps with angular blade which I have found useful, particularly in cleaning the ethmoid cells and edge of the hiatus semilunaris.

The snare, which is operated by a toggle joint, operates by pushing the canula over the loop instead of drawing the latter into the canula, which makes it easy to remove sessile growths and it is particularly suited to remove posterior hypertrophies of the turbinals, which are usually so exasperatingly elusive. This snare will cut the turbinals very easily, and as it threads the loop like the Sajous snare it is very quickly made ready and very economically of wire.

I have been asked if the removal of the middle turbinate does not unduly expose the sinus openings to external irritants in the inspired air currents. It does not, and for the very good reason that the bulk of the air current does not pass into the upper chamber, as we have been taught.

All experimenters, so far as I have been able to learn, who sought to determine the direction taken by the inspired air in its passage through the nose, have blown the air through the nostril to the pharynx instead of drawing it through, as is the method of Nature. The result has been identical with the act of pushing a string through a hole, namely, to bend it in all sorts of directions instead of pulling it through, in which case it goes straight. The only correct way would be to attach a suction apparatus to the posterior naris and draw the air through, in which case the course would be in the line of least resistance, which would be by way of the lower meatus.

DISCUSSION.

Dr. O. T. Freer, Chicago—Where the nasal fossa is of a high, narrow construction or is contracted by reason of a moderate septal deflection I have found that there is at times not sufficient room for the manipulations with scissors or cutting forceps necessary for the removal of the middle turbinated body, unless force be used in applying the instruments. In these cases I have successfully employed a heart-shaped spokeshave with the blade attached to the shank at an angle of 45 degrees. The blade is passed back into the nasopharynx and applied to fit over the posterior end of the middle turbinated body. Then, with a strong, steady pull forward, while the shank of the instrument is crowded upward and uplifts the cartilaginous external nose, the middle turbinal is cut away. Where possible it is well to sever the anterior attachment of the middle turbinal with scissors as a preliminary, as scissors can usually be applied here, even though there may be no room to use them further back. Lifting the external nose makes it possible to bring the spokeshave forward in nearly a horizontal line. The method seems crude, but really does with one clean cut what is accomplished by many with scissors, cutting forceps and snare. Where there is room for the latter instruments their accuracy of application makes them preferable.

I think that Dr. Baker has exaggerated the influence of intranasal suppuration in producing nasal mucous polypi. I think that we have all seen cases in which, before and after removal of polypi, there was no evidence of suppuration, and I think that in the majority of instances there is no purulent discharge visible in the nose. I can recall two cases of cyst of the anterior end of the middle turbinal, neither of which showed proof that there had even been any suppuration, and I think that simple cyst of the middle turbinal is rather more common than the suppurating cyst.

Dr. Edwin Pynchon, Chicago—There is no doubt that nasal occlusion in child life is one of the most frequent causes of the coryzas and catarrhs we so often meet in years later. Suitable attacks on the hypertrophied middle turbinal will give drainage to the attic of the nose. The course of respiration has been proved to be normally through the upper part of the nose, hence, as soon as the upper part of the nose is stopped, the normal respiration is interfered with, so we get our catarrhal manifestations. As regards blowing the nose, I have been in the habit of instructing patients to stoop over the washstand and blow simultaneously through both nostrils, preliminary to the cleansing of one nostril after the other. The enlargement of the middle turbinal and the pressure resulting therefrom is a common cause of headache.

Asthma and hay fever are particularly aggravated by attic occlusion from middle turbinal enlargement. There is one point that I have been rather surprised not to find mentioned in the literature, and that is the invariable association of middle turbinal hypertrophy with atrophy of the inferior turbinal. I have found the best results in atrophic rhinitis to follow vigorous attacks on the middle turbinal so as to improve the ventilation and drainage of the attic of the nose. One very important thing in operating is not to substitute one evil for another, therefore we do not want to produce a synechia which will also cause occlusion. Consequently, a method of operation should be selected whereby the wound will be limited to the middle turbinal and whereby the mucous membrane of the septum will not be injured. The objection to the punching forceps, often used, is that the mucous membrane of the septum may be injured and a synechia follow. I have designed a trephine, whereby I can remove a piece from the anterior end of the middle turbinal both painlessly and bloodlessly. This trephine is different from the ordinary trephines and is very much longer. It is probably six inches long, including the hand-piece collar, and the projecting guard is perhaps an inch and a half long and projects about one-quarter of an inch beyond the trephine, being thin and flat, so it can always be passed between the middle turbinal and the septum, and thus serves as a protector of the mucous membrane of the septum. As the trephine enters, the guard projecting beyond its point acts not only as a guide but also as a guard, preventing the injury of any part that it is not desired to touch. By a slight up and down motion the core is detached and the trephine removed, leaving a hole in the turbinal into which one blade of a pair of shears may be introduced while the other blade is placed in the meatus beneath and an incision is then easily made with the shears. This leaves a loose piece, somewhat resembling a polypus that is horizontal instead of vertical, about which a cold snare is introduced, so the entire piece is removed. I will say I have found that there is more resilience in a certain kind of wire that is sold as the E guitar string wire. In regard to the snare, I have found the Bucklin snare to be the most satisfactory. It is a modification of the Wright snare. I have not seen the forceps mentioned by the essayist, but it has occurred to me if the blade that cuts upward was only a fenestrated blade, as in Dr. Myles' forceps, it would be more useful. I recently ordered such a pair from Europe, but when the order returned the forceps were not included. I have since learned that such forceps have been designed by Dr. Roe of Rochester, but I have not yet been able to secure a pair.

DR. G. V. WOOLEN, Indianapolis—I have noticed of late a very strong tendency to deal with the affections of the nose and head with a view to suppuration and empyema. One time we ran in the direction of microbes, and then we ran in the direction of suppuration. I have not heard anything about pressure irritation. I wonder if we have forgotten the classical paper by Dr. Lefferts, written in the eighties, in which he called attention to pressure irritation and defective drainage. When we take into consideration the nasal nerve coming down over the turbinates and septum, the form of the attic of the nose and the middle turbinal, the first thing, it seems to me, that we ought to think of is pressure irritation. Anybody who has had an attack of pain from a corn or bunion can appreciate it.

DR. KATE W. BALDWIN, Philadelphia—I have had one case of severe hemorrhage seven days after a turbinectomy. At the time of the operation a number of polypi were thoroughly removed, leaving the space free. There was almost no hemorrhage at the time of the operation and not until the seventh day, when it occurred after some vigorous exercise. It was as alarming a hemorrhage as I have seen in nose and throat work. There was so little bleeding at the time of the operation that I did not pack. At the time of the hemorrhage I was obliged to do so. A large polypus had come down, and I am not sure whether or not it was the release of it that caused the hemorrhage.

DR. EMIL MAYER—What was the age of the patient? Was there any constitutional condition, hemorrhagic diathesis, that might account for it, or might there have been an arteriosclerosis?

DR. BALDWIN—The patient's condition was very poor, especially the mental condition. I think there were probably polypi in the sinuses, but I had no further opportunity to watch her. There was no hemorrhagic diathesis. The mental condition improved somewhat. The patient was 25 years of age.

DR. MAYER—The reason I asked the question was to determine if there was any arteriosclerosis, such as might be due to syphilis or something of that kind.

DR. ALLEN DEVILBISS, Toledo, Ohio—I wish to ask a question of Dr. Baker. I understood that he would hook his spokeshave over the growth and pass it through the mucous membrane and bone at one pull. Is that correct?

DR. BAKER—Yes, sir.

DR. DEVILBISS—I believe I have a good strong hand, but I can furnish some turbinates in which the Doctor would have to have a stronger arm than I have to do that. We could shave the soft tissues off in that manner, but it requires only a little resistance to stop a cutting edge against a hard surface. It is different if you can use a sliding motion, and it may be that the Doctor has some peculiar method of doing this.

DR. O. T. FREER, Chicago—I have resected both the inferior and middle turbinated bodies in this manner and have had no trouble in cutting through the bone in the cases that I have so far met. Ordinarily the turbinated bones are so frail and porous that they can be infracted with the finger and they offer thus but little resistance to the strong edge of the spokeshave. Where middle turbinectomy is done to give drainage of the upper nasal passages, the middle turbinated bone is often softened by rarifying osteitis, due to chronic suppurative inflammation. There is less trouble in cutting through the bone than in hooking the spokeshave over the posterior end of the turbinated body. This may be impossible of performance and the instrument may slip off, where tortuous nasal chambers displace it from the intended direction. I do not advocate the use of the spokeshave as an exclusive method for turbinectomy, but as a valuable resource where scissors, snare or cutting forceps can not be employed with satisfaction. In these cases it may do with one cut what otherwise could only be attained by tedious and painful manipulation.

DR. R. C. MYLES, New York City—I must confess it has been rather difficult for me to always tell definitely how far the middle turbinate is diseased. We have mechanical conditions that interfere with its functions and when those are relieved the middle turbinate recovers. That is chiefly true in cases of deflection of the septum. If the deflected septum is properly treated, the middle turbinate will return to its normal condition. Removal of the anterior half of the middle turbinal will relieve many cases of incipient empyema. Eight or ten years ago I described an instrument in the *Medical Record*, and from that time until now I have modified it, until I believe in all cases in which the septum is not deflected, and in many cases in which it is, it may be moved over sufficiently to introduce this instrument. Under cocain and adrenalin the turbinal may be quickly and satisfactorily removed. I was forcibly struck by the elongation of the uvula in cases of quinzy. It may become three or four times its normal length within a few days. This is because the quinzy interferes with the venous return of blood. I have found that elongated palates, more or less chronic, may shorten up when the blood is allowed to return through the venous channels. I believe much is due to the stasis of blood circulation. We find it in arteriosclerosis, and in syphilis and in polypi. When the antrum of Highmore is opened and free ventilation is secured one will find that polypi and edema will frequently disappear, because the pressure has been removed and the irritating material drained off.

DR. P. J. GIBBONS, Syracuse, N. Y.—In the removal of the middle turbinate, I have often found we can make a mere perforation, if necessary, and it will make a cracking sound as if you punctured the shell of an egg, and then you can use the instruments more readily. I have seen the anterior portion of the middle turbinate so dense that the electric

drill, revolving 2,200 to even 3,200 revolutions per minute, would not touch it. I would like to speak of the total removal of the middle turbinated bone. You should not remove it entirely except when you can not possibly help it. The posterior part, if possible, should be retained. If the turbinate presses on the septum, crush it, if necessary, as you do in craniotomy for the removal of a child. An article by me appeared in the *New York Medical Journal* of July 9, 1892, on the treatment of nasal stenosis by means of a new intranasal tube. I called it a new intranasal tube because Hippocrates and later Galen used intranasal tubes. Dr. Baker called attention to asthma. In one part of my article I say: "In the tube we possess a valuable device, and with it, in conjunction with medicinal and operative treatment, we can cure diseases that we were unable to cure in the past. This is true, especially in asthma and hay fever, which, I believe, can positively be cured by one or more of the drugs which we now possess, or by operative interference, or by using the tube, or it may be necessary to resort to two or even the three measures combined to cure some of the cases we meet."

I think the opening of the anterior part, either with the drill and the removal of part of it afterward, or by some other method, is better than the total removal of the middle turbinate. If you ever want to make a new instrument for nose and throat work and want to know whether there is any like it made, it has been said that all you need to do is to write to Dr. John Roe, and you will probably find that he has made the same thing a number of years before.

Dr. W. S. Anderson, Detroit—I want to make a plea not to destroy more than is absolutely necessary in the removal of the turbinals. Only in a very few instances is it necessary to remove more than the anterior portion. It is possible, in many cases, to make an incision with a small knife through the mucous membrane, push it up, remove the anterior portion of the turbinal, drop down the flap of mucous membrane over it, and thus save the mucous membrane. There is too much of a tendency to unnecessarily destroy tissue. By being careful one can often save the mucous membrane, which is so often destroyed. The results, after the saving of the mucous membrane, are more satisfactory and prompt and the irritable scars are largely avoided.

Dr. J. A. Stucky, Lexington—I wish to protest against the crushing process for the removal of the turbinal. I have frequently found an osteitis following the use of this method. I would like to refer to the use of Dr. Holmes' little scissors. With them you can cut off an enlargement with a single cut while you would be adjusting a snare, and in this way take off two turbinates while adjusting the wire around one.

Dr. George L. Richards, Fall River, Mass.—I think an examination of the skulls here will show the portion necessary to be removed is the anterior portion, and if you use the spokeshave that is practically all you can remove. That is the operation I almost invariably do, only I do not do it with the spokeshave, for the removal of the anterior third is usually all that is necessary. Beside, I think a part of the middle turbinated is important in olfaction.

Dr. B. A. Randall, Philadelphia—The essential basis of much of this work depends on the question of how we breathe and what is the respiratory tract of the nose. It is remarkable that such a matter should still be a matter of dispute. The failure definitely and finally to answer this seems to depend largely on the work of such men as Harrison Allen, who made very few mistakes, but who, because of study of comparative anatomy and the anatomy of the lower animals, was led to believe that we have an olfactory tract above and a respiratory tract below. Dr. Baker seems to take the same view. If you will take a few grains of magnesium powder and dust it in the air before the patient with normal, tidal breathing, and then find any of it, as drawn in and deposited on the mucous surfaces, below the level of the middle turbinate you will very much surprise me. The lower nasal meatus is not the respiratory but the drainage channel. You can, in this manner, very easily convince yourself that the upper olfactory tract is the respiratory tract of the nose. It is a pity that the matter is not clear in the minds of every one. Dr. Baker's admirable ecraseur observes the only proper indication in that the cannula moves forward over the snare. I mention this because others may have only the other kind of snare, such as the Jarvis, and will find that it will slip off if the loop is drawn. But it is perfectly feasible for us to push forward the cannula over the snare, when we use any of those snares, and avoid all slipping.

Dr. C. R. Holmes, Cincinnati—I have made a crude sketch here. Some of you have probably read my article on the removal of the turbinated bodies, particularly the inferior turbinated, and in that is pictured also the manner in which the scissors are introduced. And, by the way, I wish to state that they are usually not made correctly. Meyrowitz does make them right, but I have seen some not made correctly. If they are too long they will fracture. I have had Meyrowitz thicken the point a little and strengthen it so that they answer better. I have had occasion to see how a little lack of knowledge in the use of an instrument may cause the condemnation of the instrument. I let my first assistant remove a turbinate. He is an able man, who has been with me for three years. I noticed him having some difficulty, and finally he said: "Doctor, that is too hard; we can not cut it." I found he had taken the middle turbinate in the middle of its body. The object of the scissors is to get up near to the wall, and that is the reason they are made in this shape. A pair of scissors has been made by another gentleman, that work at right angles, but they do not seem to me so applicable. By taking hold of it with a pair of forceps, after using the scissors, or, if necessary, following the scissors with the snare, we can readily remove the turbinate. Many a man, however, does excellent work with a clumsy instrument, because he is familiar with it. I would say it is advisable to buy the smaller size of these scissors, because they usually are sufficient. Dr. Randall has called attention to the fact that the air does rise and go through the upper passages. The air passes along the upper passages of the nose, and if you have obstruction there you must remove it. At the time my paper was written I had made 1,500 turbinectomies, and I have made 2,000 since then, but they were not all middle turbinectomies by any means.

Dr. Emil Mayer—I would like Dr. Holmes to make it a little clearer that two instruments are used, a right and left, and that the instrument is suitable for the middle turbinated but not for the inferior turbinated.

Dr. Holmes—Yes, that is true. For the removal of the inferior turbinated I prefer an instrument made by Betz.

Dr. G. Hudson Makuen, Philadelphia—When you are standing, the air passes naturally upward, and it would have to go almost at a right angle to get through the inferior passage of the nose. I have accepted Dr. Reynolds' explanation without having tried the experiment, for it seems to me that is the natural course for the air to take.

Dr. Holmes—Those who are interested in that subject will find that the experiment has been made. Cadavers were used and the inside of the nasal passages painted with iodin and powders of starch were used, with the cadavers in both the standing and sitting position.

Dr. G. McAuliffe, New York City—The inspiratory currents experiment, etc., quoted by Dr. Randall were mentioned in a French magazine some 8 years ago. Since then I have been interested in studying the middle turbinate. It is surprising how often we will find collapsed inferior turbinates with troubled respiration due to the encroaching middle turbinate. We then find it is usually the turgescence of the mucous membrane which it is necessary to treat. By snipping off the mucous membrane of the anterior end of the middle turbinate, we can relieve the symptoms of impaired respiration. The statement of Dr. Randall that the powder is not found on the inferior turbinate will be explained by the fact that the air enters the nose in eddies. The eddies started up by the slow inspiration carry the powder to the roof. There is no doubt that some of the air passes across the surface of the inferior turbinate. The quick expiration goes more through the inferior meatus. All the treatments that have

done any good have been those in which the space of the middle meatus has been enlarged. By enlarging the space in the middle meatus we relieve the stagnation of secretion and the difficulty of inspiration that these patients complain of.

Dr. J. C. Beck, Chicago—Two points I would like to make. In regard to the enlargement of the middle turbinate, nothing has been said about the effect of a large middle turbinated on the tear duct. After turbinectomy, you will find it stated that secondary hemorrhages, due to infection, may occur, where the proper cleansing of the nose is not attended to after operation. This is hemorrhage due to infection.

Dr. Ira J. Dunn, Erie, Pa.—It seems to me appropriate to present these scissors, which I have found more satisfactory in nasal operating than any I have been able to find in the stock of the instrument makers. It was only after thorough search and failure to obtain scissors that would cut on the point strong enough to go through bone if necessary and still leave room for observation that these were devised. They only represent the best ideas of others. They are very strong, the blades are straight and compact, giving all possible room for observation. The hand is well out of the way of vision and situated so that, if necessary, a powerful grasp can be made. The edges are serrated, so that they do not slip back, but go cleanly through any tissue, cutting by one closure what is with difficulty accomplished by other scissors by a number of cuts. With more or less blood present, as is usual, several

cuts necessitate making a ragged and bruised surface. They enable one to cut off the posterior portion of a turbinated which otherwise usually has to be snared, because they do cut clear to the point. I hope they may be found useful by some of the members of the Section.

Dr. Charles H. Baker, Bay City, Mich.—I purposely omitted the method of removing the turbinal, because I described that at length in my paper, read last year, in which I credited Dr. Holmes' instruments. Dr. Holmes has said that the base is not always of a thin lamellar character, and sometimes the scissors may be used with difficulty. In those cases I have found the Gruenwald instruments and, particularly, the angular one which I have devised, very useful. I frequently find it advisable to remove the whole body of the turbinal. The polypi often occupy the posterior upper portion of the middle turbinal and you can not see them until you have removed the bone. That will explain the frequent failure to cure nasal polypi by persistent removal. I will acknowledge that I have sometimes secured the cure of polypi in this way. Failure is due to the polypi sometimes being out of sight, in the way I have described. Anatomically, the tear duct has no relation with the middle turbinate, since it opens behind the lower turbinate. As to synechia, they occur when you have not removed sufficient tissue or can not keep the patient under observation long enough to know that healing is complete before he passes out of your care. The trouble with the spokeshave is that you are trying to remove a curve by cutting on a straight line, and you often will not remove the entire body if you use the spokeshave.

Age Limit Fixed by Dentists.—In the November *Digest* we stated that factory inspectors in Illinois were enlisting the aid of dentists to tell by the teeth the age of children who seemed too young to work in factories. There is now a bill before the Illinois legislature providing that no factory owner shall employ a child who can not produce a certificate from a dentist showing that he is over 16 years of age.—*Dental Digest.*

TYPHOID FEVER WITH PERFORATION OF THE BOWEL AND RECOVERY.

T. K. HOLMES, M.D.
CHATHAM, ONTARIO.

Miss S., aged 30, of good family and personal history, was attacked with typhoid fever Oct. 6, 1900, and the disease pursued a mild and favorable course until October 26, when she was seized with agonizing pain in the abdomen accompanied by severe shock. I saw her half an hour later and found her temperature 96, pulse 150, skin cold and wet and altogether presenting the symptoms of perforation. The nurse had given a hypodermic injection of morphin ¼ grain, and strychnin 1/20 grain. Dr. J. H. Duncan saw the patient with me and we deemed it inexpedient to operate on account of her desperate condition. The strychnin and morphin were repeated at varying intervals to control the pain and sustain the heart, and normal salt solution was transfused beneath the skin every 12 hours, a quart being used each time. Tympanitis, which had been absent, soon became excessive, and vomiting was almost

Pelvic abscess due to perforation of a typhoid ulcer. A transverse section of the body just above the pelvic brim. Small portions of the bladder, uterus and of the left tube and ovary are seen, but the major portion of the pelvis is occupied by a large abscess. The intestinal loops are everywhere densely adherent to it and at the point indicated by the arrow is an opening between the loop of the small gut and the abscess. The omentum also was adherent to the surface of the abscess.

incessant for 24 hours. For ten days the patient was sustained entirely by rectal enemata. On the tenth day the bowels moved spontaneously, the bloating subsided and the stomach became tolerant of small quantities of peptonized milk.

Recovery after this occurred gradually, but when the bloating and tenderness had sufficiently subsided to permit examination a hard mass could be felt below and a little to the left of the navel, and could also be detected by pressing the finger through the vagina in the same locality. The mass was very hard and no fluctuation could be detected at any time. During the winter she gained slowly in strength, but her pulse never became normal and there was a slight rise of temperature toward evening.

In April, 1901, I consulted Dr. Cullen of Baltimore as to the propriety of operating on the patient, and asked him to perform the operation. This he did May 9, assisted by Dr. McKeough and myself. On vaginal examination a distinct mass could be felt occupying the pelvis, but not lying very low. On making an abdominal incision the intestinal loops were found adherent to the surface of this mass, which almost completely filled the pelvis. They were separated with considerable difficulty. In liberating one of these adhesions, evidently at the point of rupture, a perforation fully 2 cm. in diameter was found blending with the wall of the sac. This opening was closed with a continuous silk suture and reinforced by a second one. Further intestinal loops were freed, but it was impossible to remove the sac. The sac was punctured and about 700 c.c.

of most fetid yellowish white pus escaped. This had the characteristic fecal odor. The sac was scoured with gauze and a thick layer of granulation tissue removed from its walls. During this procedure the intestines were walled off carefully and after operation the intestinal fat was drawn up to and fastened to the upper part of the incision to prevent the intestines from dropping into the pelvis. A light iodoform pack was introduced around the sac and a loose drain placed in its interior.

The patient stood the operation well and in the evening the pulse was 116. The gauze packing was removed on the third day and the drain continued to be replaced daily until only a small sinus 3 inches deep remained. The hardness to be felt per vaginum did not completely disappear and much pain and tenderness remained at the left side of the cervix where the hardness was most marked.

A month after the operation this hardness had emptied itself into the sinus and a free discharge of pus was followed by freedom from pain and tenderness and fever. It was possible now to introduce a small glass irrigation tube through the sinus from the abdomen a distance of 5 inches downward and toward the left, and in this way the second abscess cavity was irrigated daily for several weeks, but drainage was so imperfect that I decided to make a counter opening into the vagina. I was thus enabled to pass a perforated rubber drainage tube from the abdominal surface through into the vagina and in this way to get better drainage and to irrigate the whole canal. By gradually withdrawing the tube the sinus finally closed and there was no further trouble. The patient has fully recovered her strength.

Special Article.

THE TYPHOID EPIDEMIC AT ITHACA.

(By Our Special Commissioner.)

I.

Ithaca, N. Y., March 10, 1903.

Ithaca is a town of about 13,000 inhabitants, with an additional student population of some 2,500. An excessive number of typhoid fever cases began to appear about Jan. 15, 1903, but it was not generally recognized that there was any unusual prevalence of the disease until Monday, January 26, when one of the local papers contained a statement that 73 residents of Ithaca were ill with "fever." During the week of January 26 to February 1 the epidemic progressed rapidly, and on February 2 it was stated that 237 cases of the fever existed in the city.

Up to the present date there have been about 91 cases among the resident students of Cornell University, and 12 of these have resulted fatally. There have been 8 additional deaths among Cornell students who had gone to their homes outside of the city; and it seems not unlikely that altogether 150 cases have thus far appeared among the student body. It is, at present, impossible to obtain exact information regarding the number of cases that has developed in the whole city. The number of deaths among the townspeople amounts to at least 24, and up to the present time more than 600 cases have probably occurred. The crest of the epidemic seems to have been reached in the latter part of February. Since the first of March the new cases reported have been relatively fewer in number and are of a much milder type.

The public water supply is distinctly responsible for the outbreak. Those portions of the town receiving any of the water from Six Mile creek have suffered most severely, while the houses on the University campus and in its immediate neighborhood, including Sage College, with its 200 women students, in all constituting a population of more than 500, have been practically exempt. The one exception is a student who is known to have taken water in the infected part of the city.

It has been known for years that the public water supply was impure and wholly unfit for drinking purposes, and the present epidemic is the outcome of conditions which were clearly understood and the significance of which was urged on the authorities many times.

During the last week a material improvement in the situation has been effected by the energetic action of Dr. Soper, representative of the New York State Board of Health. Measures designed to diminish the opportunities for secondary infection have been vigorously pushed under his direction, and it seems likely that the persistent application of rational methods will speedily relieve the local tension and restore complete confidence to the stricken town. So much infectious material, however, still exists in and about the community that rigorous precautions will have to be continued for a long time to prevent a recurrence of the same epidemic conditions.

Much enthusiasm has been manifested locally in a project for obtaining water for the entire city from artesian wells sunk in the valley, but it is stated by high engineering authority that an adequate and satisfactory supply is hardly likely to be obtained from this source. Measures for improving the character of the present supply by rigorous control of the water-shed or filtration are also being considered. The university authorities have already placed a contract for the installation of a small mechanical filter to supply the university campus. It is expected that the filter will be in operation within 35 days. The present university supply (from Fall Creek), as has been pointed out, is not involved in the present epidemic, but is nevertheless liable to sources of gross pollution. Good fortune rather than good management has been responsible for the immunity of the district served by the supply, since the conditions of the water-shed do not differ materially from those of the basin of Six Mile Creek.

(To be continued.)

Smallpox Vesicles.—A writer in the *Lancet*, referring to the prevalence of smallpox in London, and the difficulty sometimes in mild cases of differentiating between this disease and chickenpox, calls attention to a well-known method by which the object can be attained. The vesicles in chickenpox are unilocular, while in smallpox they are multilocular, the practical result of this pathologic fact being that, if a chickenpox vesicle be pricked with a needle, its contents can be completely evacuated, and the cell will collapse; whereas in smallpox, if you make twenty pricks with a needle, the vesicle will not collapse, because, being multilocular, it is impossible to empty it. —*Medical Times.*

FAMILY CARE OF THE INSANE.

In the proceedings of the Twenty-ninth National Conference of Charities which has just appeared, there is an article on a system for the care of the insane so little known to Americans as to merit attention. It is written by Julia C. Lathrop, for some years a member of the Illinois State Board of Charities, who has personally observed this system in Scotland, France and Belgium. Briefly stated, this system consists of family care for certain classes of quiet patients.

The village of Gheel in Belgium is the classic instance of such care. Here for more than a thousand years patients have been received into the homes of the villagers as boarders, and at the present time the boarding of 2000 patients is the main industry in the commune with its 6000 inhabitants. About twenty years ago a similar colony for quiet patients was opened by the government at Lierneux in southern Belgium. This has prospered and now contains between 400 and 500 patients. In 1892 the French government began the care of women patients in the village of Dun-sur-Auron and in 1900 they began at Ainay a like undertaking for men. These colonies were only opened after the French had studied what is known as the Berlin system as well as the Scotch and Belgium methods. By the Berlin system patients are sent out from the asylums, as Dalldorf, to board in neighboring families under the medical supervision of the asylum physicians, and it is chiefly valued as a halfway home for convalescents, while the French, Belgian and Scotch systems apply primarily to chronic patients and offer a method of permanent care.

In 1900 there were 654 women patients at Dun-sur-Auron and Ainay was just opened; in 1901 Ainay had 100 men. The patients have the greatest possible measure of liberty. If they desire, they do work of various kinds according to their former occupations; but it is expressly understood that their labor does not belong to the families in which they live and that they can dispose of their time as they like. A medical superintendent is in charge of each colony and effective supervision is easy because the patients are so concentrated. In Scotland, family care has a still different development. Instead of gathering patients into large village groups, they are carefully scattered so that there shall not be enough in any one place to give it a distinctive character. In 1901 there were 2793 patients in private dwellings in Scotland, while the total number of insane was 15,899. It is evident that family care is not suitable for all classes of patients, but the experience of Scotland and Belgium shows that in both of those countries about 20 per cent. of all the insane may be thus cared for.

The principal arguments in favor of the system are: 1. Humanitarian. The increased comfort and happiness of patients. A Scotch inspector says: "The freedom from irksome discipline and the social advantage of mixing with sane people of their own rank in life and on a footing of equality, has a wonderfully beneficial effect and has resulted in not a few cases of complete recovery." The Belgian and French authorities tell the same story. 2. Economy. The daily expenditure per capita in asylums of the Department of the Seine is 58 cents. At the village of Dun it is 28 cents. "In Scotland the current cost of boarding-out is about two-thirds that of hospital care," and this estimate does not take into consideration the enormous cost of hospital plants.

The most obvious objection to this system would be the danger of violence to the families, yet Drs. Peters and Duperon in Belgium, Marie and Lwollf in France, agree in stating that instances of violence are of phenomenally rare occurrence, while in Scotland it is authoritatively stated that "during the 43 years in which this system has been in operation there has been but one serious assault committed by a boarded-out patient"—a record of amiability scarcely to be equaled by a like body of sane boarders for the same period, were the truth known.

Miss Lathrop gives an instance of family care in Scotland and draws a contrast between it and the American system. In the course of a visit to one of the Scotch villages, she found a male patient sitting in the cottage of one of the neighbors tending a baby, and was told that this baby was the object of John's devoted care. "Not long after, I was visiting an American asylum of the usual baronial castle type and in a locked ward of rather violent patients an elderly woman was knitting a pair of socks. The attendant said she could live perfectly well outside 'if she only had some one to look after her a bit.' In the main building a few hundred feet distant, apparently, but really as remote as Europe, she had heard that there was a new baby in the family of one of the staff physicians, and sent a pair of socks of her own knitting to this child whom, probably, she would never see. She was far more expensively housed, clothed and fed than John; the great building in which she lived was set in the midst of a splendid park instead of a humble cottage garden, but as for me or any kin I would choose the lot of John."

THE LIMITATIONS OF THE CYTOTOXIC THEORY.

Just now the cytotoxin occupies the center plank of the stage of medical research. The antitoxin is ancient history, and even the hemolysin and the bacteriolysin are falling behind. There is probably no organ or tissue that is not now being injected in emulsionized form into the midst of the complacent goat, the sedate goose, the

rabbit or guinea-pig. We may look soon for a deluge of reports on cytotoxin work, and we should await them with interest, for present indications are that the results may be either very great or very small. It is the simplicity of method that undoubtedly accounts for the rapid and general invasion of the field. One simply takes some particular organ or tissue, preferably one not already studied, grinds it up with sand and aseptic precautions, extracts it with salt solution, and injects the product into the selected animal. After a number of such injections at intervals of a few days the injected animal is bled, the serum separated from the corpuscles and injected into an animal of the same species as those that have furnished the tissues; and then the last animal is studied, both alive and dead, for evidences of effects of the serum.

The earlier reports that have been published have not been harmonious, and it is hard to know what to expect; but because of the large number of workers we may reasonably anticipate that it will not be long before enough facts have been established to set the work on a firmer basis. That it is an enticing study there can be no doubt, and from the standpoint of science it should be worked out to the end. How much is to be expected in a practical way is another matter, and it may be well for the benefit of those who are not in a position to appreciate the exact situation to call attention to some of the obstacles that may prevent practical application, in order that too great expectations may not arise. The first is the fact that to a large extent results are being obtained with heterolysins rather than with autolysins. By this is meant, for example, that in experiments on neurotoxic serum a goose is immunized with nervous tissue from dogs, and that its serum is then injected into dogs to study its effects. It is evident that the conditions so established are not the same as with serum obtained from dogs treated with dogs' tissues. And even in the latter case there is still a gap before we reach ordinary conditions of human pathologic processes, in which the toxins, if produced at all, would arise within the body of the animal they affect. As might be expected, the general rule is that the more remote in nature the two kinds of animals are the more activity will the cytotoxic serum possess; therefore, experiments using animals of the same species have yielded little result. It is evident that as matters now stand we can not apply many of the results obtained with heterogeneous serums in explaining the genesis of pathologic processes, for these must, if due to cytotoxins produced by cell immunization, be due to cytotoxins produced within the body of the very animal that they attack. However, there is some hope in this direction, for a few studies of autocytolysis have indicated that it may occur; these have concerned particularly the kidneys.

The earliest work, in which destruction of such cells as ciliated epithelium was observed, suggested the possibility that an immune serum against cancer might be produced, and attempts have been made in this direction. Here one great obstacle lies in the difficulty of securing material with which to immunize the animals that are to furnish the serum. To treat a single case of cancer of the breast, for example, would require the amputation of many other cancers of the breast to secure material for immunization. Furthermore, when we come to consider cancers in sites where they are generally badly infected, as the stomach or uterus, we should undoubtedly find difficulty when we inject our animals. Another therapeutic possibility lies in the anticytotoxic serum, which is obtained by immunizing animals to the cytotoxic serum. Here again the application to human medicine is impossible, for where are we to find subjects which will produce our anticytotoxic serum, even if we were able to procure human material to immunize animals in the first place?

Our only object in making prominent these difficulties in the practical application of this particular line of work is to caution against the evident tendency of those who are not fully informed to draw unwarranted conclusions or predictions. There is probably no investigator who does not appreciate the situation fully. Undoubtedly there are possibilities that means may be found to evade the obstacles, and great advances result. But even were there no hope evident that any clinical use might come of all this work it is the right of science to expect the study to be pushed to completion, if for no other reason than that there are questions still unanswered. We have never the right to ask of science, *cui bona?*

A NURSES' STRIKE.

The trained nurses in a New York hospital recently struck and left the institution badly in confusion for a time. By aid from other hospitals the trouble was tided over without serious consequences, but the occurrence is an unfortunate one and does not tend to elevate the opinion of the profession as regards the strikers. The affair curiously paralleled certain labor union strikes. The alleged or apparent cause was the introduction among them of a non-diplomaed assistant who had not, or was not entitled to wear, the nurse's uniform, and it is alleged that when they left, the striking nurses or some one among them destroyed records, mixed up medicines, deranged glasses and bottles and concealed keys of instrument cases. The only thing apparently lacking was the picketing of the hospital and slugging, or perhaps hair pulling and scratching of their substitutes. Next to the physician's the nurse's should be an altruistic profession, but these particular nurses seem to have had a very low ideal of their duties and status. It is to be hoped that the action of these nurses will not be imitated by others, but that, if the facts are as charged, they will be promptly condemned and repudiated by their associates.

SCIENCE AND REST.

An opportunity to escape from the turmoil of this commercial world is often eagerly sought by the phy-

sician no less than by others. With the omnipresent mail and telegraph pursuing him, he begins to find it hard to secure a place for quiet recreation. Unless he can take an ocean voyage, the busy physician sometimes solves the problem by stealing away into the wild woods, his location being known to but one trusty friend. An ocean voyage has been long considered an ideal of freedom from care. Here the brain-fagged worker could read no daily paper, hear of no startling crime or commercial unheaval, receive no urgent letter or telegram on business matters, and the days passed amid quiet but novel and interesting scenes. But the quiet of this scene is threatened. We are told that while on her voyage many miles from land a ship received news by wireless telegraphy, a newspaper was printed and laid by the breakfast plates of the passengers. So it may not be long ere the busy physician can take his ocean voyage, but yet not get away from his g. p's. Hawaii, once called "the paradise of the Pacific," and delightfully free from worry because all outside news was at least a week old, is now connected by cable and is no longer in "charming isolation and yet accessibility." Thus by the advance of science the world becomes smaller and smaller until there will be no place left whither weary man may escape for rest.

COMPELLING TEMPERANCE BY LAW.

The saying that "You can not make a man temperate by act of parliament" has evidently a British origin and there has certainly been no tendency heretofore in that dominion toward prohibitory laws. Notwithstanding this, it seems to be a fact that one of the most stringent anti-liquor laws has just gone into effect there, and the consequences will be worth watching. Instead of being prophylactic against drunkenness in the way of prohibition, it is directly punitive. Drunkenness itself is made an offense, whether the individual is disorderly or not, and repeated convictions make the offender, as it were, a habitual criminal subject to compulsory detention for a considerable period up to three years. The appearance before the court and conviction more than a certain number of times, moreover, puts the individual on a published blacklist, and the personal responsibility of dramsellers as regards those thus listed is to be stringently enforced. The working of the law will be watched by all who are interested in the reduction of the evils of intemperance. If inebriety is a disease, as some claim, the provisions of the law would appear to be harsh, unless, indeed, we assume that, though a disease, it does not diminish responsibility. Probably the British magistrates will accept this view if the disease theory is pleaded before them, and it would certainly be unreasonable to permit disease to be a license to commit offenses against good morals and public welfare. The London and Glasgow police will have their hands full if they construe the law with any strictness and the licensed dealers will have to walk in narrower paths than they have been accustomed to if they wish to keep out of trouble.

LIFE-SAVING INVENTIONS.

The prevention of loss of life has been the subject of a number of recent inventions and some of these appear to promise something of real value. Anything that will reduce the amount of suffering and loss of life incident to travel is in line with the physician's plan of labor. One of the measures proposed is the use of acetylene to prevent the sinking of ships. The inventor proposes the placing of packages of calcium carbid throughout the lower parts of the ship in connection with collapsed gas bags. On the entrance of water it will reach the carbid and generate acetylene gas, which will inflate the bags and keep the ship afloat. The inventor has not told us how he proposes to prevent the explosion of the gas, or its ignition. Some of us might prefer to go down than up, or to drown than burn. Turning to railroads, we find a telephonic connection proposed between different engines by means of a third-rail system. On the approach of one train to another a signal is given, the engineer may then stop and telephone and learn the conditions. A more noteworthy plan is a system holding the drive wheels of the locomotive by magnetism to the rails. It is urged that this will prevent all accidents in case brakes fail to work on hills, in case slippery rails prevent the stopping of trains and in many cases where trains would otherwise leave the track. But the most promising invention is one by which electric connection is established through the rails to the engine so as to control the throttle of the locomotive. Whenever a locomotive approaches too near to another, a short circuit is established which automatically shuts the throttle, applies the brakes and stops the train. This would seem to remove an element of human fallibility. If any of these pass beyond the experimental and theoretical stage, where so many inventions linger, they will be welcomed into the equipment of the railway systems.

JUSTIFIABLE SUMPTUARY LEGISLATION.

The protest against "sumptuary legislation" is the war cry of the man who considers it an inalienable right of the individual to eat and drink what he pleases. It is frequently raised and for selfish ends. A similar protest is that against legislation that seeks to have those who treat disease qualified to some extent. One of these protests was by Mark Twain, who urged that a man should not be limited in his choice of a physician. Since the legislation was to restrict incompetence it was equivalent to saying that a man should be allowed to die in any way he chooses. This would not be bad for a joke, but no joke was intended. A man is emphatically not privileged to die as he chooses, nor to eat and drink what he pleases. It is now recognized as a right of the community to forbid the sale of liquor to the habitual user of intoxicants, and the sale of cocain, of carbolic acid and of other drugs where proper use is not intended, and the sale of embalmed beef and of salicylic-acid-preserved food. No one disputes the right. The latest curtailment of alleged sumptuary rights is the action of the Board of Health of Ithaca, N. Y., the scene of the recent typhoid epidemic. It is made a misdemeanor, punishable by $50 fine or fifty days in jail, for anyone to drink unboiled city water or to furnish it to others for that purpose. Who will question their right to take this action? Two score homes bereaved, every available physician overworked, hospitals full, the work of a great university almost suspended, hundreds of lives threatened and the future health of

the locality in jeopardy from the pollution—the community has indeed the right to limit individual acts that add to these perils. The rights of man and the rights of men are coming more and more to be interpreted in the light of ultimate results and for the greatest good to the greatest number.

Medical News.

ALABAMA.

College To Be Renovated.—A bill has been introduced in the house appropriating $20,000 for the renovation of the building of the Medical College of Alabama, Mobile.

Smallpox Among Medical Students.—The health officials of Mobile have discovered eleven cases of smallpox among students of the Medical College of Alabama, Mobile.

Rhett Memorial.—The new operating room at the City Hospital, Huntsville, erected and equipped by the City Council in memory of the late Dr. R. Barnwell Rhett, Jr., was recently opened.

Personal.—Dr. T. Chilton Thorington, Montgomery, has been appointed captain and assistant surgeon, S. T. Ala., and assigned to the Second Infantry, vice Dr. Walter S. Britt, Eufaula, resigned.——Dr. Henry M. Hunter, Union Springs, has located in the City of Mexico.——Dr. William M. Faulk, who has been a member of the staff of Bryce Hospital for the Insane, has resigned, and will practice in Tuscaloosa.

GEORGIA.

The Cocain Question.—In a trial at Atlanta, March 3, the fact was elicited that at one drug store in that city more than 3000 prescriptions for cocain had been filled within two months.

Want Scholarships.—Applications are pouring in on the governor for appointment to scholarships in Augusta Medical College, under the law whereby the governor is authorized to name two persons from each of the eleven congressional districts of the state for free scholarships at this institution.

Society Victorious.—The Supreme Court has confirmed the decision of the lower court for the defendants in the case of E. S. E. Bryan versus the Atlanta Society of Medicine. Bryan brought action against the society for $10,000 damages on the ground that his name had been presented to the grand jury as an illegal practitioner of medicine.

Violation of Cocain Law.—Dr. O. H. Snider, Atlanta, arraigned on the charge of distributing free packages of cocain to negroes, was found guilty, February 25, and fined $500, a thirty days' sentence in the stockade, and bound over to the city court on a $1,000 bond. On his promise not again to offend, the fine was reduced to $100.——W. C. Moran, Atlanta, on March 3, was fined $100 and costs for dispensing cocain in a box which did not bear the red label required by law.

ILLINOIS.

To Repeal Law of 1901.—Representative Miller has introduced a bill to repeal the law of 1901 requiring reports of births and deaths and the recording of the same, and the registration of interments or other disposal of dead bodies.

Senate Bills.—A bill has recently been introduced in the senate giving the osteopaths representation on the State Board of Health; another abolishing the State Board of Health, and a third abolishing 56 of the 61 trustees of the state charitable institutions and vesting full control of these institutions, 16 in number, in a state commission of public charities.

Medical Practice Act.—On March 6 Representative Wheeler introduced the new medical practice act proposed by the Illinois State Medical Society. It creates a State Board of Medical Examiners, consisting of seven members, who shall be appointed by the governor with the advice and consent of the senate. The appointments are to be made from persons nominated by the state medical societies, and every incorporated society having an actual membership of not less than 100 licentiates in medicine and surgery and embracing membership from at least twenty counties may submit nominations. The term of office is to be seven years.

Smallpox.—During February 180 cases of smallpox were reported to the State Board of Health from 45 localities in 34 counties. In 1902 there were about 4,000 cases in the state in February, and the diminution is undoubtedly due to the persistent efforts of the State Board of Health to enforce vaccination. Difficulty is still found in handling the disease, because it is often not at first recognized as smallpox. Spread of the disease in many localities is due to the refusal of the local health authorities to accept the diagnosis of the attending physician. They call on the State Board of Health for an inspector before taking action, and many may be exposed before he comes.

Chicago.

Health Department Appropriations.—The Department of Health estimated its needs for 1903 at $188,000; the city comptroller made an estimate of $188,619, and the budget calls for $188,000.

New Hospital Site.—It is announced in the daily press that negotiations are in progress for the sale of the old West-Side baseball park, 560 by 640 feet, to Cook County, for $125,000, to be used as the site for a contagious-disease hospital.

Smallpox.—During the week ended March 7, 13 cases of smallpox were discovered; two patients died at their homes and 11 were removed to the isolation hospital. There are now nearly 60 patients at the hospital, and 20 deaths have occurred.

Physician Sued.—In the suit of Mrs. Parmelia J. Davis against Dr. Edwin H. Pratt for $3,000 damages on account of an operation alleged to have been illegally performed on her, by the defendant, without her or her husband's consent, the court gave judgment for the plaintiff for the full amount.

Fewer Deaths.—There were 118 fewer deaths reported during the week ended March 7, than during the previous week—a decrease of 16.5 per cent., says the Bulletin of the Health Department. The mortality rate is still excessive, however, when compared with that of 1902. The total deaths for the week numbered 595, as against 713 for the last week in February and 515 in the corresponding week of 1902.

Physicians Protest.—Physicians attached to the county agent's office protested, March 2, against the new method of paying for their services. They were formerly paid $50 a month. The new appropriation provides that they shall be paid $1.50 a call. The chairman of the finance committee said it was the intention to redistrict the city and to so systematize the work that long trips would be unnecessary.

INDIANA.

Osteopath Bill Defeated.—On March 4 the senate defeated Senator Johnston's bill, providing a separate board of examination and registration for the osteopaths of the state.

Suit Settled by Death.—The case of James M. Shelley against Dr. George W. Spohn, Elkhart, for $10,000 damages on account of alleged improper treatment of cancer, was abruptly terminated, March 9, by the death of the plaintiff.

Unclaimed Cadavers for Dissection.—The governor signed the bill giving unclaimed bodies to medical colleges for dissection on payment of expenses of shipment, on February 26. As this law repeals "all laws within the purview of this act," it includes the law under which resurrectionists were convicted, but it is believed that as the bill became a law after the indictments were returned, it will have no effect on these cases.

Disease in January.—Smallpox for the twenty-fourth consecutive month leads the list as the most prevalent disease, 921 cases, with 50 deaths, were reported. The increase in smallpox, as compared with the corresponding month last year is enormous, and was predicted by the State Board of Health. There was a 98 per cent. increase in number of cases, 80 per cent. increase in area covered, and 90 per cent. increase in the number of deaths. The order of prevalence of diseases was as follows: Smallpox, tonsillitis, bronchitis, pneumonia, rheumatism, influenza, typhoid fever, scarlet fever, pleuritis, diarrhea, intermittent fever, diphtheria and croup, erysipelas, whooping cough, measles, inflammation of bowels, puerperal fever, dysentery, cerebrospinal meningitis, cholera infantum, and cholera morbus.

January Deaths.—There were 2,910 deaths reported in January—a death rate of 13.6 per 1,000. The greatest number of deaths, 410, was caused by pneumonia, and the next, 302, by consumption. Typhoid fever caused 64 deaths, diphtheria 53, scarlet fever 23, whooping cough 19, cerebro-spinal meningitis 33, influenza 39, cancer 88, violence 129, and smallpox 50. The city death rate was 16.8, and the county death rate 11.9 per 1,000. Compared with January, 1902, there is an increase of .4 in the death rate for January, 1903. There is a decrease in the death rate from consumption of 16.4 in 100,000. There is also a decrease in typhoid fever, pneumonia, influenza, violence

and smallpox. There were only five deaths from smallpox in January, 1902, which compared with 50 in January, 1903, shows a very great increase.

LOUISIANA.

State Board of Health.—Dr. Edward Souchon, New Orleans, has been re-appointed president of the board, and Dr. Joseph S. Stephens, Natchitoches, and Percival B. McCutcheon, New Orleans, members.

Charity Hospital Report.—The annual report of the hospital shows revenues for the year of $134,799.14 and expenditures of $126,042.15, leaving a balance of $8,756.99. During the year the hospital received $34,895.21 from donations and legacies. There were 6,793 patients admitted during the year.

Near a Million for Tulane.—By the will of the late A. C. Hutchinson, the bulk of his estate is devised to Tulane University Medical Department. The estate is appraised at $991.169. The brother of the deceased has begun suit at New Orleans to break the will on the ground that the university is not competent to receive the bequest.

Personal.—Dr. Arthur W. D. Roaldes, New Orleans, has been made an officer of the Legion of Honor of France.——Dr. Jefferson D. Bloom has been re-elected house surgeon; Dr. James M. Batchelor, first assistant house surgeon; Dr. Joseph A. Danna, second assistant house surgeon; Dr. Oliver L. Pothier, pathologist, and Dr. Maurice J. B. Couret, assistant pathologist, of Charity Hospital, New Orleans.

MARYLAND.

The Shooting at Westport.—Dr. Houghton Boxley was fined $10 and costs for firing a pistol at Dr. John Floyd at Westport, a suburb of Baltimore, February 27. He claimed that he shot in self-defense. He was bound over to keep the peace for six months.

Deaths and Disease.—There were 202 deaths in Baltimore for the week ended March 7, an annual rate per 1,000 of 18.63. There were 37 deaths from pneumonia; 9 from bronchitis; 6 from la grippe, and 3 from measles and 2 from diphtheria. A few new cases of diphtheria and measles were reported, but the epidemic of the latter has almost subsided.

Dr. Flexner's "Bacteriolysin."—Dr. Flexner is engaged in manufacturing his dysentery antitoxin, or "bacteriolysin," as he terms it. Trial will be made of this antitoxin this summer at the Wilson sanitarium near Baltimore. In about 2 months Dr. Flexner will institute a course of instruction for about 30 young men at his laboratory in Philadelphia, on the identification of the dysentery bacillus, so that during the summer a very widespread study of the summer diarrheas of children in this country may be made. It is rumored that Dr. W. G. MacCollum, associate professor of pathology at the Johns Hopkins Medical School, may succeed Dr. Flexner at the University of Pennsylvania.

MASSACHUSETTS.

Foot and Mouth Disease.—Dr. A. J. Peters, chief of the cattle bureau, having discovered that a case of "foot and mouth disease" had been imported from New Hampshire, has arranged with the Boston and Maine R. R. that no more cattle, sheep or swine shall be brought into Massachusetts from that state over that system till the danger from the infection is over.

Personal.—Dr. W. R. Brinckerhoff, assistant pathologist of the Boston City Hospital, will soon go abroad for a year's study.——Two changes in the staff of the Massachusetts General Hospital are the resignation as visiting physician of Dr. William L. Richardson, and the appointment as visiting surgeon of Dr. Charles L. Scudder.

Faulkner Hospital Opened.—The Faulkner Hospital, Jamaica Plain, Boston, which has been built and fitted up at an expense of $100,000 by Dr. and Mrs. George Faulkner as a memorial to their daughter Mary, was opened for inspection February 25, and for the care of patients March 9. The hospital has 25 beds and is thoroughly equipped. Dr. Frank Balch and Henry Jackson are in charge, and are assisted by a staff made up from the physicians of that vicinity.

Bequests to Hospitals.—By the will of the late Jacob H. Hecht more than $50,000 is given to charities. Among the hospitals thus aided are the Massachusetts General Hospital, Boston Lying-in Hospital, St. Mary's Lying-in Hospital, Boston Emergency Hospital, and the Carney Hospital.——The Children's Hospital, the Perkins Institution for the Blind, the Eye and Ear Infirmary, the Carney Hospital, Massachusetts General Hospital, Boston City Hospital, School for Crippled and Deformed Children and the New England Peabody Home for Crippled Children are among the beneficiaries of the will of the late W. I. Bolton of Chelsea, Mass.

MISSOURI.

Moves into New Quarters.—The medical department of the Missouri University, Columbia, moved, February 24, into the new $40,000 building recently erected for it.

Influenza Raging.—It is reported that there are 15,000 cases of influenza in St. Louis. Nearly ten per cent of the 700 patients in the City Hospital are said to be suffering from the disease.

Hospital Saturday and Sunday.—The annual report of the Hospital Saturday and Sunday Association of St. Louis shows collections of $24,732.66, with expenses of $755.09. The association distributed $23,000 among the associated hospitals of the city.

College Commencements.—Central Medical College, St. Joseph held its graduating exercises, February 27. Dr. Thompson E. Potter delivered the faculty address, Dr. Edward T. Molzahn was valedictorian, and the diplomas were presented to a class of 24 by Dr. Moritz F. Weyman, president of the college. ——On February 28, a class of 14 received diplomas from Ensworth Medical College, St. Joseph. Dr. Wallace B. Deffenbaugh delivered the address on behalf of the faculty, and Dr. Thomas H. Doyle, president of the college, conferred the degrees.

New Bills.—By Mr. Baker, to establish a hospital in State Hospital for the Insane, No. 1 Fulton, for the detention and treatment of dipsomaniacs and inebriates and those addicted to excessive use of narcotics.——By Dr. Horace D. Quigg, Cooper County, providing for the appointment by the governor of three separate medical boards, one for each of the three schools of medicine, each board to consist of five members and they to examine applicants for their respective schools and issue licenses to those found qualified.——By Mr. Dorris of Oregon, to require the State Board of Health to issue certificates to practice medicine to all graduates of reputable medical colleges without examination.——By Mr. Brown, Ozark, to allow graduates from a four-year course medical college to practice medicine without examination, provided they apply for authority to practice within three months of their graduation.

NEW YORK.

Hospital for Crippled and Deformed.—The New York State Hospital for the Care of Crippled and Deformed Children, Tarrytown, has issued its report for the year ended Sept. 30, 1902. During this period 35 patients have been treated, of whom 10 have been discharged. About 150 applications for admission have been made during the year, but owing to the restricted accommodations the larger portion could not be accepted. If the hospital had been equipped with 5500 beds the surgeon-in-chief says he could have filled them in a month with deserving patients.

State Charities Aid Association.—The thirteenth annual report of this association shows that in the past year 1,158 children have been placed in families at an expense that is a mere trifle compared with that which would have been incurred if these children had been cared for in institutions. This, of course, takes no account of the good to the children and to the community resulting from family life for young children as compared with rearing in institutions. A committee of the association co-operates with the Department of Charities of New York City in caring for motherless infants. In this way 112 motherless babes were cared for in the past year, while in the past four years 127 such infants have been provided with permanent homes before reaching the age of two years. By the same means the mortality among foundlings has been reduced from over 95 per cent. to less than 11 per cent. The total number cared for since the beginning of this work in 1898 is 303.

Typhoid Legislation.—Senator Stewart of Ithaca with an interest in the public health quickened by the fact that his wife is ill with typhoid at his home, has introduced into the legislature a bill aiming at preventing the pollution of the waters of the state. The bill provides that permission will hereafter have to be obtained from the state commissioner of health for any person, shop, factory or industrial establishment to discharge sewage or other putrescible matter into the waters of the state after the same shall have been forbidden by any local board of health or other public authority. The penalty for the discharge of sewage from any public sewer system without a permit is $500, and $50 a day while the nuisance is maintained.

The penalty for discharging into any of the waters of the state any other matter prohibited by this bill is to be $25 and $5 a day for each day the offense is continued. At the request of Dr. Frederick Holme Wiggin, president of the New York State Medical Association, the committee on legislation of that body is actively to support this bill.

New York City.

Skene Avenue.—The suggestion is made that the name of the late Dr. Alexander J. C. Skene be perpetuated by the naming of some suitable avenue in Brooklyn.

Found Lectureship.—Dr. and Mrs. Christian A. Herter have given $25,000 to Johns Hopkins University, Baltimore, for the establishment of a lectureship in medicine.

Charges Unfounded.—The sensational charges recently made by an alcoholic patient in Bellevue Hospital against the nurses have been carefully investigated and, at the request of the district attorney, the case was dismissed because the charges were found to be without foundation.

Columbus Hospital.—This institution is to be enlarged shortly by the addition of new buildings, adjoining the present property, the ground for which has already been purchased. The erection of these new buildings will increase the capacity of the hospital from 98 to 150 beds. Funds for the erection of the buildings are available, which will be sufficient to provide for modern equipment of the new wards.

A Nurses' Strike.—Nine of the trained nurses of the New York Eye and Ear Infirmary left the hospital on the refusal of Dr. Richard H. Derby, the executive surgeon, to accede to their demand that the new head nurse and an objectionable assistant be removed. For a short time the service of the hospital was badly crippled by this high-handed action, but several nurses were sent from other institutions to render assistance in the emergency.

Suit for Death in Narcosis.—In the suit brought against Drs. John A. Wyeth and W. H. Landon White by Mrs. Alice Wood, as administratrix of the estate of her son, Robert Wood, deceased, for damages sustained by him by reason of alleged negligent treatment, the Appellate Division of the Supreme Court dismissed the case on its merits. The boy, who was being operated on by Dr. Wyeth for an infected wound of the arm, died under chloroform, and suit was thereon instituted. It will probably be carried to the appellate court.

Personal.—Dr. Frederick C. Keller has been appointed attending physician to Columbus Hospital, to succeed Dr. Farquhar Ferguson, who has been made consulting physician.——Dr. G. A. De Santos Saxe has been appointed assistant pathologist to Columbus Hospital.——Dr. George L. Peabody has resigned his position as professor of materia medica and therapeutics in the College of Physicians and Surgeons.——Dr. John Harrigan has been elected president of the staff of St. Mary's Hospital, Brooklyn, vice Dr. John J. Byrne, deceased.

Buffalo.

Personal.—Dr. Edward L. Frost has been appointed physician to the Erie County penitentiary, and Dr. Prescott Le Britien physician to the jail.——Dr. Marshall Clinton has been appointed attending surgeon at the Buffalo Hospital, Sisters of Charity.

Foreign Bodies in Stomach.—Dr. H. R. Gaylard recently made a gastrostomy on a patient at the Erie County Hospital, when the following articles, numbering 689 and weighing 2 pounds and 3 ounces, were removed from the stomach: One piece of chain 3 inches in length, 41 knife blades, 2 wire nails, 142 screws, 3 nuts, 452 sharp tacks, 48 shoemaker nails, 144 grammes of glass.

Typhoid Menace to Buffalo.—In an interview, Dr. Daniel Lewis, state commissioner of health, states that the condition of typhoid fever at West Seneca should greatly concern the people of Buffalo, for the reason that Buffalo has so many more people to be affected. The only remedy for Buffalo is to filter its water supply, and he is of the opinion that a filtering plant could be established for $750,000.

Marine-Hospital Site Selected.—Surgeon-General Wyman has reported to Representative Ryan in Washington the selection of about three acres of land on Main street, Buffalo, between the Providence Retreat and the Deaf and Dumb Institute, as a site for the new United States Marine-Hospital. The selection is based on the recommendations of Dr. L. L. Williams and Francis B. Wheaton, who were appointed a commission to act with Dr. Eugene Wasdin. It is one of the highest points of land in the city. There is stone three feet below the surface and excellent drainage.

OHIO.

Fire in Dayton.—A loss of about $1,500 was sustained by Dr. Dagobert A. Scheibenzuber, whose house was much damaged by fire, February 17.

Semi-Centenary in Practice.—On February 20, Dr. Bernhard Krause, Cleveland, celebrated the fiftieth anniversary of his graduation in medicine from the University of Göttingen, Germany.

Serious Accident.—Dr. Abijah J. Miles, Cincinnati, on February 27, while crossing a street, was struck by a street-car, causing a deep scalp wound in the back of the head and a compound fracture of the skull.

PENNSYLVANIA.

Concealed Smallpox.—The board of health of Chester will order the arrest of two hospital patients on the charge of their having concealed the fact that they had smallpox.

Must Not Use Name Without Permission.—The legislature has passed a law prohibiting the use of a person's name or picture as a testimonial for a patent medicine without the individual's consent.

Norristown Hospital Crowded.—The State Hospital for the Insane at Norristown is so over-crowded that 205 men and 192 women have to sleep on cots in the corridors. The inmates number 1,012 men and 1,097 women.

Diphtheria Unreported Quarantines Hospital.—Charity Hospital of Norristown, containing 32 patients and about a dozen nurses, has been placed under strict quarantine by the board of health, because a case of diphtheria which developed in the institution was not reported for several days.

Osteopathic Examiners.—The house of representatives recently gave a hearing to advocates of a bill to provide for an osteopathic board of examiners to grant license to practice ostopathy to those who have studied twenty months—five months in four different years—and have graduated from an osteopathic college.

Philadelphia.

Hospital Bequest.—Jefferson Medical College Hospital recently received a bequest of $5,000 from the estate of the late Thomas Elkinton.

Hospital Applies for Charter.—Frankford Hospital, occupying temporary quarters on Frankford avenue, has applied for a charter. As the nearest hospital is three miles distant, the new hospital will supply a need, especially for the treatment of emergency cases. The hospital now has accommodation for 40 patients.

Typhoid Not Abated.—As shown by the official report, the typhoid fever epidemic has not abated. For the week ended March 7 there were 254 new cases, as compared with 255 for the previous week. The general death-rate in the city is still high, there being 614 deaths, as compared with 508 for the corresponding week of last year.

Personal.—On March 3, Dr. A. Palmer Dudley, New York, operated in the gynecologic clinic of Jefferson Hospital. In the evening he gave an address to the members of the E. E. Montgomery Gynecological Society and their friends, and was afterward a guest of honor at the annual banquet of the society.——Dr. C. S. Ely has resigned as resident physician at Jefferson Hospital, having passed the examination for admission to the Navy.

Regulation of Barber Shops.—A meeting was recently called in Philadelphia by the International League of Barbers to further the passage of a bill by the Pennsylvania legislature providing sanitary regulation of barber shops. The proposed law provides for the licensing and registration of barbers, and requires their better education. It also provides for a board of examiners, of five members, who shall have been actually engaged in the business at least ten years. The movement is supported by the International Union of Journeymen Barbers.

Homeopaths Want Hospital.—In a recent message to the council, Mayor Ashbridge calls attention to the fact that for several years homeopathic physicians have been asking recognition on the medical boards of the Philadelphia Hospital; that since the enactment of an ordinance removing the Municipal Hospital from its present site, committees representing the homeopaths have several times waited on the mayor with petitions that, on removal of the institution, the present municipal hospital buildings and grounds be turned over to

them for a public homeopathic hospital for the treatment of non-contagious diseases. The message closes as follows:

In compliance with this request, I have the honor to lay the suggestion before your honorable bodies, and would ask that you have it referred to the appropriate committee. Inasmuch as a very large proportion of our citizens believe in the homeopathic method of treatment, I am of the opinion that the suggestion merits the very best consideration at your hands.

GENERAL.

Pension for Mrs. Walter Reed.—Congress has passed a bill appropriating $125 per month during her lifetime as a pension to Mrs. Emily Lawrence Reed, widow of the late Major Walter Reed, U. S. A.

Plague Spreads in Mexico.—A few cases of plague have appeared at points near Mazatlan, viz., El Oso, Villa Union and Lapaz. The outbreak seems to have been entirely subdued at El Oso by vigorous measures. The sanitary officials who burned plague-infected houses at Villa Union were mobbed. None was seriously hurt. Soldiers were sent there and precautions taken against the further spread of the disease.

The Diphtheria Antitoxin Question.—By invitation of Prof. Joseph P. Remington, chairman of the committee of revision of the United States Pharmacopeia, eight prominent physicians and bacteriologists recently met with him to consider the advisability of inserting diphtheria antitoxin in the Pharmacopeia. The state boards of health of New York, Pennsylvania and Massachusetts, the Army and Navy, and two prominent manufacturing firms were represented in the meeting. No definite decision is announced.

That Decreased Birth Rate.—Congress has passed a resolution recommending that state and municipal authorities cooperate with the Census Bureau in securing uniform and complete registration of births and deaths. It is said that the United States is behind European governments in this respect. Further statistics on the birth rate are appearing in the lay press, and some of these are quoted here, their accuracy not being guaranteed. The average annual rates of increase of the population, calculated by the excess of births over deaths, are as follows: Mothers of native birth and parentage, 19.5 per 1,000; foreign parentage, 36.5; colored, 17.8. In New England the native rate is 3.8 and the foreign 39.6. The census gives very meager information on the birth rate. About all the statistical summary possible is to deduct the number of deaths and the number of immigrants from the apparent increase of population. The total population of the United States in 1890 was 62,947,714, and the natural increase during the next ten years was 12,315,361. The average annual rate of excess of births for those ten years was 17.7 per 1,000 of population. The death rate was 16.3 per 1,000 in 1900 and about 8 per cent. per 1,000 in 1890, as given in the census reports of that year. Taking the mean of these, as representing the average annual death rate for the decade, there must have been an average annual birth rate of 35.1 per 1,000 to produce the increase of population. This rate is said to exceed the rates in some European countries. Their rates are given as follows: Hungary, 40.5; Austria, 37.2; Germany, 37.2; Italy, 35.5; England, 30.1; France, 22.2. Returning to the United States, a tabulated statement of the states is given. The lowest birth rate is among the native families of New England (3.8 per 1,000). In Connecticut it is the lowest of any state (1.8 per 1,000), while in Utah we find the highest percentage (63.1 per 1,000). The following table shows the excess of births over deaths per 1,000 of the population among native white parents:

Utah	63.1	Illinois	22.8
Idaho	48.3	Iowa	29.8
Wisconsin	41.2	Missouri	26.3
Minnesota	40.0	Nebraska	22.2
Texas	38.7	Kansas	21.6
North Dakota	35.3	Indiana	16.3
Louisiana	35.8	Michigan	19.3
West Virginia	33.9	Ohio	12.9
Arizona	36.8	Pennsylvania	14.0
Montana	32.2	New York	8.9

The following table shows the birth rate among the foreign-born population:

Utah	41.7	Illinois	43.9
Idaho	50.8	Iowa	31.0
Wisconsin	34.5	Missouri	17.1
Minnesota	53.4	Nebraska	43.7
Texas	53.2	Kansas	30.0
North Dakota	92.1	Indiana	19.4
Louisiana	11.2	Michigan	40.1
West Virginia	25.2	Ohio	21.9
Arizona	52.5	Pennsylvania	36.8
Montana	73.2	New York	36.6

There is an interesting table in the census reports showing that among the foreign population of the United States the fecundity of the different races of mothers during the ten years from 1890 to 1900 was in the following order: Bohemian, Russian, Hungarian, Italian, Scotch, Scandinavian, Canadian, English, German, French, Irish. The officials of the census office believe that the true birth rate of the country was probably much higher than 35.1 per 1,000. As near as they can calculate, it should be about 10 per cent. higher.

CANADA.

Dominion Board of Health Wanted.—Drs. Roddick and Lachapelle of Montreal and Dr. R. W. Powell of Ottawa had an interview last week with the premier with regard to the establishment of a Dominion board of health to take charge of all matters affecting public health.

Trinity Consolidation.—Arrangements are now being completed whereby Trinity Medical College will become the Medical Department of Trinity University. For some months a committee has been at work. It is understood that a very fine site has been secured adjoining the present medical college building, on which new and modern buildings, to cost perhaps $200,000, will be erected.

Richardson Testimonial.—It is the intention of the old students of Dr. J. H. Richardson, Toronto, to tender him a banquet in April, and to present him a portrait of himself in oil. Dr. Richardson, who was born in 1823, was appointed professor of anatomy in the University of Toronto in 1850. Three years ago he gave up active teaching and was appointed emeritus professor. He is still surgeon to the Toronto jail.

For Fifty Years a Medical Teacher.—This is the record of Dr. Uzziel Ogden of Toronto, who recently retired from the chair of gynecology in the University of Toronto. He may now be given the emeritus professorship. Dr. Ogden commenced practice in 1849 and commenced lecturing in medicine in 1853. He was the first editor of the *Canadian Practitioner and Review* when that journal was established in 1876 as the *Canadian Journal of Medical Science*.

McGill University Union's Building.—The graduates of McGill University have decided to mark the seventy-fifth anniversary of the commencement of lectures by the formation of a students' union and the erection of a building to be used by the union as a home. The anniversary will occur next year; and it has been decided that the building should cost $75,000 of which $10,000 has already been subscribed. This amount has been promised by two members of the McGill Graduates' Society, of New England. A canvass of the entire graduate body of McGill will be made to raise the balance. Dr. Craik, late dean of the medical faculty, was elected president.

Personal.—Dr. Gilbert Gordon, professor of hygiene in Trinity Medical College, Toronto, is recuperating at Old Point Comfort.——Dr. R. Barrington Nevitt, dean of the Woman's Medical College, Toronto, is paying a visit to his birthplace in Georgia.——Dr. Lapthorn Smith, Montreal, will read a paper at the International Medical Congress at Madrid.——Dr. C. F. Martin, associate professor of medicine in McGill University, has been delegated by the Canadian Medical Association and the American Pediatric Society to the International Medical Congress at Madrid.——Dr. W. H. Drummond of Montreal was given a reception by the Canadian Society of Philadelphia February 27.

FOREIGN.

The Thirty-second German Congress of Surgery will be held at Berlin, June 3 to 6, 1903.

The German Society of Orthopedic Surgery will hold its second annual congress at Berlin, June 2.

Chodin Endowment.—The pupils and colleagues of Professor Chodin of Kiev recently endowed two free beds in the Eye Hospital in his name on the occasion of the thirtieth anniversary of his connection with the university.

Projected Sanatoria for the Poor in Belgium.—It is proposed to found a stock company in Belgium for the erection of inexpensive sanatoria for lung diseases. The prices will be not over 40 to 60 cents a day. The capital is only $40,000, and aid is expected from the state.

Opening of Dispensary at Manila.—A free dispensary has been opened at Manila by a dozen American and Philippine physicians, Dr. Albert, president of the "Federal Party"; Dr. E. H. Winslow, surgeon to the constabulary, and Dr. H. W. Yemans, secretary; Drs. G. Ageo, P. H. Lyon, Lukban, Bautista, and others.

Charity Home for Physicians.—Dr. C. Rasch of Kropp bei Schleswig, Germany, is agitating the necessity of establishing

a home for physicians convalescing from diseases, and also for the superannuated, with, possibly, a view to including the members of physicians' families in its projected benefits. Our German exchanges endorse the necessity for such an institution "on account of the growing financial distress of our profession," and hope that the seed will fall on fruitful soil.

The Campaign Against Charlatans in Germany.—According to a regulation introduced last year, charlatans, before settling in a town, must report to the local medical authorities. The quacks now add to their advertisements: "Nature healer, duly reported to the local medical authority," *beim Kreisarzt Angemeldeter Heilkundiger*. This clause seems to express the official sanction of their practices, so that the regulation in question promotes quackery instead of combating it, as intended.

An American Professional Man's Club, composed in large part of physicians who are studying in Berlin, has been recently organized there, with headquarters at the Hotel Terminus. It is a source of much practical benefit to American physicians arriving in Berlin. Its objects are to promote social intercourse and the discussion of new and interesting professional matters and to afford information as to how and where to find the most practical professional work. Our correspondent says that this organization fills a long-felt want in Berlin, and that the club decided to notify the American medical profession through The Journal.

A Medical Woman of the Second Century.—Galen mentions a cataplasm "according to Antiochis," and Heraclides also refers to the same woman physician. An Austrian scientific exploring party found, in 1892, in the ruins of Tlos, a city in Asia Minor, the pedestal of a monument bearing the following inscription: "Antiochis, daughter of Diodotus of Tlos, honored by the senate and the people of Tlos for her experience in the medical art, has erected this statue to herself." No traces could be found of the statue. Baudouin establishes the identity of the person referred to in these three references, as a supplementary note to his work on "Woman in Medicine."

The Latest Charlatan Suit in Germany.—The charlatan Nardenkötter of Berlin, in a suit that has been dragging for two years, has been fined $750 and condemned to three years' imprisonment on the principal count, and to $150 fine and sixty days' imprisonment on another. The case was briefly mentioned in The Journal, Feb. 21, page 526. He had a regular physician in his employ, Dr. Kronheim, who signed the charlatan's prescriptions and received about $40 a month for his work in this line, to which he devoted an hour a day. He was condemned to six months' imprisonment and "loss of honor for one year,"—*zu einem Jahre Ehrverlust*. The charlatan diagnosed and prescribed by mail, and the suit revealed practices among the druggists who put up his prescriptions which have led to a suit against one of them. The drugs prescribed were heroic remedies in many cases, and most exorbitant prices were charged. The details of the case have been fully written up in the lay papers and must have enlightened part of the public, at least, in regard to the dangers of quackery, although our German exchanges express little hope of this possibility. The *Allg. Med. Ct. Ztg.* of February 21 gives the particulars of the suit.

LONDON LETTER.

Lead Poisoning from "Plumbo-Solvent" Drinking Water.

A valuable and elaborate report on this subject by Dr. Houston has just been issued by the medical department of the local government board. As long ago as 1885 the attention of the department was directed to a considerable number of cases of lead poisoning in Sheffield which were believed to be due to the drinking water. Investigation showed that the water was acid in reaction, especially at its origin in the peaty moorlands, where it collected in depressions. This acidity was found to be due to the life processes of bacteria contained in the moist peat. The present report shows that the property of "plumbo-solvency" is generally destroyed when the water possessing it is mingled with a large volume of neutral or acid-neutralizing water derived from other sources. In other instances filtration through sand or neutralization with lime or whiting may be adopted. But local authorities are warned of the need of bearing in mind the risks incidental to using plumbo-solvent water. It is declared undesirable to rely wholly on any system of neutralization. It should be first ascertained whether acid water can be altogether rejected from the supply, as by eliminating special peaty areas or by providing "leaping weirs" which insure that the first washings from the peat after a period of drought are automatically cast aside. The most satisfactory method of neutralization is sand filtration, with the addition of some neutralizing material to the filter and the subsequent addition of a trace of carbonate of soda to the neutral filtered water. But, whatever methods are adopted, they should be checked from time to time by suitable observations on the gathering areas, at the reservoirs and at the filters, as well as by examination of the water delivered to consumers.

Drunk or Dying?

The ever recurrent error of mistaking a serious injury or lesion of the brain for drunkenness has aroused the ire of London coroners and of the press against some of the great hospitals. Under the head of "A Grave Scandal" the *Hospital* insists on the necessity of providing a few emergency beds at each hospital, where this type of case could be kept under observation. Yet such are provided at only four out of the twelve great hospitals. A provincial coroner stopped the scandal of inquests coming before him of dying patients turned away from hospitals as drunk by declaring that in the next case he would commit the chairman of the committee and the superintendent of the hospital for manslaughter.

Non-Septic Puerperal Pyrexia.

At the Edinburgh Obstetrical Society Dr. Lamond Lackie read a very important paper on this subject. He pointed out that while most of the cases of fever in the puerperium are septic and in cases of doubt should be treated as such, yet septic organisms are not the only cause of fever. He related several cases. Dr. Lackie called attention to a very important practical point, which several of the cases illustrate: He has several times observed a rigor after administering an intrauterine douche, but always in cases in which the result showed that there was no retention of septic material. On the contrary, when the douche was needed the result was a fall of temperature.

Correspondence.

The Identity of Nerve Force and Electricity.

Richmond, Ind., March 7, 1903.

To the Editor:—My attention has been called to a paper read by Professor Loeb of the University of Chicago early in January, 1902. My reason for addressing you is this, viz.: to direct attention to work done, experiments made by myself, and conclusions reached, which will anticipate by priority his deductions and conclusions, as I understand them in his paper. I desire to mention my papers which have been read and published as early as 1873, 1875 and 1879, and papers since those dates which were published in the *Chicago Review* and are along the line recently indicated by Professor Loeb as "recent progress." I noticed the same, and desire to make my claim good, since 1873, in papers read and published. If, as he claims, the views are recent progress, I have anticipated him more than twenty years, as I was then teaching anatomy and physiology in the medical schools of Indianapolis. I only desire to mention the subject of each paper, as showing the subject and title.

First. My presidential address before the Indiana State Medical Society, May, 1873, subject "Vital Dynamics or What Is Force." 1. What Does It Represent? (Motion.) 2. What Are Its Relations and Correlations? 3. What are its Conservations?

Second. "Proofs of the Identity of Electrical Force and Nervous Force." A paper read at Indianapolis in 1879 before the Marion County Medical Society.

Third. Some papers on the relations of nervous force in the contraction and dilatation of blood vessels, also of heart dilatation and contraction, which were published in the *Chicago Medical Review*, copies of which are in my possession. (1884, September.)

A quotation is here made from this paper for the purpose of showing its basis: "The blood which is arterial, is the fluid which charges the battery, the brain, and hereby is generated force which is supplied to all tissues, and this charge, be it nervous or electrical, is a force which is universal in one form or another." The main question is, "What are the endowments and true relations of nervous tissue?" If we look at the re-

sults of mind and its power to impress other forces, we believe the evidence of our senses, and say that the directing forces in the entire universe were from mind, and this is the *primal* mind.

Now I have other papers which continue the thought of electricity and nervous force, and my last one is Jan. 1, 1902, with the title "Natural and Preternatural Law," in which are discussed "The Influence of Electricity and Mind in the Industrial and Economic Forces of the World."

These papers will establish my claim to priority on the questions at issue, and I desire now to only point to the proofs.

R. E. HAUGHTON, M.D.
Formerly Professor of Clinical and Operative Surgery in Central College of Physicians and Surgeons, Indianapolis.

Committee on Prophylaxis of Venereal Diseases.

NEW YORK, March 4, 1903.

To the Editor:—At the last (fifty-third) meeting of the American Medical Association, held at Saratoga Springs, June 10-13, 1902, a joint resolution from the Sections of Cutaneous Medicine and Surgery and Hygiene and Sanitary Science was introduced in the House of Delegates, as follows:

WHEREAS, There is a burning necessity to check the spread of venereal diseases, and, assuming that the States can not with impunity ignore the condition, it lies in the province of the medical profession to discuss and recommend to the respective state legislatures and municipalities means not regulamentative, but social, economic, educative and sanitary in their character, to diminish the danger from venereal diseases.

Resolved, That the Section on Cutaneous Medicine and Surgery of the American Medical Association invite the Section on Hygiene and Sanitary Science to co-operate with the Section on Cutaneous Medicine and Surgery in bringing about a propaganda in the different states, looking toward a proper recognition of the dangers from venereal diseases, and to arrange for a national meeting under the auspices of the American Medical Association for the prophylaxis of venereal diseases, similar to the International Conference for the Prophylaxis of Venereal Diseases, which meets again this year at Brussels, under the authority of the Belgian Government.

This was later submitted to the House of Delegates, which endorsed the action of the section and adopted the following:

Resolved, That a joint committee of six from the Sections on Hygiene and Sanitary Science and Cutaneous Medicine and Surgery be appointed by the President to stimulate study in and uniform knowledge of the subject of the prophylaxis of venereal diseases and to present to the American Medical Association a plan for a national meeting, similar to the International Conference for the Prophylaxis of Venereal Diseases, which meets again this year in Brussels, under the auspices of the Government of Belgium.

The Committee on Prophylaxis of Venereal Diseases consists of Drs. Henry D. Holton, chairman, Brattleboro, Vt.; Ludwig Weiss, secretary, 77 East 91st Street, New York; George M. Kober, 1600 T Street, Washington, D. C.; W. H. Sanders, Montgomery, Ala.; L. Duncan Bulkley, 531 Madison Avenue, New York City; and Frank H. Montgomery, 100 State Street, Chicago.

The peculiar social, racial and political conditions of our country are so different from those on the continent that they necessitate an expression of solely American ideas on this mooted question, both from a socio-economic and sanitary point of view. The committee desires the support of the medical profession and the aid and powerful collaboration of the medical press of the country to help them in this work. It takes the liberty of soliciting expressions and views editorially and otherwise, and would be glad of personal correspondence from those supporting the movement and who will contribute by papers, etc., to make it a success in case the House of Delegates should favor the holding of such a congress.

LUDWIG WEISS, M.D., Secretary of Committee.

The Chicago Water Supply.

CHICAGO, March 6, 1903.

To the Editor:—In the Bulletin of the health department for February, 1903, there is a comment on my paper "The Fly as a Carrier of Typhoid," published in THE JOURNAL, which seems to require an answer.

The Bulletin quotes my statement that the value of daily reports issued by the board of health as to the condition of the water "becomes somewhat problematical when one considers that twenty-four hours must always elapse between the collecting of the water and the published report, so that the people who read on Tuesday morning that the water at a certain station is bad and take precautions accordingly are a full day late, for they were drinking the bad water on Monday." It then proceeds to explain that the water samples are collected at the pumping stations between 8 and 9 o'clock each morning, and that the results of the analyses are given to the press before noon and appear in the afternoon papers of the same day, and that, as the pumping stations are several miles out, the water does not reach the city until several hours after the character has been announced.

I must explain the seeming inaccuracy of my statement by saying that it was based on a sentence in Dr. Reynolds' paper in the *Medical Recorder*, 1902, vol. 23. "By 'good' in the laboratory characterization is meant a water free from pathogenic organisms, the colon group." If, as would appear from this statement, the water is examined bacteriologically, eighteen hours at least would be required, but from the statement in the Bulletin it is evident that the examination is only chemical, not bacteriologic.

Even if it were true, however, that a chemical examination is sufficient, that would not alter my contention that the daily bulletins as to the state of the water are misleading. Water which changes its character with every change of wind and current and with every heavy rainfall is always dangerous. The sample examined on any particular morning represents a small portion of water for a very limited period of time. On Monday morning, for instance, the water "is good," on Tuesday morning "bad." At what time did the change take place? And is it not possible that on Monday morning also a part of the water was "bad," although not the particular portion taken for analysis?

The daily examination of the water may be valuable from the point of view of the statistician and the sanitary engineer, but the publication of the results as "warnings" to the people simply serves to lull them into a false security.

ALICE HAMILTON.

Silkworm Gut, Not Silk, for the Sustaining Sutures in Fixation of the Kidney.

NEW YORK, March 7, 1903.

To the Editor:—In THE JOURNAL of March 7, page 665, in the report of the proceedings of the New York County Medical Association it is incorrectly stated that I prefer silk for suturing the kidney. I employ temporary sutures of silkworm gut which are brought out through all the structures of the back and tied over a fold of gauze.

AUGUSTIN H. GOELET, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

MEDICAL PRACTICE IN TEXAS AND AFRICA.

AGRICULTURAL COLLEGE, MISS., March 5, 1903.

To the Editor:—Please let me know what the requirements are for the practice of medicine in Texas. W. H. B.

ANS.—Examination is required in Texas, but the certificates of twenty states, including Mississippi, are recognized by the state board in lieu of examination. A list of these states was given in this column last week.

NASHVILLE, TENN., February, 1903.

To the Editor:—Kindly inform me through your valuable columns of the requirements for practice in Orange River Colony and Transvaal, South Africa. G.

ANS.—We have no copy of the laws of the Transvaal under the new government and have not learned that a medical council has been organized. A proclamation was made last year requiring license from the secretary of the Transvaal administration, presentation of diploma and proper identification. The applicant must be legally qualified in his own country, which must grant equal privileges to qualified British subjects. We do not know if any changes have been made since.

MADSTONES.

DUNKIRK, IND., March 9, 1903.

To the Editor:—We have through the Ohio valley what are known as madstones. They are small stones, usually found among the collections of some relic-hunters and have a real or fabled history of having been a cure-all for poisoned wounds, snake-bites, dog-bites, etc. J. B. GARBER.

ANS.—There is no scientific evidence that they have any effect other than a moral one.

State Boards of Registration.

The New South Dakota Law.

A law just enacted in South Dakota regulating medical practice provides for a board of seven members appointed by the governor, not more than four from the regular school, two from the homeopathic and one from the eclectic. The board is to hold two regular meetings, beginning on the second Wednesday of July and the second Wednesday of January each year and such additional meetings and at such times and places as the board may deem advisable. Applicants must give satisfactory proof of being at least 21 years of age and of good moral character, and must pass an examination on the following subjects:

Anatomy, physiology, chemistry, pathology, therapeutics, practice of medicine, surgery, obstetrics, gynecology, diseases of the eye and ear, bacteriology, medical jurisprudence and such other branches as the board may deem advisable, and in addition thereto shall present evidence of having attended four full courses of lectures of at least twenty-six weeks each in a legally organized and reputable medical college recognized by the board of medical examiners, no two courses being in the same year and of having received a diploma from a legally organized and reputable medical college which shall be in good standing as shall be determined by the board, and said diploma must be submitted to the board for inspection and verification: provided, that the four courses of lectures of six months each shall not apply to applicants who graduated prior to 1898.

The applicant, before being permitted to take the examination, shall pay the secretary of the board an examination fee of $20; the examination shall be written, oral or both, as the board may determine; the questions on all subjects except therapeutics and practice of medicine shall be such as may be answered alike by all schools of medicine. The applicant shall, if possible be examined in therapeutics and practice of medicine by those members of the board belonging to the same school as the applicant, and a license and certificate shall not be refused any applicant because of his adherence to any particular school of medicine. An average of at least 75 per cent. of correct answers is required. Any applicant who fails to pass the examination shall be eligible to a second examination at the next meeting of the board or at such time as the board may designate without an additional examination fee.

License can only be granted by the consent of not less than five members of the board and shall be signed by the president and secretary and attested by the seal of the board. All examination papers, together with the lists of questions answered shall be kept for reference and inspection for a period of not less than three years.

The law contains a reciprocity clause as follows:

The said board may, in its discretion, accept and license on the payment of the license fee and without examination of the applicant, any license which shall have been issued to him by the medical examining board of the District of Columbia, or any state or territory of the United States; provided, however, that the legal requirements of such examining board shall have been at the time of issuing such certificate or license in no degree or particular less than those of the state of South Dakota at the time when such certificate or license shall be presented for registration to the board created by this act: and provided, further, that the provisions of this section contained shall be held to apply only to such of said medical examining boards as accept and register the certificate or license granted by this board without examination by them, of the persons holding such certificates or license. Each applicant on making application under the provisions of this section shall pay to the secretary of the board a license fee of $20.

The board shall have the power and authority to revoke any license of any physician or surgeon heretofore or hereafter granted or issued, on complaint made to it on oath by one responsible person if it shall satisfactorily appear to the board: 1, that such physician or surgeon has been guilty of unprofessional, immoral or dishonorable conduct; or 2, that such physician or surgeon has been convicted of a felony; or 3, if such physician or surgeon publicly professes to cure or treat disease, injury or deformity in such a manner as to deceive the public; 4, if he shows gross unprofessional incompetency, provided that such license shall not be revoked except after a hearing before the board of medical examiners at which at least five members of such board shall be present and of which hearing the person holding the license to be revoked shall have had net less than ten days' written notice of the time and place of said hearing and only on due proof of the facts stated in the complaint.

The words unprofessional or dishonorable conduct as used in Sections 11 and 12 of this act are declared to mean:

1. Procuring or aiding or abetting a criminal abortion.
2. The employing of what is known as cappers or steerers.
3. The obtaining of any fee on the assurance that a manifestly incurable disease can be permanently cured.
4. Wilfully betraying a professional secret.
5. All advertising of medical business in which untruthful or improbable statements are made or which are calculated to mislead or deceive the public.
6. All advertising of any medicine or any means whereby the monthly periods of women can be regulated or the menses re-established if suppressed.
7. Conviction of any offense involving moral turpitude.
8. Habitual intemperance.

Appeal to the Circuit Court can be made in case of revocation or refusal to grant certificate. Itinerant physicians are charged a license of $500 annually.

Licenses must be recorded in the office of the register of deeds in the county where the holder resides and practices. The register of deeds shall in July and January of each year furnish the secretary of the board of examiners a list of all licenses so recorded.

The definition of the practice of medicine is given in the following:

Section 21. When a person shall append or prefix the letters "M.B." or "M.D." or the title "Dr." or "Doctor," or any other sign or appellation in a medical sense to his or her name or shall profess publicly to be a physician or surgeon, or who shall recommend, prescribe or direct for the use of any person any drug, medicine, apparatus or other agency for the cure, relief or palliation of any ailment or disease of the mind or body, or for the cure or relief of any wound, fracture or bodily injury or deformity, after having received or with the intent of receiving therefor, either directly or indirectly any bonus, gift or compensation, shall be regarded as practicing within the meaning of this act.

This act shall not apply to the commissioned surgeons of the United States Army, Navy or Marine-Hospital Service in actual performance of their duties, nor to regularly licensed physicians or surgeons from outside this state in actual consultation with physicians of this state nor to dentists or osteopaths in the legitimate practice of their profession nor to christian scientists as such, who do not practice medicine, surgery or obstetrics by the use of any material remedies or agencies, nor to resident physicians and surgeons of this state regularly licensed and practicing in this state at the time of the taking effect of this act; provided, however, that the license heretofore or hereafter granted to any physician or surgeon may be revoked for the same reason and in the same manner as stated and provided in Sections 12 and 13 hereof.

Penalties are provided for impersonation or violation of the law, and it is made the duty of the state's attorney to prosecute. The law has an emergency clause which makes it in effect immediately on its passage.

Proposed New Jersey Law.

The State Board of Medical Examiners of New Jersey has introduced a bill into the legislature requiring applicants for a state license to submit certified evidence of an academic education embracing a certificate or diploma issued after four years of study either in a normal, manual training or high school of the first grade in that state, or in a legally constituted academy, seminary or institute of equal grade, or a student's certificate of examination for admission to the freshman class of a reputable literary college, or an academic education considered and accepted by the state superintendent of public instruction as fully equivalent.

The medical requirements are four full school years of at least nine months each, including four satisfactory courses of lectures of at least seven months each, in four different calendar years prior to graduation from a legally incorporated medical college in good standing.

Provision is also made for graduates in practice prior to 1894, by accepting ten years of continuous and reputable practice as the equivalent of two courses of medical lectures, and for graduates in practice prior to 1903, by accepting five years as the equivalent of one course of lectures, provided that such substitution or exemption be specified in the license.

Book Notices.

BIOGRAPHIC CLINICS. The Origin of the Ill Health of De Quincey, Carlyle, Darwin, Huxley and Browning. By George M. Gould, M.D., Editor of *American Medicine*. Cloth. Pp. 223. Price, $1.00. Philadelphia: P. Blakiston's Son & Co. 1903.

Whatever the accomplished editor of *American Medicine* may write is sure to be interesting. His writings have a positive, aggressive note about them that is refreshing and invigorating.

These characteristics and his versatility are well shown in this latest work, a study from the borderland between pure literature and medicine.

Dr. Gould takes five great Englishmen, De Quincey, Carlyle, Darwin, Huxley and Browning, each of whom it will be remembered was a great physical sufferer, and makes a critical study of the afflictions. All this suffering Gould believes was due to eye-strain. This is the object of the book, to prove that unrecognized and untreated refractive errors with consequent eye-strain drove De Quincey to opium, made Jane Welsh's husband an inconsiderate, ill-tempered dyspeptic tyrant, deprived Darwin of the power of long continuance at study of books or with the microscope, and caused Huxley and Browning to groan with the tortures of unexplained and almost constant headache. Numerous quotations are given from the letters of these men or of their contemporaries bearing on their health, striving to show that whenever the eyes were used for near work complaints appear of headache, nervousness, sleeplessness, biliousness, indigestion, etc. When reading and writing are dropped, especially when open-air work or recreation is indulged in, i. e., when little strain for near accommodation is demanded of the eyes, the complaints of ill health cease.

Whatever may be our views concerning eye-strain as a cause of headache and other disorders of health, and however prejudiced we may be at first as to the relation of refractive errors to the ill health of these five men in particular, we can not read this really fascinating book without feeling that the author has advanced a strong chain of circumstantial evidence in favor of his view. Nor can we avoid agreeing with him that in the light of our present day knowledge it seems disgraceful that no physician appears to have made even crude tests of vision and surprising that such scientific men as Darwin and Huxley apparently never once have suspected that there might be ocular defects to explain their suffering.

It seems to us that the author weakens his cause by his last chapters on the topic of eye-strain as the cause of various reflex phenomena. His views seem extreme. If we understand his statement—about the only one that is at all involved or the least obscure (p. 154)—he believes that "at least 90 per cent." of such symptoms as "headache, dyspepsia, 'biliousness,' sick-headache, migraine, neurasthenia, anemia, vertigo, insomnia, anorexia, constipation, eructation of gas, languor, ill-temper, melancholia, etc., are not caused by dietary indiscretion or organic disease, and of these, over 90 per cent. are reflex ocular neuroses, i. e., due to eye-strain." "Most eye-strain is due to astigmatism."

To the physician in general practice this will seem a broad and incredible statement. Granting that there is truth in Dr. Gould's statements that Nature cares for the delicate and all-important eye by making the rest of the body the vicarious sufferer, granting that the modern physician in his eager study of infectious diseases neglects the non-infectious and functional diseases and that he pays too little attention to "the reflex" and overlooks especially the reflex symptoms due to the eye, granting that glasses are not prescribed as often as they should be because of popular prejudice, or because "the eyes do not hurt," granting that many oculists are careless and unscientific, that opticians are worse and that the "muscle-cutters" are faddists, granting all this, yet who of wide experience in practical medicine can believe that the one great cause of 80 or 90 per cent. of headaches and a very large proportion [80 per cent.] of "digestional" or "nutritional" diseases is to be sought in eye-strain, and that these headaches and "digestional" disorders together are direct or secondary sources of a large part of the functional diseases and misery of the world (p. 205). But if the general practitioner can not believe this what shall be said of the specialists other than the oculist? Where does the stomach come in? Must our old notions as to errors in diet being a fruitful cause of dyspeptic symptoms go? Farmers furnish some of the worst cases of digestional disease. And what about our hyperchlorhydria and the train of secretory disturbances? Will glasses correct 80 per cent. of these cases, and have all our cures by diet been mistakes? And then the gynecologist, what must be his feelings as he sees the general practitioner after reading this book, steering the neurasthenic woman not to the office of the man who would cure her by stitching up a torn cervix, cutting a piece out of an ovary, breaking up adhesions, putting the displaced uterus where he thinks it ought to be, but across the hall to the oculist, who cures it all by glasses. And then the floating kidney reflex and Glénard's disease, and the hypertrophied turbinated bones and hemorrhoids, are they all delusions? And is there no such thing, then, as a true nerve-tire and brain-fatigue? Is this all due to the eye?

Surely our author has been extravagant in his statements or else we have misunderstood them. And we confess that his use of the word "functional" has been a little confusing to us at times. Astigmatism is not, we believe, the source of all these ills, nor is the wearing of glasses a panacea. Let the multitudes of those who have worn them, carefully fitted, for headache but with no help, bear witness. Let the thousands of sufferers from migraine, an excellent example of heredity, an influence at which our author rather casts slurs—testify who have tried glasses in vain.

The results of uncorrected astigmatism are undoubtedly often serious and should be attended to. This book does good in forcibly calling attention to this fact, and is, as we have said, a most interesting and delightful discussion of a borderland topic. But while admitting that the causal relation of eye-strain to the physical ills of these five men is made highly probable by the proof advanced, we can not accept the broad conclusions and extravagant statements that are scattered here and there throughout the book making the bulk of the medical profession little short of criminals in their supposed neglect of the eye as the cause of a large share of human suffering.

In spite of these criticisms, in spite of the overly-enthusiastic claims of the author, we heartily commend this book to every practitioner. Eye-strain is a cause of many troubles, there is no doubt of it, and every physician should be made to realize it.

A TEXT-BOOK OF MATERIA MEDICA, THERAPEUTICS, AND PHARMACOLOGY. By George F. Butler, Ph.G., M.D., Professor of Materia Medica and Therapeutics in the College of Physicians and Surgeons, Chicago, Medical Department of the University of Illinois, etc. Fourth Edition, Thoroughly Revised. Handsome Octavo Volume of 896 Pages, Illustrated. Cloth, $4.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

In this fourth edition within the last six years the author has added to his valuable treatise considerable new and important matter, and it seems to be brought up to date as well as carefully revised. Some changes have been made in his expressions of opinion in regard to certain drugs and some of the newer ones that have not yet obtained pharmacopeial rank are included. The book seems likely to keep the good reputation that it has held in the past as one of the best recent text-books on materia medica and therapeutics.

THE MATTISON METHOD IN MORPHINISM. A Modern and Humane Treatment of the Morphin Disease. By J. B. Mattison, M.D., Medical Director, Brooklyn Home for Narcotic Inebriates. Cloth. Pp. 40. Price, $1.00. Published by the Author. New York: E. B. Treat & Co. 1902.

This little volume gives the method and treatment of one who is certainly experienced in handling a difficult class of patients, the morphin habitués. The author's method is largely sedation with bromids supplemented by other measures, and the gradual discontinuance of the morphin habit, not so very long drawn out either, for the whole treatment does not seem to usually exceed four or five weeks at the outside. It seems to be a very satisfactory little monograph.

Deaths.

Charles F. Ulrich, M.D. University of Louisville, Ky., 1870, a member of the American Medical Association, surgeon of volunteers during the Civil War; some-time president of the Wheeling and Ohio County Medical Society and Medical Society of the State of West Virginia; vice-president of the American Congress of Tuberculosis and member of the American Academy of Medicine, died from paralysis at his home in Wheeling, W. Va., February 18, aged 75.

Franklin B. Galbraith, M.D. University of Michigan, Ann Arbor, 1861, a member of the American Medical Association, surgeon to the Fourth Michigan Volunteer Cavalry in the

Civil War, and thrice mayor of Pontiac, Mich., died at his home in that city, February 21, from angina pectoris, after an illness of only ten hours, aged 63. At a special meeting of the Pontiac Medical Society, February 23, resolutions of sorrow and sympathy were adopted.

Martin Rockwell Gage, M.D. Geneva (N. Y.) Medical College, 1852, who retired from practice in 1892, died from consumption at his home in Sparta, Wis., February 25, aged 78. He was a pioneer physician and surgeon of western Wisconsin, and served as surgeon of the Twenty-fifth Wisconsin Volunteer Infantry during the Civil War. He was a number of the Wisconsin State Medical Society and of the American Medical Association.

Willard I. H. Mathews, M.D. Iowa College of Physicians and Surgeons, 1886, county physician of Polk County, major and brigade surgeon U. S. V., in the Spanish-American War, for a time surgeon-in-charge of the U. S. General Hospital, Presidio, San Francisco, and for several months on duty in the Philippine Islands, died at his home in Des Moines, Iowa, February 24, from pneumonia, after an illness of four weeks, aged 38.

George E. McPherson, M.D. Jefferson Medical College, Philadelphia, 1855, died at his home in San Francisco, February 20, aged 73. He was a surgeon in the United States service in the Civil War, and then located in Chicago, but moved to California in 1872. In 1896 he fell from his carriage, fracturing his hip, and two years ago had another fall, from the effects of which he never recovered.

Lemuel G. Goode, M.D. New York University, 1887, died at his home in Jersey City, N. J., from pleuro-pneumonia, February 24, after an illness of four days. Dr. Goode was one of the first medical men to be the subject of operation under spinal anesthesia. In December, 1901, his leg was amputated, and during the operation he made notes of his sensations.

John Gerdine, M.D. Tulane University, New Orleans, 1861, a member of the American Medical Association; president Clark County Medical Society; ex-vice-president Georgia Medical Association, and one of the most prominent and beloved citizens of Athens, Ga., died at his home in that city, February 18, from pneumonia, after an illness of two days, aged 63.

James Calvin Hall, M.D. College of Physicians and Surgeons, Baltimore, 1879, died suddenly from heart disease, while attending a lecture in Millerstown, Pa., February 11, aged 48. At a meeting of the physicians of Perry, Juniata and Snyder counties, held February 16, memorial resolutions were adopted.

Pumphrey H. Hood, M.D. Jefferson Medical College, Philadelphia, 1851, for half a century a resident of Litchfield, Ill., died at his home in that place, February 20, aged 79. He was a surgeon in the United States service during the Civil War, and represented Montgomery County in the legislature in 1895.

Frank Brownlie Newton, M.D. University of Vermont, Burlington, 1899, died at his home in Stafford Springs, Conn., February 19, from pneumonia, after an illness of eleven days, aged 28. He was a member of the Connecticut Medical Society.

Richard Jordan Gatling, M.D. Medical College of Ohio, Cincinnati, for some time a practitioner of Indianapolis, but better known as the inventor of the Gatling gun, died suddenly in New York, February 26, from heart disease, aged 84.

George C. Gage, M.D. College of Physicians and Surgeons, New York, 1872, a specialist in diseases of the nose and throat, died at his home in New York City, February 22, three weeks after an operation for appendicitis, aged 52.

George White Sloan, M.D. Indiana Medical College, Indianapolis, president of the American Pharmaceutical Society, died at his home in Indianapolis, from apoplexy, February 15, after an illness of four months, aged 67.

Joseph A. Jackson, M.D. McGill University, Montreal, 1879, a member of the New Hampshire Medical Society, died at his home in Manchester, N. H., from la grippe, February 20, after an illness of two weeks, aged 68.

Henry McQuiston, M.D. Western Reserve University, Cleveland, 1868, died at his home in Pasadena, Cal., from consumption, February 13, after an illness of four years, aged 65.

Robert Hamilton Ramage, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1872, Carnegie, Pa., died at a hospital in Pittsburg, from consumption, February 15, aged 61.

George Young, M.D., retired, of Pioneer, Ohio, died at St. Mary's Hospital, Detroit, February 15, from injuries received four days previously in a street-car accident, aged 64.

William T. Riddlemoser, M.D. College of Physicians and Surgeons, Baltimore, 1884, died at his home in Smithsburg, Md., February 18, from tubercular meningitis, after an illness of several weeks, aged 43.

John B. Liddell, M.D. Atlanta (Ga.) Medical College, 1880, died from pneumonia, February 22, at his home in Gadsden, Ala., after an illness of three days.

Cyrenius D. Spencer, M.D. Berkshire Medical College, Pittsfield, Mass., 1849, died from apoplexy at his home in Binghamton, N. Y., February 22, aged 77.

Edward H. Luckett, M.D. Kentucky School of Medicine, Louisville, 1854, died at his home in Owensboro, Ky., February 24, from heart disease, aged 70.

James I. Scollard, M.D. Albany (N. Y.) Medical College, 1874, died suddenly in his office in Clinton, N. Y., February 20, from heart disease, aged 75.

Ruel M. Rogers, M.D. University of Missouri, St. Louis, 1854, died at his home in Pleasant Grove, Utah, February 6, from pneumonia, aged 70.

Robert M. Means, M.D. Jefferson Medical College, Philadelphia, 1893, died at his home in De Haven, Pa., February 14, from pneumonia, aged 35.

David H. West, M.D. Eclectic Medical Institute, Cincinnati, 1874, was found dead in bed at his home in Calvert, Texas, January 12.

Association News.

NEW ENGLAND RATES TO NEW ORLEANS.

The New England Passenger Association has authorized the rate of a fare and a third to the eastern gateways of the Trunk Line Association. The rate from these points to Washington or western termini (such as Cincinnati) is the usual reduced rate for regular season excursion and approximates a fare and a third. The rest of the way to New Orleans the rate is one fare for the round trip. All these rates and regulations will be given in the New Orleans number of THE JOURNAL, April 11.

THE NEW ORLEANS PROSPECT.

A Quotation from the Memphis Medical Monthly Concerning the Annual Meeting.

"All physicians who contemplate being present—and what Southern medical man will not attempt to get there?—will be looking forward to this occasion with keen anticipation, and will be planning that nothing shall interfere with their arrangements to be in New Orleans for at least the four days of the meeting.

"New Orleans is always a pleasant city to visit, and conditions for pleasure and profit will be exceedingly propitious at this time. The medical profession of New Orleans are going to do everything conceivable to render this meeting the largest and most enjoyable that the Association has ever held, and the arrangements that they have practically consummated for the accommodation and entertainment of visiting physicians are noteworthy for their completeness. The business and scientific sessions of the Association and its various sections will be interspersed with a number of entertainments which promise to be most delightful, and the visitor from the North will have every opportunity to judge of the quality of the vaunted Southern hospitality, while the Southerner will be completely overwhelmed by the prodigality of this hospitality as lavished in New Orleans."

INDIANA'S PROSPECTS FOR NEW ORLEANS.

An Extract from an Advance Copy of the Indiana Medical Journal for March.

"New Orleans presents notable features. To the ordinary tourist the yearly carnival and the French opera are signal attractions. There are other matters of local color: The French market, the great river explored by Lasalle and its picturesque levees, the French and Spanish creole quarters, and the gastronomic privileges which rival those of Baltimore—the paradise of good things to eat of all the world.

"The Crescent City is the second in exports and twelfth in population. The invention of the cotton gin by Whitney and the successful granulation of sugar by deBore one hundred years ago, gave a vast impetus to the state and city, which was further increased by the Louisiana purchase in 1803. Five miles below the city is the battlefield of Chalmette, where, Jan. 8, 1815, after the treaty of peace had been signed, Jackson repulsed the 5,000 British regulars fresh from the Napoleonic battlefields, with a disparity of losses not excelled in history.

"The city has a tropical climate; the great magnolia, the palm, the banana, the fig, the orange tree are in evidence. Between the lake and the river the atmosphere is moist and equalized in temperature, the lowest 27 F. and the highest 94. In May the city is in its greatest beauty, and the health conditions the best of the year. For a spring vacation for the physician and his family the time and place is ideal, and we make bold to say that not less than 200 members of the Indiana profession and their families will take advantage of this opportunity to visit or to revisit the city of carnivals, creoles, market baskets, tropical vegetation and quaint people."

Medical Organization.

The Duty of the Hour.

That the enthusiasm in favor of organization is growing rapidly must be evident to all who come in contact with medical men in every section of the country. Of course there are scoffers and doubting Thomases, but all respectable members of the profession are heartily tired of the antagonistic spirit which has so influenced our personal, professional and educational affairs in the past. This spirit has so lowered us in our own and in the public estimation that many had come to believe it inseparable from our calling, but the profession as a whole is ready to give reasonable trial to any plan which promises even a hope of relief.

How to take this widespread sentiment at the tide and crystalize it into a permanent reform is the problem and duty of the hour. This is being admirably done in a few states, and in many counties in other states, and should be at once undertaken by the officials and members of existing societies everywhere. The magnitude of the work will be understood when it is authoritatively stated that there are over 70,000 licensed practitioners in this country who are not members of any kind of society, county, district, state or national.

In an experience extending into many states, and where nearly every possible condition was to be met, it has been found that the physicians of nearly any county would promptly respond to a kind and plainly expressed invitation from any recognized outside authority to meet and organize. If the preliminary discussion was frank as to existing evils, to the difficulties of maintaining local societies, and the certain reward, scientific, social and material, which would follow success, such organizations were easily made permanent. Some counties in several states are already reporting every physician within their boundaries as already members of the county and state society and of the American Medical Association.

Such results as these have not come spontaneously or by accident, but from the patient, systematic and self-sacrificing labors of some zealous member of the Association. With similar effort they are possible in all but a few sparsely settled counties of the Union. Officers of state societies and members of the Association everywhere are earnestly requested to consider the possibilities to the profession from such missionary work, and to feel free to apply to the organization department for literature and any other assistance at its command.

Southwestern Minnesota District and County Medical Society.

At its meeting, January 29, in Worthington, the organization of this society was perfected in accordance with the rules of the American Medical Association. Dr. Emil King, Fulda, was elected president and Dr. Herbert D. Jencks, Pipestone, secretary.

Hardin County (Ky.) Medical Society.

At the regular meeting, held at Elizabethtown, March 5, Dr. C. Z. Aud was elected president; Dr. James W. O'Conner, vice-president, and Dr. James C. Mobley, secretary and treasurer. The society adopted the constitution and by-laws prepared by the committee on organization of the American Medical Association.

Monroe County (N. Y.) Medical Association.

The members of the Fourth District branch of the New York State Medical Association, residing in Monroe County, met in Rochester, February 27, and organized this association by the election of the following officers: President, Dr. Thomas A. O'Hare; vice-president, Dr. Edward Mott Moore, and secretary and treasurer, Dr. James C. Davis, all of Rochester.

Societies.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, FIFTY-FOURTH ANNUAL MEETING, NEW ORLEANS, MAY 5-8.

Medical Society of the Missouri Valley, Council Bluffs, Iowa, March 19-20.
Florida Medical Association, St. Augustine, April 8.
Western Ophthalmological and Oto-Laryngological Association, Indianapolis, April 9-11.
Tennessee State Medical Society, Nashville, April 14-16.
Medical Association of Georgia, Columbus, April 15.
South Carolina Medical Association, Sumter, April 15-16.
Iowa State Medical Society, Sioux City, April 15-17.
Medical Association of the State of Alabama, Talladega, April 21.
Medical Society of the State of California, Santa Barbara, April 21.
Mississippi State Medical Association, Greenville, April 21-23.
Medical Association of the State of Missouri, Excelsior Springs, April 21-23.
Texas State Medical Association, San Antonio, April 28.
Louisiana State Medical Society, New Orleans, April 28-30.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 28-30.
Nebraska State Medical Society, Lincoln, April 28-30.
Illinois State Medical Society, Chicago, April 29-May 2.
Arkansas Medical Society, Jonesboro, April 30-May 2.

New York Academy of Medicine.—Dr. Lewis A. Conner has been elected chairman, and Dr. Ernest E. Smith, secretary, of the section on Medicine.

Redlands (Cal.) Medical Society.—At the annual meeting, January 21, Dr. Thomas M. Blythe was elected president; Dr. Christopher A. Sanborn, vice-president, and Dr. C. E. Ide, secretary and treasurer.

Red River Valley (Minn.) District and County Medical Society.—The first quarterly meeting was held at Crookston, January 27. Dr. Charles E. Dampier, Crookston, presided, and a banquet was tendered the society by Dr. George A. Morley.

St. Joseph (Mo.) Academy of Medicine.—Local physicians organized under this name, January 17, and elected Dr. James W. Heddens president; Dr. John B. Reynolds, vice-president, and Dr. William L. Kenney, secretary and treasurer.

Orange County (N. Y.) Medical Association.—The annual meeting was held in Middletown, January 21. Dr. Willis I. Purdy was elected president; Dr. William E. Douglas, vice-president, and Dr. Charles I. Redfield, secretary and treasurer, all of Middletown.

Rockland County (N. Y.) Medical Association.—At the annual meeting, held in Nyack, January 21, Dr. D. Burr Van Wagenen, Suffern, was elected president; Dr. George A. Leitner, Piermont, vice-president, and Dr. Norman B. Bayley, Haverstraw, secretary and treasurer.

Stark County (Ohio) Medical Society.—The annual meeting was held in Canton, January 17, when Dr. William C. Steele, New Berlin, was elected president; Dr. Frank W. Gavin, Canton, secretary and treasurer, and Dr. Frank E. Hart, Canton, corresponding secretary.

Quarter-Century Medical Club, Detroit.—The sixth annual banquet was held January 29. Dr. Henry A. Cleland was master of ceremonies; Drs. Justin E. Emerson and Albert E. Carrier were toastmasters, and Drs. Ernest L. Shurly, Leartus Connor and Justin E. Emerson were in charge of the arrangements.

Teller County District (Colo.) Medical Association.—The annual election, held recently, resulted as follows: Dr.

Marion A. Lattimer, Victor, president; Drs. William E. Driscoll, Goldfield, John A. Dunwoody, Cripple Creek, and J. S. Manley, Cripple Creek, vice-presidents; Dr. W. W. King, Cripple Creek, secretary, and Dr. John B. Polly, Elkton, treasurer.

Lavaca County Texas Medical Association.—The physicians of Lavaca County met, February 23, at Hallettsville, and organized a county association, electing the following officers: Dr. Walter Shropshire, Yoakum, president; Dr. James E. Lay, Hallettsville, vice-president; Dr. William E. Drisdale, Yoakum, secretary, and Dr. J. G. Guenther, Moulton, treasurer.

Richardson County (Neb.) Medical Society.—In accordance with the plan of the Nebraska State Medical Society, a county medical society was organized at Falls City, January 28, with the following officers: Dr. J. A. Waggener, Dawson, president; Dr. Anthony Keller, Falls City, vice-president, and Dr. Frank C. Wiser, Falls City, secretary and treasurer.

Southwestern Iowa Medical Association.—At the semi-annual meeting, held in Creston, February 19, the following officers were elected: President, Dr. J. E. Howe, Greenfield; vice-presidents, Drs. Charles H. DeWitt, Glenwood, and J. Frank Aldrich, Murray; secretary, Dr. Benjamin F. Gillmor, Creston, and treasurer, Dr. Joseph P. Claybaugh, Creston.

Hospital of the University of Pennsylvania Alumni Association.—On February 28 fifty former resident physicians of the hospital assembled at the University Club for their second annual banquet. Toasts were responded to by Drs. Barton Cooke Hirst, William E. Hughes, Charles H. Frazier, Edward Martin and John Carpenter. Dr. George E. de Schweinitz was elected president.

Ramsey County (Minn.) Medical Society.—At the annaul meeting in St. Paul, January 26, Dr. Angus MacDonald was elected president; Dr. H. Longstreet, vice-president; Dr. Ethelbert F. Geer, secretary; Dr. Frederick Leavitt, treasurer, and Dr. Alvah F. Whitman, necrologist. The constitution and by-laws were so amended as to permit any legal practitioner of non-sectarian medicine to become a member.

St. Clair County (Mich.) Medical Society.—The Port Huron Academy of Medicine changed its name to the St. Clair County Medical Society at its meeting, January 20, in order to become an integral part of the Michigan State Medical Society. Dr. Charles C. Clancy, Port Huron, was elected president; Dr. W. P. Derck, Marysville, vice-president, and Dr. A. Henri Cote, Port Huron, secretary and treasurer.

Sullivan County (N. H.) Medical and Surgical Society.—Physicians of Sullivan County met at Newport, January 28, and organized a county society to be in affiliation with the New Hampshire State Medical Society. Dr. Henry L. Stickney, Newport, was elected president; Dr. David P. Goodhue, West Springfield, vice-president; Dr. Fred P. Claggett, Newport, secretary, and Dr. Howard A. Hannaford, Grantham, treasurer.

Tuscola County (Mich.) Medical Society.—The physicians of the county met at Caro, January 19, and organized this society in conformity with the requirements of the American Medical Association and the Michigan State Medical Society. The following officers were elected: Dr. Arthur L. Seeley, Mayville, president; Dr. John E. Handy, Watrousville, vice-president; Dr. Wynee C. Garvin, Millington, secretary, and Dr. Frank D. La Valley, Vassar, treasurer.

Olmsted County (Minn.) Medical Society.—At the annual meeting, January 21, in Rochester, the following officers were elected: Dr. Arthur F. Kilbourne, Rochester, president; Drs. Charles L. Chapple, Rochester, and Charles E. Fawcett, Stewartville, vice-presidents, and Dr. Hugo Speier, Rochester, secretary and treasurer. The reorganization under the rules of the State Medical Society was voted, and a committee appointed to revise the constitution in conformity therewith.

Upper Mississippi Medical Association.—At a meeting in Brainerd, January 19, the physicians of that section of the state perfected an organization to be affiliated with the Minnesota State Medical Society, embracing the counties of Morrison, Crow Wing, Aitkin, Cass, Beltrami, Wadena and Hubbard. The following officers were elected: Dr. Walter Courtney, Brainerd, president; Dr. John J. McKinnon, Wadena, vice-president; Dr. John A. Thabes, Brainerd, secretary, and Dr. J. G. Millspaugh, Little Falls, treasurer.

Boston City Hospital Alumni Association.—The annual meeting was held recently. For the first time the associate members, who include past and present members of the visiting staff, were present. The club now numbers nearly 300. Ninety more were voted in at this meeting. The officers for the coming year are: President, Dr. Charles P. Bancroft, Concord, N. H.; vice-president, Dr. Chauncey C. Sheldon, Lynn, Mass.; secretary, Dr. William H. Robey, Jr., Boston, Mass., and treasurer, Dr. William H. Prescott, Boston, Mass.

Union Medical Association of Northeastern Ohio.—The one hundred and twenty-sixth quarterly meeting was held in Akron, February 10. The membership of the association is 140, distributed over the 15 northeastern counties of the state. The following officers were elected: President, Dr. Charles E. Norris, Akron; vice-presidents, Drs. Edward Lauder, Cleveland, and Frank C. Reed, Akron; secretary, Dr. John H. Seiler, Akron; corresponding secretary, Dr. Charles W. Milliken, Akron, and treasurer, Dr. Harold H. Jacobs, Akron.

THE PHYSICIANS' CLUB OF CHICAGO.

Regular Meeting, held Feb. 23, 1903.

Dr. Henry B. Favill in the Chair.

The general subject was "The Prevention of Tuberculosis."

The Reasons for a Special Effort to Prevent the Spread of Tuberculosis.

Dr. William A. Evans was the first speaker, and gave the following reasons for prophylactic effort: First, the subject is worthy of consideration by this or any other body; second, there is no special reason for efforts at prevention unless there is some hope that that effort can be made successful; third, there is reason for special effort, in view of the fact that it will not prove unavailing.

Discussing the first of these reasons, he said that tuberculosis still remains the chief source of death, and the subject of prime consideration. In the ten principal cities of this country tuberculosis is responsible for 18,763 deaths, or 10.8 per cent. of the total death rate each year. Compared with other infectious diseases, which receive greater attention in the matter of prevention than tuberculosis, the relation in Chicago to diphtheria is 4 to 1; scarlet fever, 7 to 1; typhoid fever, 7 to 1. Kohler's statistics show that between the ages of 15 and 60, one-third of the people die from tuberculosis. According to Biggs and Prudden, there are in the City of New York at any given moment twenty thousand people who are rendered unproductive by reason of this disease.

Can tuberculosis be cured? According to the statistics compiled by Dr. Appel, U. S. A., in charge of Ford Bayard Sanitarium, 7.4 per cent. of cases are clinically cured, 11.6 convalescent, 34.9 improved, 25.2 unimproved, and 20.9 per cent. die. Dr. Evans quoted the statistics of other writers.

The question of prevention of tuberculosis resolves itself into hygiene, general hygiene and ventilation. Prevention must be effected, not only by the medical profession, but by the laity, who are most directly concerned and largely responsible for the spread of this disease. Laws are the result of public action; public action is slower than public conscience, and public conscience lags far behind public intelligence.

In What Way Can the General Practitioner Assist in the Purposes of the Crusade?

Dr. N. S. Davis, Jr., said that the position of the general practitioner in this movement is educative, but his influence should not be limited to educating patients only. It is essential to educate those who must be associated with them. Patients should live in light rooms, where there is good ventilation, and where the surroundings are clean and hygienic.

There is also a need for places where patients can be educated to care for themselves; where they can be taught by object lessons, seeing others who have improved under proper hygienic surroundings. To-day there is scarcely a hospital in Chicago which is willing to take these cases, because they are not prepared for them.

There is another advantage to be gained by admitting tuberculous patients to general hospitals. Every trained nurse should have experience in the care of cases of pulmonary tuberculosis.

The Committee on the Prevention of Tuberculosis of the Visiting Nurses' Association, Chicago.

Dr. Arnold C. Klebs read a paper with this title. The outline of the work as approved by the committee is as follows:

In general, considering the fact that the family members of a consumptive and those living in unhealthy conditions are the ones most threatened by the disease, education on the subject and eventually proper material aid have to be furnished to them primarily. The distribution of instructive pamphlets alone usually proves insufficient. It is, therefore, necessary to enhance the value of such printed instructions by personal interviews and repeated visits. For this purpose the co-operation of specially trained physicians and nurses, with the assistance of charity organizations, is deemed of importance. To facilitate such co-operation and to insure the uniformity of the measures to be employed, it is planned to establish a central office. From this office the general work is to be directed and carried out in district offices in the different parts of the city.

The work in the central office (1) is to be done by an executive committee of six, to be elected from (2) the general committee of forty, of which twelve are to be physicians. (3) A special tuberculosis fund may be established, if necessary. (4) Work to be done in the central office.

1. To collect and file all information. To ascertain the causes for the greater prevalence of the disease in certain districts. To examine the conditions of life in those districts, especially the condition of dwellings. To start a collection of literature on tuberculosis, especially in its socio-economic aspect. To maintain correspondence with other organizations.

2. To prepare instructive reading matter for distribution among (1) the public, (2) nurses, and (3) physicians.

3. To make arrangements for public lectures.

4. To co-operate with health authorities.

5. To disinfect houses.

6. To procure information about healthful occupations, eventually furnishing positions.

7. To decide on the advisability of transferring persons to other climates, eventually providing them with positions abroad.

8. To plan, found and eventually maintain health farms.

9. To advance the introduction of modern methods in existing institutions.

10. To test new ideas which promise results.

11. To supply the needy with food, medicines, disinfectants, spit cups, etc.

12. To extend aid to all efforts at organization.

13. To examine all cases applying for help and treatment.

14. To found district offices, each to have physicians and nurses in charge.

The essayist stated that as long as sanatoria can not be had, sanatorium methods must be used in the houses of the consumptives. To make the movement successful, every physician and layman ought to learn about it and help it in every possible way.

Discussion.

DR. ROBERT H. BABCOCK said that whenever tuberculosis has been diminished, it has been through the intelligent efforts of the medical profession. The first step in this educational movement should be the education of the medical profession. Many physicians are entirely oblivious to the necessity of preserving proper hygienic measures.

DR. WALTER M. FITCH called attention to the fact that a well-developed active chest is not so susceptible to infection, and much can be done to overcome this susceptibility to the disease.

DR. GEORGE W. WEBSTER emphasized the importance of institutional treatment; each patient, when he returns home, becomes an educated center, from which accurate information is disseminated. In the schools and universities more time should be devoted to the teaching of public hygiene, and less time to music and other studies of less value. Dr. Webster offered the following resolution, which was adopted:

Resolved, That it is the sense of the Physicians' Club that its members heartily approve and endorse the plan proposed by Dr. Klebs for preventing the spread of pulmonary tuberculosis.

DR. L. HARRISON METTLER suggested that properly guarded articles be given to the public press. The public can be reached better through the daily paper than through any other medium.

DR. A. M. CORWIN referred to the poor architecture, from the standpoint of hygiene, of the modern building, saying that the atmosphere in most of them is foul, because of insufficient ventilation and poor lighting facilities.

DR. ARNOLD C. KLEBS believes that the public would resent any intrusion by public officers in a disease which affects the victims rather slightly. He thinks a private movement would be more successful than one instituted by legislation. The poor people appeal for physicians, for nurses, and to charity organizations, and through these channels they can be instructed and educated.

DR. JOHN A. ROBISON said much can be done if pressure is brought to bear on the city officials, so that they will give the local board of health more power to carry out proper sanitary measures.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting of the Section on Pediatrics, Jan. 8, 1903.

Henry Heiman, M.D., in the Chair.

Ulcero-Membranous Stomatitis of Vincent.

DR. W. N. BERKELEY presented a boy of six years whose tonsil presented on the upper margin a deeply-excavated ulcer. Smears from this showed the spirillæ and elongated bacilli described by Vincent as characteristic of this form of stomatitis. As yet but little was known concerning the relation of the spirillæ to the bacilli.

DR. CHARLES HERRMAN said he would predict that future bacteriologic study would show that this same ulcerative process occurred in other parts of the body than the throat.

A Case of Malnutrition Apparently Dependent on Hyperplasia of the Blood Vessels and a Small Heart.

DR. SARA WELT-KAKELS presented a little girl who was evidently badly nourished and very anemic. The speaker said that although the child was born at full term she had always been delicate and more backward than her sisters. Since last June she had suffered from severe and constant headache, associated with constipation and loss of appetite. A hypermetropia in both eyes had been corrected by glasses without relieving the headache. Examination showed the cardiac impulse to be in the fourth intercostal space and the peripheral arteries so small that it was frequent in counting the pulse to feel the brachial instead of the radial artery. There was some cyanosis at times. The gastric contents had been examined after a test breakfast with negative result except that there was some deficiency in the hydrochloric acid. The daily quantity of urine was between 350 and 500 c.c. instead of the normal quantity, 1,140 c.c., and the daily quantity of urea was only 6.25 gm. whereas it should be 18 gm. The blood pressure had been determined by means of the Gärtner tonometer to be 69 mm., the normal varying between 100 and 120 mm. Even the microscopic examination of the blood was negative. An *x*-ray examination of the chest in conjunction with the fluoroscope had given a remarkably clear view of the thoracic organs, and showed plainly the diminutive size of the heart. Dr. Welt-Kakels was of the opinion that the child's condition was mainly dependent on a hyperplasia of the blood vessels.

Report of a Case of Paroxysmal Hemoglobinuria.

DR. CHARLES HERRMAN reported this interesting case, which occurred in a boy of four years, of apparently healthy parentage. In infancy he had presented evidences of congenital syphilis and had been treated for this disease for about twelve months. He was anemic and below the average size of a boy of his age. The heart and lungs were normal, and the spleen was not enlarged. Malaria was excluded by the failure to find the plasmodia in the blood. The attacks of hemoglobinuria came on every few days when the boy first came under observation last fall, the attack usually beginning about 10 o'clock in the morning by irritability and peevishness, which was speedily followed by a sense of weariness, a chill and finally by the passage of dark, bloody urine. It was remarkable how quickly he would recover even from a severe attack; it was no unusual thing to see him playing around again within an hour

after the subsidence of the attack. The urine was found to be acid and albuminous, but it contained no sugar, and the microscope showed no red blood corpuscles. Hemin crystals could be readily demonstrated by the usual means. The speaker said that only about 20 cases of this disease had been placed on record, and of this number about one-half gave a history of congenital syphilis. Physical exertion and emotional excitement were determining causes of the attacks, and they could be brought on by baths or the immersion of an extremity in cold water. When there was a history of syphilis, antisyphilitic medication would effect rapid improvement. The attacks were most frequent in winter, and from the action of chilling in determining the attack it was obvious that these patients should be warmly clad and kept indoors in cold weather.

Otitis Purulenta Neonatorum et Infantum.

Dr. Max Toeplitz read this paper. He said that the high fever, often associated with stupor or convulsions, occurring in connection with otitis in early life not infrequently led to an erroneous diagnosis of cerebral disease. A positive diagnosis of meningitis could only be made by means of a lumbar puncture. Fortunately otoscopy was not very difficult in children; it was, however, very difficult in very young infants. When meningitis occurred it was the result of an extension of the inflammation through the mastoid-squamous fissure. Primary inflammation of the labyrinth in children was characterized by fever, convulsions, vomiting, dulness of the sensorium, stiffness of the neck and an irregular pulse. Acute otitis was the result of bacterial infection, usually with the *Diplococcus pneumoniæ*, the *Streptococcus pyogenes* or the *Staphylococcus pyogenes*. They gained entrance through the eustachian tube in connection with sneezing or blowing of the nose, or the use of the douche. A child with otitis should be kept quiet in bed, and in the early stages steam and the application of hot water bags were useful, but as soon as there was evidence of pus, the drum of the ear should be freely incised, having first carefully sterilized the ear. The opening in the drum should be in the posterior inferior quadrant. Spontaneous perforation often occurred, but it made an irregular perforation, and the resulting scars were apt to impair the hearing in time. The wiping out of the secretions, followed by dusting with a thin layer of antiseptic powder and the closure of the canal by sterile cotton constituted, in his opinion, the ideal treatment for these cases, but the method was only applicable to cases in which it could be done by the physician himself or by an unusually intelligent and capable attendant. For other cases it would be better to trust to syringing, using irrigations at first every hour, the solution having a temperature of 108 or 110 F.

DISCUSSION.

Dr. E. Gruening said that whoever expected to find on inspecting the ear of a child suffering from acute otitis the circumscribed or the general bulging of the tympanic membrane described in the books, would be disappointed, for, more commonly there would only be a general thickening and obscuring of the usual landmarks. The latter condition was, however, a sufficient indication for paracentesis. This winter he had seen a number of cases of otitis complicated with bronchitis, and he had been impressed with the rapidity of the subsidence of the cough after puncture of the ear drum. For children he favored syringing the ear, using a fountain syringe with the bag only a few inches above the patient's head; for adults, the dry method, already described in the paper, was preferable.

Dr. E. Fridenberg said that he had seen many cases of otitis media in children which had simulated gastroenteric disease. In several instances they had been at first diagnosticated as typhoid fever.

Dr. Charles G. Kerley said that if those who practiced much among children would familiarize themselves with the appearance of the ear in both health and disease they would be less apt to experience the mortification of seeing a case, diagnosed as pneumonia, suddenly lose all of its urgent symptoms on the appearance of a discharge from the ear. For irrigation of the ear he preferred to use a 1 to 10,000 solution of bichlorid of mercury, as often as every three hours for the first day or two. The nasal douche was a prolific source of ear affections.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Pneumonia.

Hooker, in *Med. Summary*, recommends the jacket of absorbent cotton, mustard paste locally for the pain of any accompanying pleurisy, not allowing blistering to take place. This may be followed by a local application of vaselin. In treating a child two years of age he advises the following:

℞.	Quininæ sulph.	gr. xxiv	1.65
	Pulv. opii	gr. ss	0.3
	Ol. theobrom. q. s.		

M. Ft. suppos. No. viii. Sig.: Insert one into the rectum every three hours until the fever abates somewhat, then repeat it three times a day and finally one at night only.

When the foregoing seem to disturb the bowels the following is prescribed:

℞.	Acidi sulph. dil.	gtt. xxx	2
	Quininæ sulph.	gr. xxx	2
	Syr. zingiberis	ʒss	15
	Aquæ q. s. ad	ʒii	60

M. Sig.: One teaspoonful every three hours, diminishing the dose as the child improves, or increasing it if the fever increases.

The following is of value in reducing the fever:

℞.	Ammon. chlor.	gr. viii	0.50
	Tinct. aconiti rad.	m. iv	0.25
	Tinct. opii camph.	m. xv	1
	Syrupi tolutani q. s. ad	ʒii	60

M. Sig.: One teaspoonful every hour for three hours, then every three hours. When the fever is under control the time may be lengthened to once in four hours.

In cases late in the disease if the heart needs stimulation the following is given:

℞.	Ammon. carb.	gr. iv	0.25
	Tinct. digitalis	m. xv	1
	Spts. frumenti	ʒi	30
	Syr. tolutani q. s. ad	ʒiv	120

M. Sig.: One teaspoonful every three hours; or:

℞.	Strychninæ sulph.	gr. i	0.06
	Syr. tolutani q. s. ad	ʒi	30

M. Sig.: Five drops after meals.

As a sequel a lingering cough may be present and under such circumstances the following may be given:

℞.	Creosoti	m. ii	0.12
	Spts. vini gallici	ʒss	15
	Glycerini	ʒii	8
	Syr. tolutani q. s. ad	ʒii	60

M. Sig.: One teaspoonful three times a day to a child one or two years of age.

Insomnia.

The following is an outline of treatment of insomnia due to the various causes as suggested by the *Month. Encyc. of Pract. Med.:* In insomnia from pain, morphin, the coal tar products or large doses of chloral are indicated. Insomnia from reflex irritability, chloral, trional, sulphonal, are the best. When it is due to delirium or chronic insanity, hyoscyamin combined with morphin. And when there is loss of sleep from nervousness and worry the bromids should be given in doses of twenty to thirty grains (1.30-2.00) three or four times daily. One must bear in mind that chloral depresses the medulla and is at times dangerous to the heart, lung, kidneys and stomach.

Internal Hemorrhoids.

Ross, in *Virg. Med. Semi-Monthly*, states that in the treatment of hemorrhoids which protrude at stool and can be pushed back by manual effort, he administers a heaping teaspoonful of

compound senna powder the night before the treatment, to be followed by a glass of bitter water or a tablespoonful of epsom salts before breakfast the next morning. Supplement this by a high enema of normal saline solution before the operation; then cleanse the rectal region under antiseptic precautions. The following solution is then injected into the center of each tumor beginning with the tumor highest up:

℞.	Acidi carbol. (95 per cent.)	℥ii	8
	Glycerini	℥ss	15
	Aquæ destil. q. s. ad	℥ii	60

M. Sig.: Inject as directed.

When each tumor has thus been treated coat the mass with carbolized vaselin and gently push them well up into the bowel.

If much pain is present some opiate may be given. Rest, a light diet and unmoved bowels are enjoined for two days. Then the compound senna powder may be given again at night, followed by the salts in the morning and instruct the patient to avoid straining. The following ointment should then be given night and morning.

℞.	Nosophen	℥i	4
	Cocainæ hyd.	gr. vi	35
	Ext. belladonnæ	gr. iv	25
	Ung. simplicis	℥vii	28

M. Sig.: Apply locally on an applicator introduced well up into the bowel.

The author states that one treatment is generally all that is required.

RECTAL ULCER.

M. G. Price, according to the *Med. Standard*, recommends the following in the treatment of rectal ulcer from whatever cause:

℞.	Ext. hydrastis aqueous	℥iiss	10
	Acidi carbolici	m. xxx	2
	Glycerini	℥ix	36
	Ext. hamamelidis flu.	℥viss	195

M. Sig.: Add to one half a teaspoonful of this mixture an equal quantity of starch and two tablespoonfuls of warm water. Inject into the rectum and advise the patient to retain it over night.

Bedsores.

Palmer, in *Merck's Archives*, recommends a method in the treatment of bedsores due to pressure and atrophic changes aggravated by urine undergoing ammoniacal decomposition: A bag of soft linen is made sufficiently large to extend down the thighs and along the patient's spine. This bag is then filled with bran previously moistened with dilute sulphuric acid. Sufficient bran is used to make an easy cushion. By this method the urine which is constantly dribbling from the patient is absorbed by the bran and the sulphuric acid present neutralizes the ammonia. The proportions advised are about two ounces of sulphuric acid to a quart of bran. This should be renewed every second day. It only makes the bran slightly moist.

Diet in Chronic Endocarditis of Children.

Thompson, in *Pract. Dietetics*, states that children who have chronic valvular disease or enlargement of the heart, but who are not strictly confined to bed, should have their habits of eating closely guarded. They should eat slowly and moderately and at regular intervals, the heavy meal should be at noon, and a light supper two hours before retiring. Animal food is as a rule better for them than vegetables, but they may be allowed fresh vegetables, such as spinach, tomatoes or stewed celery. Rice and macaroni may be given. Bread should be eaten only when dry or toasted. Sweets should be omitted from the list, except very rarely jam or preserves may be given. Sweets are liable to cause flatulency and palpitation and excite the heart's action and produce unnecessary strain.

Aspirin in Diabetes.

R. T. Williamson, according to an article in *Med. Age.*, recommends the use of aspirin in the treatment of glycosuria and diabetes mellitus. This preparation seems to have the most influence in the less severe forms and is less serviceable in the acute forms in young individuals. In order to produce any reduction in the milder forms it should be given in doses of fifteen grains each four or five times a day. The patient should be watched for the appearance of toxic symptoms. It is best to begin with a small dose, ten grains two or three times a day and gradually increase the dose.

Acute Gout.

The following outline of treatment is recommended by the *Cleveland Med. Gazette* in the treatment of acute gout:

℞.	Vini colchici sem.	℥iii	12
	Spts. ammon. arom. q. s. ad	℥ii	60

M. Sig.: One teaspoonful every three hours in water; or:

℞.	Tinct. colchici sem.	m. xx	1 30
	Potass. bicarb.	gr. x	65
	Aq. menth. pip. q. s. ad	℥i	30

M. Sig.: At one dose, to be repeated every three hours; or:

℞.	Ext. colchici rad.	gr. vi	35
	Pulv. ipecac. et opii	gr. xii	70
	Ext. colocynth. co.	gr. xii	70

M. Ft. pilulæ No. xii. Sig.: One pill night and morning; or:

℞.	Ext. colchici rad.	gr. x	65
	Pulv. digitalis		
	Ext. colocynth. co., āā	gr. xx	1 30

M. Ft. pil. No. xx. Sig.: One or two pills to be taken three times a day.

Yeo recommends the following as a remedy in acute gout:

℞.	Tinct. aconiti rad.	℥i	4
	Morphinæ sulph.	gr. ii	12
	Antimonii tartarati	gr. i	06
	Syr. zingiberis	℥ss	15
	Aquæ q. s. ad	℥ii	60

M. Ft. mistura. Sig.: One teaspoonful every three hours in water; or:

℞.	Vini colchici	℥ss	2
	Mag. carb.	gr. xv	1
	Aq. cinnamomi	℥i	30

M. Ft. haustus. Sig.: To be taken at bedtime.

Pericarditis.

The following combination, as noted in *N. Y. Med. Jour.*, is recommended as a local application in relieving the cardiac pain occurring in pericarditis:

℞.	Methyl salicylatis	℥iiss	10
	Menthol	gr. lxxv	5
	Essent. lavendulæ	gtt. xv	1
	Petrolati	℥iiss	10
	Lanolini	℥i	30

M. Sig.: Apply locally.

Earache.

The following combination was first recommended by G. L. Richards in 1898 in the treatment of earache in children. A full presentation of the subject is given in THE JOURNAL, Jan. 24, 1903, page 222:

℞.	Acidi carbol.	m. vii	50
	Ext. opii fluidi	m. vi	35
	Cocainæ		
	Atropinæ sulph., āā	gr. iii	20
	Aquæ	m. lii	3 40
	Gelatin	gr. xviii	1 20
	Glycerin	℥iiss	10

M. Ft. Bougies No. xlii. Sig.: One to be moistened and inserted into the ear.

OTITIS MEDIA PURULENTA.

The following is recommended by N. G. Ward in *Amer. Ther.*:

℞.	Formalin	gtt. v	30
	Alcoholis	℥ii	8
	Aquæ q. s. ad	℥i	30

M. Sig.: To be dropped into ears as occasion demands.

Tinnitus Aurium.

Lewis, in the *Phila. Med. Jour.*, states that the administration of nitroglycerin or the inhalation of amyl nitrite will lessen the ringing in the ears due to anemia and increases that due to hyperemia. In the latter affection the general health should be improved and sedatives given. Hydrobromic acid is of the greatest service and should be administered in fifteen minim doses three times a day, well diluted in water. If the labyrinth is congested pilocarpin is of most value. When the tinnitus is unaccompanied by deafness a solution of strychnia,

gr. 1 to the ounce, should be introduced through the eustachian catheter into the tympanic cavity.

The following combination is advised by Gleason in the catarrhal forms:

℞. Argenti nitratis	gr. 1/4	015·
Ext. hyoscyami	gr. 1/3	020
Strych. sulph.	gr. 1/30	0020

M. Ft. pilula No. i. Sig.: One such after each meal.

Ammonium muriate is recommended in tinnitus of nervous origin. Conium hydrobromate, gr. 1/60 three times a day and tincture of arnica in fifteen minim doses have also been used with success.

Diarrhea in Puerperal Infection.

According to the *Rivista Medica* the following is of service in checking the diarrhea in puerperal infection:

℞. Calcii chloridi	℥ss	2 |
Tinct. opii	gtt. xx	1 | 30
Syr. morphinæ	℥v	20 |
Aquæ lactucarii	℥viii	240 |

M Sig.: One tablespoonful as required.

Medicolegal.

Ten Thousand Dollars for Fracture of Thigh.—In the case of Waldie vs. the Brooklyn Heights Railroad Company, a licensed Sandy Hook pilot met an accident which resulted in a fracture of the thigh, with permanent disablement, and the loss of his occupation, involving the diminution of income to the extent of $125 a month. Under these circumstances, and in view of other recoveries which have been upheld, the Second Appellate Division of the Supreme Court of New York holds that an award of $10,000 damages could not be considered excessive.

Liability of Hospital for Assault on Patient.—The case of Galesburg Sanitarium vs. Jacobson, as it is entitled in the Appellate Court of Illinois, Second District, was brought by the latter party to recover damages from the former, a corporation conducting a hospital, in which he was a patient for some two months, and, he alleged, was assaulted, beaten, mistreated and injured by the servants and employes of the institution. He was ill, the court says, and was a patient residing at the hospital for treatment, and was paying for the services he received, and he was entitled to reasonably kind treatment, so far as the nature of his malady would allow. No assault on him was justifiable, except so far as it was necessary to control him at times when he was insane or delirious. On the occasion in question the servants unnecessarily abused him, and inflicted on him injuries for which the jury were warranted in holding the master responsible. There was no claim that this was a charitable institution, nor any question as to its liability for the negligence of its employes on that account. The fact that the jury awarded but $100 as damages indicated they were not governed by passion or prejudice.

Good Consideration to Support Action for Services.—Several weeks after his daughter, without his knowledge, went to a hospital for medical treatment a father, on learning, through the physician who treated her, about her condition and what the bill for her treatment and board in the pay department was, promised to pay it, but died without doing it. The physician sued the administrator of the father's estate for the amount of the medical services rendered the daughter, and obtained judgment therefor, which the Supreme Court of Mississippi affirms, in the case of Biglane vs. Hicks. It says that there was no evidence on which it could be said that the debt sued for was charged originally to the daughter, so as to bring into the decision of it the question of the statute of frauds, which requires a promise to answer for the debt of another to be in writing. And it holds that if the father was not liable for the services sued for, because they were rendered to a helpless member of his family, who sorely needed them, yet continued service and treatment of the daughter for several weeks by the physician, at the special request of the father, on his promise to pay for the services sued for, as well as for future services, constituted a consideration to support this action.

When "Totally Disabled and Confined to the House."—In Mutual Benefit Association vs. Nancarrow, where the former insured the latter and, it was alleged, promised to pay him a certain sum per week if, from certain causes, he should be totally disabled and confined to the house, the Court of Appeals of Colorado holds that the words "totally disabled," as well as the words "confined to the house," must receive a reasonable interpretation. The purpose of the policy was to indemnify the insured against loss occasioned by inability to attend to his work or business on account of sickness. The total disability contemplated by the instrument did not mean a state of absolute helplessness. The insured might have been able to walk—he might have been able to ride on the car to his physician's office—and still have been entirely incapacitated for work or business. In view of the object of the contract, if he was so incapacitated, he was, the court thinks, totally disabled, within the meaning of the policy. Nor, applying the same rule, does the court think that the words "confined to the house" were intended to mean a constant restraint within doors. One may be sick, it says, and still able to move about and, on occasion, temporarily to pass to the outside. A complete and enforced withdrawal from business or work was undoubtedly necessary, under the policy; but exceptional and temporary absences from the house were not inconsistent with the idea of a general confinement within it. The complaint said that the insured was confined to the house, except at intervals, when he rode on the cars from his house to his physician's office; and, the court thinks, a sufficient confinement was alleged, to answer the requirements of the policy.

Fixing Compensation for Attending Smallpox Patients.—Section 5 of chapter 123 of the Laws of Maine of 1887 provides that the municipal officers "shall regulate and audit all fees and charges of persons employed by each board of health, in the execution of the health laws and of their regulations." In the case of Clement vs. the City of Lewiston, an action brought by a physician to recover for professional services rendered in attending smallpox patients, no specific sum was agreed on for his compensation. He was employed by the secretary of the board of health of the city. The city claimed that it was a condition precedent to the physician's right to maintain the action that the municipal officers had discharged the duty imposed by said section 5, or to show an attempt on his part to have them do so. The presiding justice instructed the jury that if the municipal officers failed to make any regulation or auditing of his account at the time, and there being, when these services were performed, no regulation touching the fees and charges to which he might be entitled, then he was entitled to recover a reasonable compensation. The Supreme Judicial Court of Maine holds that this ruling was correct. It says that the municipal officers could have fixed the fees before the services were rendered, and if they had done so, and it was known to the physician, his rendition of services after that would be regarded as an acceptance of the terms made by the municipal officers, and his right to recover would be limited to that. In the absence of such action by them for any services rendered by the physician under a legal employment the city impliedly promised payment therefor of a reasonable sum. The right to "regulate" fees should be exercised, if at all, before the services are rendered. To "audit" charges in bills rendered does not mean to determine their amount in the sense of binding the other party. To audit is "an examination in general"; "an examination of accounts"; "compare the charges with the vouchers." Webster. On such auditing the bill would be approved or rejected. If rejected, it would not preclude recovery if the physician had a meritorious cause of action. Such auditing can not be regarded as a condition precedent to recovery. The physician's rights did not depend on approval of the municipal officers. This statute gives certain authority to municipal officers and imposes a duty on them, but it is directory. It does not make it the duty of the physician to procure their action before enforcing his claim. Offered evidence of the action of the municipal officers after the physi-

cian's services were rendered, in attempting to fix the amount of his compensation, was rightly excluded. One party to a contract, after performance by the other, can not determine the amount of compensation without the consent of the latter. An offer to prove amounts paid by the city for similar services in previous years was also rightly refused. Such payments might have been on express contracts, or been the result of a controversy or compromise, or have been for services rendered by physicians of small experience or limited skill or reputation, or under peculiar and exceptional conditions. It would be unsafe, and might be unjust, to adopt them as a criterion for the compensation to which the physician suing was entitled.

1 *Notes on Plague as Observed by the Health Authorities of Sydney, New South Wales. G. Frank Lydston.
2 Cases of Intestinal Reaction, with End-to-End Union. C. S. Hamilton and W. D. Hamilton.
3 *The Diagnosis and Treatment of Contracted Pelvis. Warren R. Gilman.
4 *Hypodermoclysis; Experiments, Technic and Clinical Uses. Robert C. Kemp.
5 Medical Organization and the Present Status of the Code of Ethics of the American Medical Association. Charles A. L. Reed.

1. **Plague in Sydney.**—Lydston gives a very interesting account, calling attention to the absence of contagion by fomites, the method of infection through insects and the part borne by rats, which is strongly confirmed by the Sydney experience, the non-contagious character of the bubonic and septicemic forms, and the possible contagion of the pneumococcic type. It is apparently difficult to determine just what ships have brought the plague to port, as rats carry the disease for a considerable period. One animal affects another during the voyage, so that fresh cultures are brought to port. The interesting points are the cerebral toxemia, decline in mortality after the seventh day, speedy death, which is attributed either to the relatively large doses of multiple "bite" inoculations or to individual susceptibility, or to both together, and the trivial nature of the buboes, which seem to be only casual phenomena. Prevention seems to be reduced to simply the prevention of rats from going ashore, frequent fumigation of ships, knowledge of the health of rats in the exposed cities, and the keeping down of their numbers, isolation, general cleaning up, fumigation of infected and suspected premises and the clearing up of plague infection. The prophylaxis of plague is an expensive matter. Sydney has expended as high as $6,000 or more a month in the extermination of rats alone.

3. **Contracted Pelvis.**—Gilman calls attention to the importance of the condition, and gives the generally known facts in regard to the viability of the fetus within certain diameters. In case of slight or moderate contraction, he thinks it is best to leave the patient alone as long as progress is being made. He insists on the practical value of pelvimetry and the low mortality of cesarian section, which is less than 5 per cent. under proper conditions. It should never be performed, however, on an exhausted patient or one exposed to infection.

4. **Hypodermoclysis.**—Kemp has experimented on animals to test the rapidity of absorption and the specific action of normal saline solution on the kidneys, finding that it promotes renal secretion and reduces renal congestion. The technic and indications are given at length. It will be of value in the following conditions:

In diarrheas with excessive loss of fluid, as in dysentery, cholera, cholera morbus, cholera infantum, typhoid and allied diseases; pneumonia, septicemia, pyemia, peritonitis, pyelitis, septic endocarditis, puerperal sepsis, purpura hemorrhagica, severe burns, toxemia due to colon bacillus, tetanus, jaundice, plague, yellow fever, scarlatina, measles, typhus, diabetes, shock; hemorrhage from any cause; as an eliminant in diphtheria, following antitoxin injection; in toxemia of diphtheria, or from any cause; in any coma due to toxemia; in puerperal eclampsia—preceded by venesection; in oliguria, uremia, suppression of urine, renal congestion; in pulmonary edema, pleurisy with effusion, or ascites due to oliguria; in poisoning, as an eliminant, as from carbolic acid, alcohol, opium, carbonic acid gas, and especially in belladonna poisoning. In the last condition frequent catheterization should be employed.

He notices the possible use of hypodermoclysis with sodium salicylate as a diuretic, and the assertion in France that incipient tuberculosis can be diagnosed by means of reactions which occur from this agency. Kemp does not, however, consider this assertion confirmed by his own observations. He thinks it might be useful in toxemias and the high temperature of tuberculosis, but not likely to have any specific effect on the disease. Dr. J. L. Barton has conducted some clinical experiments, as yet unpublished, in which these views are confirmed, and it will probably be worthy of further trial in selected cases as an adjunct to other treatment.

6. **Hand Disinfection.**—McGuire concludes that:

1. Absolute sterility of the hands is impossible by any method.
2. There is no royal road to sterilizing the skin—nothing takes the place of long and vigorous mechanical scrubbing.
3. The longer the hands are scrubbed under aseptic precautions the nearer the approach to sterility.
4. The use of antiseptics on the skin is, at least, questionable; under the usual conditions, it is distinctly harmful.
5. When the true value of antiseptics is understood we will have cleaner hands, due to more conscientious scrubbing.
6. The use of rubber gloves, while not ideal, is the nearest approach to it.
7. The operator whose hands perspire freely ought to wear gloves in every case, regardless of all objections to them.

7. **Chronic Sphenoidal Abscess.**—Somers holds that this condition is not infrequent, but not usually diagnosed. He gives the anatomic data as to the parts involved and the symptoms, noticing particularly the constant nasal and pharyngeal symptoms, pain, ophthalmic symptoms when present, and reports a case. The treatment is outlined, embracing free drainage of the sinus and cleansing of the parts.

9. **Cancer.**—Moak analyzes the Twelfth Census statistics as regards cancer, and finds that cancer and tumor have not increased in any great proportion over several other diseases common in adult life and old age. The geographical distributions correspond almost exactly to that of people of greatest age, and cancer and tumor are, therefore, most frequent in those sections where old people are more numerous.

10. **Nephropexy.**—The method of technic here described by Donaldson is that of Dr. Milbank Johnson of Los Angeles, which is the same as that of the Penrose-Beyea operation until the quadratus is opened, the perirenal fat exposed, the space of Gerotta entered and the kidney separated by blunt dissection from its fatty capsule. Johnson's procedure from this point is:

He makes an incision the length of the kidney through the fatty capsule, the latter being dissected from the kidney but not removed. He then makes four openings about 15 mm. on either side of the main incision. These incisions of course go through skin, fascia, and muscle. The catheter is then passed through the opening, on through the fatty capsule a few millimeters to the side of the main incision in the same, around the kidney proper about 1 cm. from and above the ureter and renal vessels and out through the fatty capsule and the opening on the opposite side. Similarly, a second catheter is introduced through the third opening and brought around below the ureter and vessels of the kidney and out through the fourth opening. The incision in the fatty capsule is then closed and the main muscular incision brought together with continued sutures of catgut and a subcuticular silkworm-gut stitch for the skin. The operator is now ready to manipulate the catheters. There is of course absolute freedom of movement and taking one end in either hand the kidney may be placed in relatively any position toward the abdominal wall which the operator sees fit; in other words, he can get the exact tension on the kidney he desires. Having satisfied himself that the organ is properly placed, the ends of the catheters are clamped together. Emerging as they do from the side of, instead of through the original wound, they tend to draw together the sides of the same instead of forcing them apart as is the case in Penrose's method.

His method of bringing out and fixing the ends of the catheters greatly facilitates the healing and dressing of the wound and comes nearer to the ideal of what the operation of nephropexy should be.

11. **Physical Training.**—Lydston calls attention to the individual equation. Each person should be studied by himself. He notices the differences in the chest form and capacity, the short and thick and the long and shorter muscles and tendons and the different methods of treatment which they require. The evils of athletics are noticed; over-development of muscles and organs often leads them to degenerate from disuse when change in occupation that inevitably follows in many cases is taken up. He thinks the training habit is hard to break; it is as bad as the alcoholic habit in many cases and, while in many instances no particular disaster occurs, there are numerous cases where serious consequences result.

20 *Hyoscin in the Treatment of Morphinism; Its Office and Value. George E. Pettey.
21 *The Scope of Vaginal Section. Egbert H. Grandin.

13. **Hemophilia and Thyroid Extract.**—Fuller reports a case of hemophilia in a boy treated unsuccessfully by other remedies and relieved by 2½ gr. of thyroid extract three times a day. The second case was in a man about 55 years of age, who had hematuria almost constantly from the prostatic sinus, which was also similarly relieved with good results, using 5 gr. doses three times a day.

14. **Hemianopsia.**—Several cases of hemianopsia are reported and discussed by Jackson. Two of them seemed to support the view of Hun, Wilbrand and Henschen, that the upper lip of the calcarine fissure is connected with the upper part of the retina, having to do with the lower quadrants of the field.

15. **Ossiculectomy.**—Dench finds the indications for ossiculectomy in three classes of cases: 1. Those in which the patient is suffering from what is commonly known as chronic non-suppurative otitis media with intact drum membrane, and where operation is undertaken either for the improvement of the function of the organ or for the improvement of certain symptoms, such as subjective noises and vertigo. 2. Those cases in which operation is undertaken primarily for the relief of chronic suppuration, the removal of all dead bone, etc., the main object being to cure the otorrhea. 3. Cases where there has been previous suppuration, but it was so slight as to cause no inconvenience, but the results of the suppurating processes remain, binding down the ossicular chain by adhesions and impairment of function. The paper gives a lengthy discussion on operations.

16. **Appendicitis.**—Jacobson reports cases showing the occasional obscurity of symptoms in appendicitis and emphasizes the fact that we must not depend too much on the so-called nervous symptoms, or be misled by apparently mild constitutional manifestations. Local signs are to be regarded as more significant and reliable. The persistence and aggravation of any manifestation is to be viewed with alarm and suggests progress of the disease. The diagnosis of catarrhal appendicitis, because of the apparently mild symptoms presented, is often unwarranted. The restriction of the inflammatory process to the mucous surface of the appendix without ulcerative destruction is probably rare. True conservatism, if by that we mean the conservation of life, is along surgical and not medical lines in every case of progressing appendicitis. Lastly, every case in which the diagnosis of appendicitis can be made, demands surgical rather than medical care. The question is simply as to when a surgical operation should be performed, and the earlier the better the results.

17. **Typhoid Fever.**—Cook's article gives the general treatment of typhoid. He would keep the patient on a liquid diet. He thoroughly believes in hydrotherapy and that the greatest care should be exercised in returning to the solid diet. Constipation is, he finds, more frequent than the opposite condition. An enema is generally sufficient to relieve it.

19. **Adherent Pericardium.**—Swift thinks that we should be aware that such a condition is not rare, that the great irregularity of action, the patient not appearing as ill as the great irregularity of heart action would indicate, the indraw of intercostal spaces with systole, the marked dyspnea and consequent apprehension, and the great enlargement of the liver, with or without ascites, are important diagnostic signs. In hospital cases the prognosis is bad, but in private practice he has known cases where life has been continued many years. He thinks with proper treatment, abundance of nitrogenous food; arrest of the rheumatic poisoning, we might give a fairly good prognosis.

20. **Hyoscin in Morphinism.**—Pettey advocates the use of hyoscin and criticises Crothers and Mattison, who condemn it. He thinks no remedy is better indicated. It is as important in the treatment of morphinism as chloroform and ether in the practice of surgery. Its office is very similar. It saves the patient from indescribable suffering, and renders the unsafe, impracticable and difficult, safe, practicable and easy.

21. **Vaginal Section.**—Grandin thinks vaginal incision commends itself for diagnosis, palliative treatment and for curative purposes. It is specially indicated in tumors that can be removed through the pelvic brim, but in cases of salpingitis of the right side, with ovarian abscess, especially with adhesions or involvement of the appendages, it is contraindicated. Unruptured and non-adherent ectopic gestation falls within the scope of vaginal section. He does not favor it generally in uterine displacement, which he thinks falls rather outside its scope.

23 *Intestinal Obstruction Below the Ileocecal Junction. (To be continued.) Thomas H. Manley.
24 *The Treatment of Hemorrhoids. John O'Conor.
25 The Use of Cargile Membrane in the Nose in Order to Prevent Adhesions. Harris P. Mosher.
26 Gonorrheal Urethritis without Symptoms. Arthur L. Chute.

22. **Blood Pressure.**—The means of ascertaining blood pressure are described by Jackson, who thinks that anyone who wishes to take the blood pressure should be equipped with a mercury manometer, in the first place, and then have the Riva Rocci armlet and the Gaertner finger ring. With the Riva Rocci the blood pressure should be taken with the patient in the recumbent position, and with the Gaertner method the patient may either lie down or sit up, but the finger should always be on a level with the heart. The patient should be under no mental excitement, which would cause elevation of tension. Two readings at least should always be taken. If they agree, the observation may be considered correct; if there is a marked difference, there has been some mistake, and the test should be repeated. He has used it in testing the effects of bromid of quinin in exophthalmic goiter without seeing any variation of the blood pressure of any account. He has found it of decided value in cases of nephritis and arteriosclerosis as an aid to diagnosis. The blood pressure is normally higher in males than in females. While a pressure of 140 to 150 may be normal for a man, it is abnormal for a woman. Elderly people generally have an elevated pressure, owing to arterial rigidity. Low pressures are not common. It is high pressure we have to deal with principally. A pressure of 200 or more may be considered more or less dangerous, while that of 250 or over is very dangerous, and only seen in grave cases. Higher than these are recorded, but are rare and probably only occur in bad head injuries. He urges all who are teaching or doing clinical work to try this new method of testing the blood tension.

23. **Obstruction of the Large Intestine.**—Manley describes the various forms and sites of the strictures that may occur, such as from malignant disease, syphilis, gonorrhea, etc. Stricture of the large intestine is rarely if ever impermeable,

and it is never sudden or acute in its etiology. It is different from that of the small intestine, as a general rule, depending on intrinsic instead of extrinsic influences. The treatment should not be too radical. There is seldom extreme urgency, as in case of obstruction of the small intestine. He uses measures that will not jeopardize life. Sedatives, local and constitutional, are important. Quicksilver has been employed with success in some cases; hot stupes, kneading the abdominal walls, massage, electrization, etc., in proper cases are valuable. Rectal enemata and instrumental dilatation are the most helpful means of relief in nearly every case, but they should be used with discrimination. A long, stiff rectal tube should be employed, with caution lest serious harm may result. Dilatation of any segment of the large intestine, excepting the rectum, by bougies or sounds is a reckless proceeding, especially in malignant growths, but it may be of value in rectal strictures. Still, he has seen mortal shock follow an attempt at canalization of a scirrhus in a firmly strictured rectum.

24. **Hemorrhoids.**—O'Conor advocates the Whitehead operation, and describes its technic as performed by him.

Medical Record, New York.

27 *Remarks on Achylia Gastrica and Pernicious Anemia. Max Einhorn.
28 *Recent Researches on the Voice. E. W. Scripture.
29 *Doctrine of Survivorship in Case of Two or More Deaths in a Common Disaster. Theodore Sutro.
30 *The Etiology and Prevention of Senile Cataract. J. Wilkinson Jervey.

27. **Achylia Gastrica in Pernicious Anemia.**—Einhorn gives his experience on the possibility of achylia returning to the normal condition, and reports several cases, and on the abrupt development of the condition in pronounced cases of hyperchlorhydria and, after many years' persistence, spontaneous return to the normal state. He gives a tabulated statement of the blood examinations in some 15 cases, several of which have a close resemblance to pernicious anemia, and he discusses the latter condition. His experience is against the assumption that pernicious anemia is caused by atrophy of the stomach, for the following reasons:

1. In most cases of achylia gastrica a nearly normal condition of the blood is found.

2. We occasionally observe the presence of gastric juice in cases of pernicious anemia, sometimes even in an increased amount. If pernicious anemia were caused by an atrophy of the gastric mucous membrane, the achylia would have to be well marked, as soon as the symptoms of the blood disease are apparent.

We can not deny that achylia and pernicious anemia may occur together. These cases are, however, in the minority, and would probably point to the fact that there is a common cause for both affections, or that pernicious anemia finds a ready soil in cases of achylia.

28. **The Voice.**—Scripture describes the methods of taking graphic voice curves and the bearing of the results on the production of tones.

29. **Survivorship.**—The legal question of survivorship is discussed by Sutro, president of the New York Society of Medical Jurisprudence. It was suggested by the recent Fair case in France, which has been before the French and California courts. He holds the presumptions of the Roman law, based as they are entirely on age and sex, and likewise the statutory presumptions in vogue in some countries of simultaneous death, appear neither of them to rest on any logical foundation. The most reasonable and logical rule, he says, would seem to be one which has been most generally adopted in our law, namely, that when it is necessary or important to ascertain or consider which of several persons survived, and there is no evidence, no presumption whatever will be indulged in, but the conclusion adopted that all perished simultaneously.

30. **Senile Cataract.**—Jervey discusses the prophylaxis of senile cataract, and sums up that:

Many cases of cataract, especially of the senile form, are started and aggravated in their progress by the friction of a ceaselessly moving iris, which has been roughened, hardened, stiffened, thickened, by disease. Many of these cases can be arrested, or their advance indefinitely postponed or prolonged, chiefly by the careful performance of the simple little operation of sphincterectomy.

34 *Is Nephroptosis Hereditary? John G. Sheldon.
35 A Case of Trigeminal Neuralgia Complicating Typhoid Fever. Charles J. Aldrich.
36 *The Toxemia of Pregnancy. William H. Wells.

31. **Tropical Diseases.**—This sixth lecture by Kieffer deals with the prophylaxis and treatment of tropical dysentery. The first indication is removal of the etiologic factor, destruction of the ameba and elimination of intestinal bacteria by the remedies mentioned, such as silver nitrate, etc. He adds protargol to the list. Next comes the relief of the chronic liver congestion, and here he advises draining by purgation, noticing the saline sulphates as useful. Alcohol should be prohibited, and the meat diet restricted. Counter-irritation by dry heat or poultice may be employed for the liver engorgement and in severe cases hepatic phlebotomy is indicated. When active dysentery is present the use of ipecac as in acute dysentery may have a marked effect, as well as quinin where malaria is present. Explorations for suspected pus must be frequent and searching, and the details are described, as well as that of the operation by incision. Rigid asepsis, of course, must be employed. Kieffer disagrees with the advice to scrape the abscess wall and, ordinarily, would not wash out the abscess. If the sac be very large, making a counter opening necessary, then washing of the sac is safe. If, after operation, amelioration of symptoms does not ensue, the conclusion is forced on us that another focus has formed that must be searched for. Similarly in cases where rupture has taken place, into the lung or bowel, and the symptoms continue, an attempt must be made to evacuate the cavity through the skin.

32. **Surgery of the Biliary Passages.**—Deaver's article is a general description and discussion of the conditions of biliary surgical disease.

34. **Nephroptosis.**—The question whether nephroptosis is inherited is raised by Sheldon. He gives an account of a family in which five members were thus affected, all females. None of the other members of the family were examined. He thinks the condition occurs more often in children than is suspected, and reports a case where it was found, producing unfavorable symptoms, relieved by operation.

36. **Toxemia of Pregnancy.**—Wells' article is concluded in this issue. He discusses the diagnosis, which is made from the symptoms and the amount of solids and urea excreted. Albumin alone is not sufficient for the diagnosis. The symptoms may somewhat resemble hysteria, and hysteria may be caused by toxemia. Occasionally they may simulate acute indigestion and sometimes miscarriage. In the majority of cases the prognosis is good provided the patient is under a physician's care and disease of the liver and kidneys is absent. He would say that the prognosis for a pregnant woman whose excretions were faulty, was only good in so far as she followed out the advice of the attending physician. The most important point in treatment is to increase the elimination by the bowels, kidneys, liver and skin. He would cut off the meat diet in most patients, giving a moderate amount of nutritious food; fruits, vegetables rich in starch may be allowed, but sandwiches and stimulating diet, coffee and tea are prohibited as a rule. Malt liquors are bad; the least harmful, if alcoholic beverages are insisted on, are the dry Rhine wines. The clothing should be such as to increase elimination by the skin. A suitable amount of outdoor exercise, taken short of fatigue, and the free ingestion of water, to increase the action of the kidneys, are advised. The patient should take at least a full glass of Buffalo or Londonderry lithia or apollinaris or some carbonated water before each meal, at bedtime and on rising in the morning. The laxative waters serve a double purpose, but their taste is objectionable to many persons. Sweet spirits of niter may be given, and in severe cases of toxemia with high pulse tension, he would give some cardiac depressant like veratrum viride, or if syncope or cardiac irritability is present, digitalis either alone or with small doses of nitroglycerin, will give good results. He

speaks particularly of calomel as an eliminative and the use of a cathartic, preferably the salines, keeping up the laxative for a number of days until the patient has had a sufficient number of profuse watery stools. Bowel irrigations and lavage are also required in some cases.

February 10.

44 *Chronic Proctitis. J. A. MacMillan.
45 Acetozone in Typhoid. John F. Bennett.
46 *Some Habits of Malaria not Controlled by the Mosquito. Charles Hicks.

44. **Chronic Proctitis.**—MacMillan thinks that in many cases of constipation or diarrhea where the cause is not readily found, a thorough rectal examination should be made. Acrid or drastic cathartics produce much irritation and congestion of the rectal mucous membrane, especially in cases of chronic proctitis, and should be restricted in their use and saline cathartics substituted. Physical exercise in certain cases of constipation is harmful. Straining at stool is particularly injurious where there is hypertrophy of the rectal membrane. A temporary prolapsus is produced and this causes occlusion.

46. **Malaria.**—This article of Hicks is an interesting study of medical geography. He points out that a certain region over the cretaceous formation in Georgia is the special home of hemoglobinuria, which is absent from the surrounding country. He attributes this hypothetically to the bad drinking water in this region. The estivo-autumnal parasite is found in both sections. He suggests also a certain connection between the diet and malaria.

47 *On the Relations between Human and Bovine Tuberculosis. P. von Baumgarten.
48 *The Cinnamic Acid (Hetol) Treatment of Tuberculosis. A. Landerer.
49 The Urinary Calcium Excretion in Tuberculosis. Alfred C. Croftan.
50 *The Early Diagnosis of Tuberculous Laryngitis. Richmond McKinney.
51 *Methylene Blue in Consumption. Henry Herbert.
52 *Tuberculosis of the Cervical Lymph Glands. Daniel Eisendrath.

47. **Human and Bovine Tuberculosis.**—Professor von Baumgarten agrees with Koch in the non-identity of these two conditions in all respects. He is convinced that the tuberculous human subject is the principal if not the sole source of infection of others. He does not, however, fully agree with Koch that the sputum is the sole source of infection, and thinks the ingestion of tuberculous food has more or less to do with it. He lays special stress on heredity.

48. **Cinnamic Acid in the Treatment of Tuberculosis.**—Landerer, the originator of this method of treatment, gives his views and experience. He finds in the early cases about 90 per cent. of cures. In the more advanced cases, the weaker the patient the smaller the dose that should be given, continued over long periods. Cases are reported. In no other form than pulmonary tuberculosis does the method yield such good results. Laryngeal tuberculosis, so long as it is isolated, that is, not associated with extensive changes in the lungs, offers a good prognosis, but is unfavorable if it occurs late in connection with extensive pulmonary involvement. Patients with laryngeal tuberculosis require large doses, 20 to 25 mg. Intestinal tuberculosis is a favorable field, even if fever is present. It must be remembered, however, that during treatment signs of intestinal stenosis may appear. In renal tuberculosis the tubercles undergo cicatricial changes, but no effect is seen on co-existing purulent catarrh; therefore the clinical results are negative. Simple tuberculosis of the bladder yields a somewhat better prognosis, and very good results and permanent cures have been obtained in tuberculosis of the epididymis and vas deferens. The glands and scrofulous processes yield mostly favorable results, though sometimes they are tedious and require long treatment. The suppurating gland should be curetted and dusted with hetokresol (cinnamyl metakresol) and be drained. Surgical tuberculosis also gives a good prognosis. The suppuration is not influenced, however. Tuberculous wounds heal rapidly when dusted with hetokresol. Skin tuberculosis yields nicely to cutaneous injections of an alcohol solution of cinnamic acid, 1 part in 19. Treatment, however, is tedious. No good results have been obtained in brain tuberculosis.

50. **Tuberculous Laryngitis.**—A safe general rule, according to McKinney, is that when there is a persistent laryngeal catarrh with evidence of hoarseness not yielding to the ordinary measures, it should be regarded with suspicion and the case closely investigated and the lungs minutely examined. A peculiar sticking sensation in the region of the larynx is another constant symptom in the early stage. There are, of course, other conditions that may have identical symptoms, and syphilitic infection should be borne in mind and potassium iodid administered.

51. **Methylene Blue in Consumption.**—Herbert finds methylene blue of no special advantage in consumption; but it may relieve the cough and reduce expectoration. It is contraindicated in sensitive or hectic cases.

52. **Tuberculous Glands.**—Eisendrath points out the special diagnostic features of conditions that may be confounded with tuberculosis, such as Hodgkin's disease, syphilis, epithelioma, etc. He thinks the treatment should be a radical one. The only exceptions are in children and in others where operation is not proper on account of slight gland involvement, and where family inheritance shows a strong tuberculous tendency and there are suspicious signs in the lungs. It is also inadvisable in much debilitated anemic children, especially if complicated with chronic bronchitis. External applications, especially iodin, do more harm than good.

Interstate Medical Journal, St. Louis.

54 *Operations for Cancer of the Mouth and Neck. G. W. Crile.
55 A New Surgical Table. Bransford Lewis.
56 Address of Welcome to Professor Lorenz. H. Augustus Wilson.

53. **Formalin in Septicemia.**—Elbrecht and Snodgrass have experimented on the effects of formalin in the blood on the metabolism of normal animals, and also of those in which septic infection exists. They have found that normal rabbits can bear formalin dilution of 1 to 500 when given in doses porportional to a liter in man, but in later experiments they have used a weaker dilution, 1 to 2000 to 1 to 5000, which is

safer. Thus far they have had two apparent recoveries as a result of this treatment. One rabbit, however, died later when, according to temperature records, he had become convalescent. The other has since become normal. Thus far they have injected 13 rabbits with formalin ranging in strength from 1 to 5000 to 1 to 500. With the exception of 3 which were killed for examination and 1 that died, the other 9 are living and in apparently normal condition. Four streptococcus infected rabbits were treated with normal saline solution, 2 died, 1 is apparently passing into a state of recovery, the other, being immune, was not treated. Two streptococcus rabbits were treated with 1/5000 dilution of formalin in normal saline solution; both died. Two rabbits similarly infected were allowed to go untreated, and both died on the second day, showing the culture to have been intensely virulent. Three streptococcus rabbits were treated with a 1/2000 dilation of formalin in water, and 2 recovered, 1 died. The third was allowed to go untreated and died in thirty-six hours. They do not attempt to draw conclusions from this limited number of experiments, but simply offer them for what they are worth.

57 *The Prognosis of Tuberculous Peritonitis in Children. G. A. Sutherland.
58 *The Effects of Tight Diapers. A. C. Cotton.
59 Two Instructive Cases of Cerebral Pneumonia and Their Treatment. Louis Fischer.
60 *Pilocarpin in the Treatment of Scarlet Fever. E. W. Saunders.
61 A Case of Paroxysmal Hemoglobinuria in a Boy Four Years Old. Charles Herrman.

57. Tuberculous Peritonitis.—Sutherland finds that uncomplicated tuberculous peritonitis generally has a good prognosis, even when tuberculous pleurisy is present. It is less favorable when there is a strong family history of tuberculosis; an infancy passed under bad hygienic and dietetic conditions; a constitution of feeble resistant power or a history of severe infective illness in early life. Certain conditions or symptoms render it less favorable, such as continued pyrexia, rapid wasting, persistent diarrhea, rapid pulse, or recurrent acute exacerbations. It is also rendered less favorable in the presence of one or more of the following local complications: Tuberculous ulceration of the bowel; extensive caseation of the mesenteric lymph nodes, or of tuberculous masses; localized suppuration from infection through the lymph nodes or the intestine; obstructive symptoms from bands or matting of the intestine. It is bad in cases of rupture of the suppurating lymph node, or the perforation of an intestinal ulcer into the peritoneal cavity, in tuberculous meningitis and general miliary tuberculosis. In tuberculous peritonitis the prognosis is not appreciably affected by simple laparotomy.

58. Tight Diapers.—Cotton thinks the use of tight diapers on infants is likely to produce the justo-minor pelvis in the adult and that much of this prevalent deformity is due to just this cause. He suggests some care as to this point and better hygienic clothing. The ideal protection would seem to be afforded by a large blanket of light, flexible, non-conducting material enveloping loosely the entire infant below the neck, but it is hard to keep him inside such a garment as this. He mentions a bag-like garment that is now in use in some of the hospitals of Chicago and other cities.

60. Pilocarpin in Scarlet Fever.—The use of this remedy in scarlet fever is advocated by Saunders, who finds its benefit is due to its effect on the salivary and muciparous glands, with the absence of all tendency to myocardial or neural degeneration and of pulmonary complications. In hyperpyrexia hydrotherapeutic measures are the first to be used, followed by the administration of pilocarpin; even at ordinary temperatures, such as 104, it is better to precede each dose by a thermolytic bath. The first dose should be watched for idiosyncrasy, and if this is present a hypodermic of atropin will prevent disagreeable consequences. Subsequent doses should be graduated according to the effect of the first and the height of the temperature. Toleration is rapidly established. A parched mouth, however, should never be allowed during the disease.

66 The Erotopath in Society. Charles H. Hughes.
67 The Suggestive Treatment of Hysteria Gravis. V. Krafft-Ebing.
68 The Evolution of the Neuraxis. Charles H. Hughes.

62. Hemorrhagic Internal Pachymeningitis in the Insane.—Courtney finds this condition more or less pronounced in nearly 10 per cent. of all cases, and concludes that it is peculiarly associated with insanity, especially with paresis, alcoholism and dementia. It is twice as common in men as in women. It consists in hemorrhage and partial absorption and organization of the effused blood, forming a membrane.

63. Neurology and Surgery.—Hughes emphasizes the relations that exist between neurology and surgery, the actions of the neurons and attention to nutrition and conservation of these organs, also the psychiatric element in surgery. He thinks the surgeon should avoid all sources of psychic depression and consider the nervous symptoms of his patient before and after operation to ensure success. The possibilities of post-operative insanity are noted.

Journal of Cutaneous Diseases, New York.

69 *The Histogenesis of Scales and Crusts. R. Sabouraud.
70 *Note on the Histology of Herpes Zoster. S. Pollitzer.
71 *The Value of Radiotherapy in Cutaneous and Other Cancers. Charles W. Allen.

69. Scales and Crusts.—In this article Sabouraud analyzes the origin of scales and crusts, which he finds is not exactly in accordance with popular notions, but he wishes to show that among the processes which go to make the scale of the usual histologic type, that is, the scale-crust, the process of hyperkeratosis is a reactional phenomenon of the second order. The two processes which form this scale and this crust are the exhalation at the surface of the skin of a serous "tide" and of a leucocytic "scum." These are the first two phenomena. As to the hyperkeratosis which covers the scale-crust with a corneous layer, it is a secondary reaction of the epidermis to the exoserosis and exocytosis, once they are produced. These two phenomena of exoserosis and of exocytosis dominate the formation of the scale in general as well as all crusts, excepting only the simple pityriasis capitis and of ichthyosis, which are exclusively produced by hyperkeratosis.

70. Herpes Zoster.—Pollitzer's article gives an instance which proves the occurrence of a variety of herpes affecting the rete Malpighii or hair follicles exclusively, a type that has not been heretofore described.

71. Radiotherapy.—While recognizing that the *x*-ray as a therapeutic measure is not a passing fad, Allen points out that its effect is at times to produce severe harmful symptoms referable to the heart, lungs and other internal organs, and absorption of disintegration products. Metastases may be encouraged and cancer itself may be produced in predisposed individuals. The method is not to be solely relied on in all cases of cancer. In the nodular, wart-like and dry growths on the skin, other means of removal, preferably by arsenical paste, should first be employed and the rays may then be applied. The indiscriminate application of the ray to all forms of disease as practiced by unscrupulous advertisers and quacks and the deceit practiced by calling other rays by this name, are likely to bring discredit on a method really useful whose effect is at times almost magical but often most disappointing.

72 A Study of Tuberculosis in Cleveland. William T. Howard, Jr.
73 *The Frequency, Site and Course of Tuberculosis in Cleveland. John C. Darby and Henry P. Parker.
74 *On the Nativity of Decedents from Tuberculosis in Cleveland for the Years 1895 to 1901. Cullen F. Welty.
75 *On the Relation of Age, Sex and Conjugal Condition to Deaths from Tuberculosis. George W. Moorehouse.
76 *The Distribution of Tuberculosis in Cleveland. Wm. O. Osborn and Frederick C. Herrick.
77 Municipal Prophylaxis. Martin Friedrich.

73. **Tuberculosis in Cleveland.**—The statistics of the prevalence of tuberculosis in Cleveland, as shown by a record of 658 autopsies, are discussed by Darby and Parker, who conclude that their figures of 29.6 per cent. of definite tuberculosis at autopsy falls considerably below the true figure, and would include their 5¾ per cent. of cases of apical adhesions, making a total of 35.5 per cent., or one-third of all autopsies showing tuberculous change. This they consider a very conservative estimate. Active tuberculous processes were found in practically one-half of all cases showing definite tuberculosis. In half of these cases it was the cause of death. Under 20 years of age active tuberculosis is almost always fatal, but later steadily decreases, so that death from tuberculosis is comparatively rare in persons over 60 years of age. The relative frequency of tuberculosis of the principal organs is, in order, as follows: lungs, bronchial glands, spleen, intestines, kidneys, liver and nervous system. The other portions of the body are rarely affected. The primary focus is almost invariably the lungs and occasionally the bronchial glands.

74. **Nativity of Tuberculosis Cases in Cleveland.**—Welty has analyzed over 3,000 deaths from this cause in Cleveland, and finds that only 730 of the individuals were born there; 1,203 were born elsewhere in the United States, and 1,306 foreign born. This gives 119 deaths to each 100,000 of the native-born population and 151 deaths to 100,000 of the foreign-born population, with a general mortality of 130 to each 100,000 of the total living population. He gives a comparative table from other sources of the deaths from tuberculosis in the various European countries, showing that the mortality from tuberculosis in those mentioned is in all cases higher than that of the Cleveland residents born in those countries. The Irish seem to have profited the least by change of residence and the Hungarians most.

75. **Age, Sex and Conjugal Condition in Tuberculosis.**—From a study of the Cleveland statistics in regard to these points, Moorehouse finds that the city furnished during the seven years from 1895 to 1901, inclusive, 8.7 per cent. of its total deaths from tuberculosis. It was the cause of 1.4 per cent. of deaths between the ages of 20 and 25 years and 2.6 per cent. of deaths between 20 and 30 years; 15.5 per cent. were from tuberculosis between 20 and 25; 30.3 per cent. between 20 and 30 years, and 50 per cent. between 23½ and 44 years; 4.9 per cent. of all male deaths were from this cause. The male deaths dominated over the female, in whom over 3.8 per cent. of all deaths were from tuberculosis. The greatest number of male deaths was found between the ages of 25 and 29, of females between 20 and 24. In proportion to the living population the greatest number of deaths occurred between 55 and 64 years. He does not find it easy to settle on the actual relations of marriage with liability to death from tuberculosis. The real relation that he finds exists between tuberculosis and marriage is that the condition under consideration has a very marked tendency to postpone or prevent individuals so affected from marrying.

76. **Distribution of Tuberculosis.**—The localities specially affected by tuberculosis in Cleveland are noted by Osborn and Herrick, who find that certain districts show much greater mortality than others, these occurring mostly in the older parts of the city, near the manufacturing and railroad districts and in those occupied by the laboring classes. They think it is due to the unsanitary conditions in which these people work and live; their ignorance or indifference to minor ailments, especially the early signs of tuberculosis. They do not find any considerable number of house infections.

Physician and Surgeon, Detroit, Mich.

November, 1902.

77½ *The Iliac Segment of the Ureter. Byron Robinson.
78 *Joys and Sorrows of an X-ray Worker. Henry Hulst.
79 *The Therapeutic Value of Echinacea in Septic Conditions. Frank D. Walsh.

77½. **The Anatomy of the Ureter.**—Robinson's article is an elaborately detailed anatomic description.

78. **The X-Ray.**—Hulst gives his experience with the use of the *x*-rays. He has found the induction coil most satisfactory to him for instantaneous work, and he points out the importance of the operator doing all his work, even to the development of his plates, to get the best results.

79. **Echinacea.**—This drug is recommended by Walsh as a valuable remedy for blood deprivation and an active antagonist to septic changes. He has found it of value in puerperal septicemia and other septic conditions, in gangrene of the lung, etc. There are two preparations, the normal tincture and the "echafolta," the latter being the name given to a purified form of echinacea of a definite strength.

83 *Mouth Infection Due to Natural Teeth. D. D. Smith.

83. **Mouth Infection.**—Smith notices the particular increase of dental disease, which, he thinks, has much to do with the general health. The kidneys, he holds, are specially affected in pyorrhea, and he says that every mouth with teeth in the natural state untreated is constantly breathing out infection. The contention, therefore, over the surgeon's beard seems puerile. It would be better for antiseptic purposes if it was an absolutely complete mouth mask. He finds from his experimental work that caries is the result of environmental conditions. His method of treatment is complete removal of all concretions, calcic deposits, semisolids, bacterial placques or inspissations of the teeth between them and the gum margin, and frequent polishing of the teeth by hand methods; not alone the more exposed labial and buccal surfaces, but the lingual, palatal and proximal surfaces, as well, of the mouth are thus treated. With this "mouthly prophylaxis" he has been able to stop decay and finds decided benefit in many conditions, such as general malaise, nervousness, nervous prostration, nervous dyspepsia, etc.

84.—See abstract in THE JOURNAL, xxxix, p. 329.

86. **Biliary Acids.**—Spivak discusses the Hay test for bile acids in the urine, giving its history. He has applied this test to the study of bile acids in the feces and stomach contents. The more he studies it the more striking it seems. A pinch of flowers of sulphur thrown on water or bile-free urine will float for weeks on the surface. On the addition, however, of one drop of bile to a quart of water, it will at once sink to the bottom. The test is so different in its nature from all other known means of analysis and so extreme in its sensitiveness that it is almost miraculous. Acetic acid, alcohol, ether, chloroform, essence of turpentine, benzoin and its derivatives, phenol and its derivatives, and anilin also cause the sulphur to precipitate. All fluids with a surface tension above 50 dynes per centimeter do not allow sulphur to fall, and in all fluids with a tension less than 50 dynes the sulphur rapidly settles. Lycopodium has the same relation to fluids with a tension of 30 dynes as flowers of sulphur to fluids with a tension of 50 dynes. In his own experiments he has noted that the specific gravity of the fluid has no influence on the accuracy of the test, nor has the reaction of the fluid any effect on the test. The fluid must be clear for correct results and the urine free from bubbles. Urine examined immediately after it is voided gives, invariably, the reaction for bile. This annoyed him until he found that heat reduced surface tension, and it must, therefore, be cooled off. His experiments have not yet warranted him to make positive assertions, but he wishes to call attention to this test for bile acids, which, with its simplicity, accuracy, and sensitiveness, should have universal application.

1. **Adenoids of the Rectum.**—Ball's first lecture describes simple, multiple and congenital adenoma. By the word adenoma, we understand a tumor largely composed of epithelial tissue such as found in the gland structure. If it is a simple surface development, we speak of it as simple adenoma. If it grows through the basement membrane, invades the submucosa and infiltrates the tissue outside, the case is one of infiltrated adenoma or adenocarcinoma, the true form of intestinal cancer. This penetration of the submucosa is a characteristic distinction between the malignant and benign forms of the growth. First the adenoma appears as a wart-like congestion on the mucous membrane, which soon becomes more and more prominent while its base is narrowed to a peduncle, which tends to elongate so that it may project into the anus. These are sometimes single, but often multiple, and they cover extensive tracts of the mucous membrane. In this connection Ball mentions the congenital type, for which he favors the theory of its origin as failure of complete obliteration in one or other of the neurenteric canal or post-anal gut. The surgical treatment of these cases of embryonic adenomata, except when very small and extrapelvic, is not satisfactory. Symptoms of simple adenoma of the rectum are trivial unless the growth becomes protruded through the anus and becomes congested, causing bleeding. Another symptom is the discharge of glairy mucus, causing considerable discomfort and showing that the tissue still remains functional. Sometimes they undergo spontaneous cure, the pedicle sloughing off. The treatment consists in removal of the pedunculated forms after ligature of the pedicle and, when this is at all broad and strap-like, it is a good plan to transfix and ligature it in sections; the sessile varieties, especially if there is any tendency to infiltration, are best excised. When a considerable area is covered by villous growths they may be removed by the curette as are venereal warts.

3. **Shellfish Pollution.**—Klein describes at length the different types of bacterial pollution of shellfish, and he thinks that the mere chance of pollution may be considered unimportant,

but when the oysters are laid down where they are actually flooded by crude sewage in their immediate neighborhood, the danger is considerable. Oysters, moreover, even when they imbibe the *Bacillus typhosus*, discard it again when placed in clean sea water after ten or fourteen days, while cockles retain it, and even become a culture ground for it. The three forms especially noted are the *Bacillus coli*, the *Bacillus enteritidis*, and the *Bacillus typhosus*. The characteristic distinctions of the three groups are noted. Though there are many other of the colon group which may appear, their relation to sewage and pollution is not sufficiently known and, therefore, they can not be used for diagnostic purposes as can the *Bacillus coli*. The tests of the colon or the Gärtner or the typhosus group must be made to prove that they are characteristic of one or the other of these. When a microbe can only be described as a coli-like microbe, it is of indeterminate value in making a definite diagnosis of sewage and other pollution. The presence of *Bacillus coli communis* in any material quantity is highly suggestive of sewage or excremental pollution. The typical *Bacillus coli* is not a natural inhabitant of the oyster. The methods of the tests are described. Klein also holds that the presence of spores of the *Bacillus (enteritidis) sporogenes* alone, without the simultaneous presence of *Bacillus coli communis*, can not be held as sufficient proof that the oysters have been subjected to recent sewage pollution, but when they are found together the evidence is strong.

5. **Rupture of the Aortic Valves.**—The question as to whether rupture of an aortic valve is an accident coming under the English workmen's compensation act is discussed by Fisher, who notices the facts as shown in the pathologic literature and concludes that disease of the aortic valves may be the result of untreated syphilis or some other infection, but, of whatever cause, it seems clear that rupture of the aortic valve segment is, in the majority of cases, the result of the same disease as that which produces aneurism of the aorta.

7. **Picric Acid.**—Milward finds picric acid specially useful in some minor conditions other than burns. In slight eczematous conditions with "weeping" surface and in slight traumatic abrasions it may be useful. It is not advisable to use it in active inflammation, as it may confine micro-organisms under the protective coating it produces. He mentions, among the affections where it is useful, paronychia affecting the roots of the nails, common in surgeons and practitioners, ingrowing toe nails, soft corns, intertrigo, etc. It is better than starch and zinc oxid for those conditions, as these latter are likely to form crusts in which pus may form. It does not seem to cause irritation of the tissues like other antiseptics.

9. **Skin Inflammations.**—Crocker notices the various forms of dermatitis, those from irritation, various trade eczemas, etc. As to the question whether eczema is parasitic, a blood dyscrasia or a neurosis, no absolute answer can be given. But when the process is started, pus cocci, either staphylococcic or streptococcic, are present and do modify the form of inflammation and, in a large number of these cases, we should realize this fact, and consider whether we must not attack these organisms to successfully treat the condition. He mentions pemphigus—especially neonatorum, fungating papillary growths, and considers seborrhea at considerable length. In conclusion, he mentions the local origin of certain general eruptions, especially pityriasis rosea, which is not infrequent, but is not usually known except by the dermatologist. It generally consists first in a single patch, followed later by a widespread asymmetrical outbreak, which, after lasting for three or four weeks, gradually disappears. He has also seen similar local originations of psoriasis. The most feasible explanation is the invasion of the micro-organism from without and the local multiplication or, perhaps, the formation of toxins internally, with absorption into the circulation and generalization from within outward. We should attempt to treat the diseases in their beginnings, to prevent their later extension.

10. **Fibroids.**—In this third lecture, Doran begins with the management of capsules. Usually there is little need for trimming, as the tissue usually shrinks. Vessels have to be secured on the inner or parametric surface. As to the question whether they can be let alone or drained, there is some difference of opinion. He is inclined to hold that drainage is oftener necessary than some authorities would recognize when the capsule is deep. There are objections, but the practice is underrated at the present time, as it was formerly overrated and abused. He is not an enthusiast for it, but simply wishes to speak of its advisability in certain cases. Adhesions are rare in uterine fibroids, and seem to be sometimes connected with previous operative interference. He says it is important, however, to remember their infrequency. Small uterine adhesions in case of large ovarian cyst are a distinct source of danger. In case of dense adhesion of the ileum it is often better to resect an adherent piece of the intestine. Intestinal adhesions to malignant ovarian tumors are especially perilous, but they are rare in uterine fibroid disease. This fact should be considered in estimating the risks of hysterectomy. There is the possibility of adhesion of the extraperitoneal part of the large intestine to the surface of the tumor, which burrows under and behind the pelvic peritoneum, as in case of rectal adhesions. This is not always easy to recognize, and longitudinal bands may be taken for the ureter or may be taken for strands of fibrous tissue belonging to the tumor. After dividing the pelvic peritoneum, too rapid or rough use of the sponge or the finger may result in damage to the rectum, and that portion of the intestine has been known to be torn by too energetic pulling up of the tumor out of the pelvis. Parietal adhesions are very rare, for what appears to be such are more likely to be a direct connection between the abdominal parietes and the tumor. The fibroid burrows under the anterior layer of the mesometrium. Adhesions of fat omentum associated with a big omental epiplocele are very dangerous. The possibility of post-operative ileus and of rupture or hernia of the abdominal wound are considered and instances given. He thinks there are no reliable statistics on this subject, but that the more experienced operators have the least trouble. Still, no one can be sure of avoiding it. The possibility of cancer of the stump and the management of it is discussed at length. He notices, particularly, the discussion in the American Gynecological Society on the advantages of complete and partial hysterectomy as regards the retention of more or less of the stump of the cervix. He asks, may not any method of operating devised to maintain the nutrition of the stump favor the development of cancer, such, for example, as preservation of the ovaries, etc.; but admits we have not facts to answer this question. In conclusion he speaks of the danger of pushing a fibroid out of the pelvis, which is especially dangerous during pregnancy.

11. **Appendicitis.**—MacDougall first notices the comparative rarity of appendicitis in former years and its frequency at the present time, and gives statistical data in support of this latter assumption. He is inclined to consider the disease an increasing one, and its severity is becoming greater. The increased frequency of relapse is another point of interest. As a rule the acuter the initial symptoms the greater the gravity of the case. He lays special stress on the character of the pulse rather than its rapidity. A quick small pulse, with a high, or worse still, with a low temperature, should attract immediate attention and the pulse and the temperature should be closely watched. Sometimes a normal temperature with

quickening pulse may tell the true story. A pulse of 120 should be regarded as a very ominous sign. He also cautions against regarding the "period of repose" which may occur and may lead to serious error. It is possible to misread the phenomena that indicate lethal appendicitis, striking as they are. Colic of the appendix is one confusing condition, and he gives an instance. Renal and hepatic colic have proven sources of error, and intestinal obstruction may appear to be the condition when real ultra-acute appendicitis exists. Disease of the right adnexa is also noted here. The cecum itself may give cause to symptoms which we may credit to the appendix. He has no present knowledge of the simulation of lethal appendicitis by gastric or duodenal ulcer or twisting of the pedicle of an ovarian cyst, but records show how strong the counterfeit may be. Text-books say little about the difficulty of differentiating between appendicitis and typhoid fever, though it is a notable problem. A condition difficult of explanation yet not of recognition, occurring in many abdominal troubles, may, when appearing with the appendix as its exciting cause, lead us astray, that is peritonism. It is extraordinarily like peritonitis, and yet the importance and the gravity of the one are occasionally only mimicked by the other. The lack of tenderness of the swollen abdomen is one differentiating point, and often there is a certain quickness of pulse and rise of temperature; the freedom with which the patient moves and breathes and the expression of the face also suggest deception. A basal pleurisy or pneumonia involving, as they are apt to do, the pleural surface of the diaphragm, may lead to symptoms that suggest acute peritoneal inflammation. As regards treatment, he has not much to say. He thinks opium should be avoided, but it may be absolutely necessary. It is better given by suppository or rectal injection than as morphin subcutaneously. Enemas rather than aperients by the mouth should be used if needed. Early operation is safest. He would make an incision closer to the anterior superior spine of the ileum than is usually advised. It is quite possible to display and remove the appendix without any protrusion of the small intestine, and in cleansing and drainage of the inflammatory area and its surroundings he has more belief in the use of sponges and swabs than in irrigation, and in large sized drainage tubes with gauze wicks than in gauze packing. He bears testimony to the extreme value of normal saline solution subcutaneously in septic conditions.

12. **Trypanosoma in Man.**—Priority in the discovery of trypanosoma in man is discussed by Boyce, Ross and Sherrington, who conclude that, whatever the claims of others may be, it was certainly Dr. J. S. Dutton (Thompson-Yates Laboratory Reports, 1902) who first established the existence of trypanosomes in human beings in a thoroughly scientific manner.

26. **Abortion of Syphilis by Intravenous Mercurial Injections.**—Tommasoli has been using the intravenous route during the last seven years for the abortion of syphilis, instead of using it as others have recommended, merely as a last resort. He has thus treated 44 patients, restricting this method of treatment to cases in which the initial syphiloma was diagnosed beyond question, and in which the infection had been contracted less than forty-five days previously. The longer the interval since infection the more energetic the treatment required. He commences with 6 to 8 mg. of sublimate and pushes it rapidly to 14, 16 or 18 mg., repeating the injections nearly every day, and supplementing them with the usual frictions, intramuscular injections of sublimate, calomel or pills of protoiodid, with brief intervals of suspension of all specific treatment or change to potassium iodid. The strictest hygiene of the mouth and frequent use of potassium chlorate, sodium borate and alum was always successful in curing the slight tendency to salivation observed in a few instances after the first injections. General weakness was occasionally noticed during the course of treatment, and this he combated by hygienic measures and administration of a tonic containing iron, arsenic, phosphorus, manganese and strychnin. Out of the total of 44 30 were completely cured of their syphilis, not a trace of secondary manifestations having been observed since. In 6 others he was equally successful, but was not able to follow the cases as long as he wished and consequently does not include them in his 30 cases of complete cure. The drawbacks of the method are the occasional painful lumps at the point of the injection, or slight suffusion of blood, phlebitis, subcutaneous edema or erythem. None of these local inconveniences were serious, and they were all due to imperfect technic, not to the method, and are easily avoided. Another drawback is the metallic taste in the mouth and the salivation. Both were rare and not severe. No stomatitis was observed in any instance. Other drawbacks are a slight degree of general muscular weakness, slight headache, slight fever, very rarely, a general malaise and stomach troubles. None of these inconveniences were serious enough to require suspension of the treatment, and all soon vanished under appropriate accessory measures. No thrombosis, embolism or coagulation was noticed after any of the intravenous injections. His experience justifies the conclusions that intravenous injection of sublimate is harmless, even with the dose of 2 cg. Commenced promptly in the primary period and continued as energetically as possible, followed by a course of the ordinary mercurial treatment during several months, it will positively abort syphilis in a proportion of 80 per cent. of all cases. He describes the details of his 44 cases. Some received 15 injections, others 20, 23 in 37 days, or 32 in 43 days. The total of sublimate injected ranged from a few cg. to 17; 28.1 and 31.6 cg. The cases in which this intensive treatment failed illustrate the time limits for its effectiveness. In a young man of 19 the injections were commenced 31 days after infection. Twenty-five injections were made in 29 days, and then 8 more after a brief interval. The total injected was 210 mg. with an average of 6 mg. at each injection. Larger doses induced headache. No secondary manifestations have developed, although several years have elapsed, and no supplementary mercurial treatment was attempted in this case. The syphiloma usually vanished with the sixth to eighth injection.

27. **The Blood in Purpura.**—Lenoble asserts that purpura is a myeloid affection, distinguished by the absence of retraction of the clot and of transudation of serum, by the constant myeloid reaction, sometimes intense, characterized by the profound changes in the hematoblasts, which are diminished in number but increased in size, with a more or less complete loss of specific spontaneous alterability, and of their tendency to cling together. The majority are precipitated. Thus is explained the absence of retraction of the clot, the special anemia and the profuse hemorrhages characteristic of this affection, which he calls the disease of the bone marrow *par excellence*. It resembles myelogenic leukemia and also pernicious anemia,

but differs from them as all the blood-forming organs are involved in them. Every petechial eruption, with or without hemorrhagic manifestations, is true purpura when the formula of the blood is of the above character. Every purpuric exanthem, with or without hemorrhagic manifestations, but with normally constituted blood, is an affection extraneous to the blood-forming organs. The attenuated myelocytic reaction is not alone specific, but becomes so when accompanied by a normoblastic reaction, however slight.

29. **Technic of Phototherapy.**—Leredde extols the exalted scientific conscientiousness which distinguishes all of Finsen's writings. He has recently visited Copenhagen and announces that Finsen has now thoroughly established that the intensity of the superficial reactions is no criterion of the deep reactions. Comparative tests of the penetrating power of the various lamps employed in phototherapy, show that all are far inferior to Finsen's apparatus, although theoretically improvements on it. The tests are made with a plate of photographic paper on which are placed the superposed ears of rabbits. Through two rabbit ears the Finsen apparatus affects the paper in 5 seconds, the Lortet and Genoud apparatus in 20, while the Bang lamp requires 5 minutes to produce the same effect. Through 3 rabbit ears the Finsen requires 20 seconds and the Lortet apparatus 4 minutes. Through 4 ears the Finsen requires 2 minutes, while the Lortet apparatus fails to affect the paper at any time. The consequences of these tests are extremely important. They show that phototherapy requires foci concentrating on a limited spot a large quantity of violet rays, that is, great luminous intensity. Finsen and Reyn have constructed a lamp for application of the light treatment to a single patient. The lamp regulates itself automatically; has a force of 20 amperes and 55 volts and requires a direct and continuous 100-volt current.

30. **Cytodiagnostic of Syphilis.**—Ravaut has found that the cerebrospinal fluid is liable to contain cellular elements, reflecting the intensity of the reactions in the meninges which have been noted in syphilitic affections of the nervous system. In many cases the cerebrospinal fluid disclosed the presence of the cellular elements long before any clinical manifestations were apparent. This allowed energetic mercurial treatment to be instituted, which warded off the impending serious complication. They are more numerous in the fluid when the lesion is in its early stage, and become attenuated as they become cicatrized.

32. **Intensive Mercurial Treatment.**—Leredde proclaims that we have no reason for continuing to cling to mercurial frictions in the treatment of syphilis. Before the introduction of insoluble injections they were the best means known and were generally more active than mercury by the gastric route. But now they should be abandoned without regret. The only means of knowing the exact amount of mercury we are introducing into the system is by injecting it. Injections are to-day the only mode of mercurial treatment which allows us to realize what may be called an intensive mercurial treatment. There need be no fear of stomatitis if the mouth has been put in perfect order. The dose for an adult man, free from any special susceptibility to mercury or renal trouble, may be .02 to .035 of mercury daily, in the form of the benzoate or biniodid. By careful supervision of temperature, weight, digestive tract and the urine, it is soon possible to determine the largest dose that can be taken without disturbance. The dose of .02 was always well tolerated by his adult patients, and he accepts this as the minimum amount for intensive treatment, but it must be individualized for each patient.

35. **Non-Existence of Inherited Immunity to Syphilis.**—In his extensive experience in Asia Minor, where syphilis is almost endemic, Von Düring has become more and more firmly convinced that the descendants of syphilitics are entirely lacking in any special resistance to fresh infection, but acquire it like other persons free from any hereditary taint. He mentions as an instance that in a certain secluded village 110 of the 160 inhabitants had syphilis, and 30 children, including 25 between 7 and 12 years old, bore evidences of recently-acquired syphilis. The disease was introduced into this region early in the last century, and as 30 to 200 on an average in each village are syphilitic, the third and fourth generation would certainly exhibit some degree of immunity if such a thing as an inherited immunity were possible. But the children in these families acquire syphilis the same as the children in other families free from syphilitic antecedents.

38-40. **Serum Treatment of Scarlet Fever.**—These articles are claims for priority in certain discoveries in regard to serum treatment of scarlet fever, Baginsky maintaining Aronson's claims against Moser.

41. **Action of Oxygen on Osmotic Tension.**—Loewy found in his tests that the freezing-point of the blood has a tendency to rise on inhalation of oxygen. This he establishes is not due directly to the oxygen, but is merely the result of the deeper breathing induced by the inhalations. The better ventilation of the lungs, therefore, is the main factor in the benefit derived from inhalation of oxygen, in his opinion.

42. **Entering Points for Tuberculosis in the Throat.**—Ito examined under the microscope the tonsils, uvula, etc., of 104 cadavers. Not a single case of certain primary tuberculosis was found among them, and secondary lesions were noted in only 6.

48. **Alcohol in Therapeutics.**—Binz asserts that the growing tendency to refrain from the use of alcohol in therapeutics costs the life of many a patient who might have been saved by the judicious administration of some good alcoholicum in threatening collapse or inanition. Clinical experience harmonizes in every point with the results of the later scientific researches on the subject.

50. **Otitic Symptoms in Case of Injuries of Head.**—Stenger's experience has demonstrated that if functional tests of the hearing result positively, they afford reliable evidence as to the severity of the traumatic injury and exclude simulation. A peripheral trauma may affect the cerebrum, but the symptoms differ from those observed in case of concussion of the brain with simultaneous injury of the organ of hearing.

57. **Local Application of Heat.**—Davidsohn reiterates his former announcements as to the extreme practical value of his method of applying constant heat. It is free from the disadvantages of other methods; the appliance is light, convenient and answers every requirement. The principle of the appliance is merely a coil of narrow, rather stiff rubber tubing through which a constant stream of hot water is passed from a receptacle over a spirit lamp. When the tubes are once full the faucet is turned so that only a drop flows out at a time, thus economizing the hot water. One convenient form is a square cloth on which the rubber tubing winds back and forth two or three times, one end of the tube extending to the receptacle and the other reaching down to a vessel under the bed. When heat is to be applied to the entire body the tubing winds back and forth a number of times in the outline of a human body. The two tubes entering from the boiler separate into two branches each, thus equalizing the heat for the four members and trunk.

58. **Blood Changes in Syphilis.**—In this article Justus reviews the various communications that have been published on the "Justus blood test" and states that his own experience now includes 22 cases. In his latest series of 10 cases in which the syphilis was dubious, the characteristic decline in the hemoglobin after administration of mercury, which is the essence of his test, was confirmed by the rapid recovery under specific treatment. In all the publications on the subject he knows of only two experimenters, Brown and Dale, who obtained negative results in undoubted syphilis. But he points out that these writers administered only 20 grains of mercury, which is too small a dose to induce the characteristic reaction. It subsides the second to fourth day after adequate mercurial treatment has been instituted.

59. **The Blood in Late Syphilis.**—These writers establish that both hemoglobin and the proportion of iron are materially diminished in the later phases of syphilis and also in the maligna precox form. The findings of both ferrometer and hemamometer harmonize. The red corpuscles range within normal limits.

60. **Sclerosis of Tracts of White Matter.**—Kattwinkel describes the clinical history and autopsy findings in 8 cases of acquired sclerosis of these various tracts combined. In most cases there was a paralytic enfeeblement of the lower and in one instance also of the upper limbs, besides the ataxia. It amounted to complete paraplegia in 2. Nothing abnormal was noted in the brain except possibly a slight tendency to thickening of the meninges and edema, with a scarcely appreciable atrophy of the cortex. Externally the cord appeared to be intact, but transverse sections revealed extensive degeneration of both the longitudinal and the endogenic fibers. In the upper portion of the cord the degeneration involved the posterior columns, the lateral pyramidal fasciculus, and the cerebellar and Gowers' columns with small scattered foci in the anterior columns. The degeneration could be traced with the Weigert to the medulla oblongata and with the Marchi into the pons. The lesions were most pronounced in the dorsal region, and diminished below until the pyramidal tracts were the only ones affected in the lumbar region. Close study of the findings under the microscope clearly demonstrates that the lesions originated in some affection of the local lymphatic system. In every case signs of a morbid process in the lymphatics were prominent. The lymph-spaces were much dilated, the central canal enlarged and choked with cellular elements. Thickening of the adventitia of the vessels was frequently observed, with obliteration of the lymph-clefts in the adventitia and occlusion of the epispinal lymph-spaces from the almost invariable thickening of the pia and its adhesion to the spinal cord. The lymph stream had evidently been checked and stagnation ensued.

61. **Streptothrix Pyemia.**—In the case described peculiar fungous filamentous threads were disclosed by the Gram in the pus of abscesses in all the organs examined as well as in the single vessels. No other micro-organisms were discovered. The patient was a previously healthy young man. Four months before entering the hospital he complained of loss of vitality and appetite, with fever. During the last week there had been pain in the right side, with cough and expectoration. He died a month later and metastatic abscesses were found in all the vital organs, containing the fungous growths above mentioned.

66. **Specific Serum for Human Placenta.**—Liepmann's success in producing a biologic serum by injection of scraps of human placentæ, was proclaimed in No. 51 of the *Wochenschrift*, last December. He now announces that it is possible by this means to determine the presence of particles of the placenta in the blood of pregnant women as well as in the serum from the umbilical cord of the fetus. The reaction is the same as in the biologic blood test. No reaction was observed in blood from male subjects or from non-pregnant women.

71. **Etiology of Dysentery.**—Rosenthal's communication describes an epidemic of 85 cases of dysentery at Moscow induced by the Shiga-Kruse dysentery bacillus. In one case the bacilli had caused general septicemia. Pure cultures were derived from the spleen and mesenteric glands and in the excreta these bacilli were in the overwhelming majority. The bacilli remained alive in the stools for eight days at room temperature and for eleven at the freezing point. On fruits and vegetables they also remained alive for seven or eight days, and on water melon for eleven.

73. **Diabetes Mellitus and Gynecologic Operations.**—Füth has witnessed three deaths in diabetic coma, the seventh, eighth and fifth day in 3 cases of operation for cancer of the uterus in diabetics. Becker has also warned of the dangers of narcosis in diabetics and collected 9 fatal cases. Füth concludes that surgical intervention on diabetics must be surrounded with exceptional precautions. In the first place, the sugar must be banished from the urine before attempting to operate. Strict diabetic diet may be enforced, with prophylactic administration of sodium bicarbonate (Naunyn) or sodium citrate (Rumpf). The patient must also be brought into a tranquil state of mind. Purges and enemata must be avoided for fear of inducing weakness, and the supply of fluids must not be allowed to fall below the average. One enema should be

given the night before the operation, and the latter should be done in the early forenoon in the period of physiologic hunger and thirst. The entire operation should be done without general narcosis. A laparotomy should be commenced with local anesthesia and continued without narcosis as long as possible, as suggested by Veit. Spinal cocainization may find its most useful application in these cases. As soon as the intervention is completed, fluids should be supplied as abundantly as possible by the rectum. As soon as any way practicable the patient should be given easily-digested solid food, with prophylactic administration of sodium citrate. When the recovery is progressing normally the physical exercise, so indispensable for diabetics, should be substituted by massage. In 6 or 47 per cent. of the 14 gynecologic operations on record, the patients died in diabetic coma after a period of well-being. Hirschberg also lost a patient from the same cause after a brief operation on a cataract under cocain. In his second similar case the patient finally recovered. Füth's article is an elaborate review of all experiences in Germany to date.

75. **Collargol in Septic Processes.**—Jaenicke remarks that it requires considerable courage to inject into the veins of an emaciated, fever-ridden, extremely sick woman, the inky, turbid fluid of a 1 per cent. sterilized solution of Credé's collargol. But in the case of septic parametritis which he describes the effect was most remarkable. In thirty-six hours the patient was entirely free from fever, and would undoubtedly have had no further temperature had it not been for the development of venous thrombosis in the left leg, which threatened trouble, but soon vanished harmlessly. An exudate producing a tumor as large as the head of a child subsided spontaneously in four and one-half days. The dose injected in the vein at the elbow was only 8 c.c., but the arm was painful and helpless for a few days.

77. **Origin of Terms Icterus, Jaundice, Etc.**—Ebstein quotes from ancient and medieval writings to show that it has been a custom from time immemorial to treat the "yellows," icterus, jaundice, etc., with yellow objects. The very word icterus denotes a yellow bird, which was tied to the bedside of the patient. This practice is mentioned in the Atharva Veda. The German word for bile, Galle, is derived from the Latin giallus, yellow. Jaundice originated in the French term for yellow, Jaune. Yellow roots, vegetables, saffron, etc., have been used in treatment and especially yellow birds.

78. **Prevention of Tuberculous Infection at Health Resorts.**—Büdingen emphasizes the danger of promiscuous intercourse and change of lodgings between consumptives and persons suffering from other affections of the upper air passages. He proposes several measures which he thinks would counteract this evil and might easily be enforced by the municipality at health resorts. In the first place, each householder should be visited and required to state whether he wishes to take tuberculous guests under his roof. If he replies in the affirmative then the house should be inspected by the authorities and a certificate delivered as to its suitability for persons suffering from tuberculosis. If passed on favorably, then the householder is entitled to receive tuberculous guests, but must reject those who are non-tuberculous. If a tuberculous person stops in a non-certified house, the attending physician must advise removal and notify the authorities in case of refusal, and the latter must attend to moving the patient within two days. Neglect to notify or to compel the removal of a tuberculous patient from a non-certified house or of a non-tuberculous patient from a house given up to tuberculous guests, should entail a fine on the physician or suspension of his practice. This latter point is important, as it relieves the physician of the responsibility of resisting the importunity of persons who may dislike some of the measures. If these precautions were enforced in health resorts there would be no danger of a non-tuberculous person occupying a room just vacated by a consumptive. The consumptives would be housed in rooms suitable for them, and non-resident physicians would feel much safer in sending their patients to a place where such regulations were enforced and could direct them to certain hotels, sanatoria or private houses. Guests at such places who cough or are otherwise suspicious of tuberculosis should be noticed by the physicians and urged to submit to an examination. In Baden there is already a decree compelling the attending physician to notify the authorities whenever a person in advanced tuberculosis changes his lodgings or is deemed a menace to his surroundings from any cause. Disinfection of rooms vacated by consumptives is also obligatory.

79. **Treatment of Toxic and Infectious Psychoses with Saline Infusion.**—Donath uses what he calls an artificial blood-salts solution, absolutely isotonic for the blood, and reports astonishingly favorable results from its infusion. One of his patients with progressive paralysis who had long been obliged to give up his business as a traveling man, was enabled to return to it, completely restored. In 4 others the improvement was also marked and permanent, but one of the 6 cases was not improved. He found it very effective also in a case each of cerebral syphilis, tetany and melancholia. The earlier the stage in which it is applied the better the results. Gaspero has recently reported the great benefits derived from saline infusion in various psychoses at Anton's clinic, in catatonia, amentia, stupor, delirium acutum, melancholia agitata, etc. The patients increased in weight and the mental disturbances were very favorably influenced. Donath's formula corresponds to the total ash of the blood, omitting the calcium and magnesium, which would be precipitated in such a solution. The blood corpuscles are not affected, even when left in it for twenty-four hours. It contains in 1000 gm. of distilled water, .25 gm. of potassium sulphate; 1 gm. of potassium chlorid; 6.75 gm. of sodium chlorid; .4 gm. of potassium carbonate, and 3.1 gm. of cryst. sodium phosph. The jar in which the mixture is kept is of glass and has three holes in the rubber stopper. In one of these holes a thermometer fits which reaches close to the bottom of the jar. In another hole fits a glass tube which also reaches close to the bottom of the jar and is bent at an acute angle, where it projects above the stopper. The rubber tube conveying the fluid is attached to its end. A short glass tube fits into the third hole. It reaches only a short distance above and below the stopper. The upper end is plugged with cotton, tied on with a piece of gauze and a rubber band. This supplies filtered air to the jar. The fluid is injected through a Dieulafoy aspirator, 500 to 1000 c.c. at a time, every three or four days. The jar is sterilized by being boiled in another vessel.

82. **Treatment of Acute Infectious Diseases.**—In Wernitz's experience at Odessa he has derived inestimable benefit from copious rinsing out of the body with a saline solution. He does not introduce it subcutaneously on account of the inconveniences of this route, but merely keeps up an almost continual irrigation of the lower intestines according to the method suggested by Hegar. The effect is even more pronounced than that of subcutaneous injections. Diuresis is remarkably promoted, while the patient does not experience thirst. The fluid is supplied in abundance, and the system can absorb as much or as little as it requires. In saline infusion the system has to take the amount that is introduced, irrespective of its actual needs. By the intestinal route the heart is never over-burdened. He uses a tepid 1 per cent. salt solution, with a moderately long rectal tube. The receptacle for the water is placed beside the bed and raised sufficiently to allow the water to flow in very gently. If there is a desire for defecation the receptacle is lowered and the diluted alvine discharge flows

into it. The receptacle is then rinsed and filled with fresh saline fluid and the irrigation resumed. The injection must not disturb the patient in any way. The urine frequently amounts to 5 or 6 quarts in the twenty-four hours. He allows a quart of the saline solution to each injection, and prolongs the time to about an hour, interrupting the flow occasionally to avoid inducing peristalsis or desires. The injection is repeated every hour or two. If a peristaltic movement does occur it is not felt as a desire after the first. The fluid in the receptacle merely rises a little, showing that the pressure in the intestine is a little augmented. He describes some typical examples to illustrate the great benefit derived from the procedure, which he recommends as a notable improvement over infusion or any other method of supplying the necessary fluid to the organism in acute infectious diseases. He usually makes about ten injections in all.

88. **Inhalation and Disinfecting Apparatus.**—Saenger's apparatus is described and illustrated. Its chief advantage is that the spray is directed in a very powerful jet, which much facilitates the action of the disinfectant.

92. **Bloodless Epiphyseolysis for Genu Valgum.**—Reiner is assistant at Lorenz's Universitäts-Ambulatorium for orthopedic surgery at Vienna. He reviews the history and experiences of epiphyseolysis in the treatment of genu valgum adolescentium, and proclaims that it is by far the simplest, easiest and most rational method of overcoming this deformity. The epiphysis heals smoothly almost without exception, and without inflicting any permanent injury. Quite recently Codivilla published a series of 1,031 cases thus treated at Milan and Bologna, and the only complication observed in any case was paralysis of the peroneus nerve, which occurred in 34, but proved briefly transient in 32. It was permanent in only 2 instances, and was probably due to defective technic in applying the cast. The epiphysis had been detached smoothly as the radiograms showed, with or without circumscribed fracture of the diaphysis. The functions of the epiphysis were not disturbed in any way. Reiner restricts the intervention to subjects over 8 and under 17. Within these age limits he has been invariably successful. The apparatus which he uses screws like a vise to the operating table and holds the limb firm, while he works the leg as a lever. The resistance to be overcome is least at the epiphysis, and especially at the knee. The operation is done in profound narcosis. The construction of the apparatus can be seen from the cuts. An important point is the slope of 20 degrees from the horizontal, and also the groove large enough to admit the finger of the operator. The epiphysis is found 1 to 1.5 cm. above the greatest prominence of the inner condyle, and it is placed exactly on the groove. The forefinger of the left hand is kept in the groove during the entire intervention, with the middle finger on the median surface of the knee. The right hand holds the other side of the knee joint. The operator stands with the leg on his right. The force applied must be rapid and regularly increasing, not jerky. It is unnecessary and unwise to attempt to complete the operation at the first attempt. After exerting the regular force with hands, forearms and elbows, the operator should give up and start afresh, but never removing his hands or the fingers from their places. The slightest displacement of the thigh on the block should be corrected at once. The maneuver

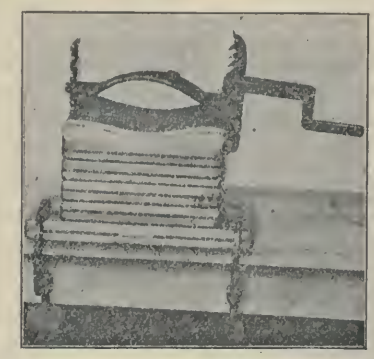

Figure 1.

is repeated as often as necessary until the desired result is attained. In many cases it is accomplished at the first attempt. It is indispensable that the condition of the epiphysis should be determined by radiography in persons approaching the age limit. Some of his patients were able to flex the knee without pain as early as three to five days after the intervention.

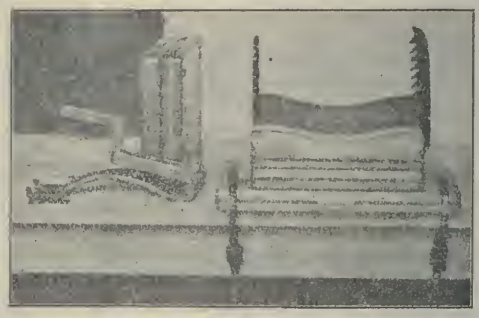

Figure 2.

The subcutaneous hematoma and the pains are always trivial. The cast applied is worn for five to seven weeks. Epiphyseolysis attacks the deformity at its culminating point and reduces the functional shortening to the least possible minimum. The after-treatment is shorter than after other interventions for correction of this deformity. It does not interfere with

Figure 3.

the later development of the extremity. He gives radiographs of several typical cases, and describes the anatomic findings in his experiments on the cadaver.

95. **Treatment of Lax Paralysis of the Legs.**—Möller recommends a walking cast, such as Krause applies in cases of fracture of the leg. The limb is placed in it in over-

correction. The child can begin to walk in it after two days. The cast is taken off in four to six weeks, the position of the leg corrected, and a cast applied again, while a supporting apparatus is made. It answers the purpose merely of retention and substitution. As the child has already been walking in its cast, the supporting Hessing apparatus causes no disturbance. If the physician wishes to dispense with an apparatus by transplantation of tendons, the conditions are the most favorable possible at this stage. The muscles have been strengthened by use in the cast, and even arthrodesis is more readily done. Four children, treated on these principles, were able to walk with a chair or cane two to five days after application of the cast, while before that the extensive paralysis of both legs had rendered any attempt to walk or stand impossible. Two other children with almost total paralysis, and two others with paralytic clubfoot were treated in the same way, and the results have been surprisingly satisfactory.

98. **Anatomic Conditions After Bloodless Reduction of Congenital Dislocation of Hip.**—Müller gives illustrations of lengthwise sections of two hip joints from children whom he had treated by bloodless reduction a few months and two years before. One had died from meningitis and one from pneumonia. The conditions in the hip treated two years before were almost ideally physiologic. The head of the femur rested in a cavity resembling the normal acetabulum, and enclosing more than two-fifths of a circle. The roof was broad and thick, but, as it consisted almost entirely of cartilage, in radioscopic examinations the conditions did not appear as perfect as they were in reality. The two cases emphasize the importance of the conditions in the capsule in regard to the ultimate outcome. The large recess in the capsule, in which the head formerly rested, is empty after reposition, but, on account of its elasticity, the capsule retracts and, by the pressure of the surrounding parts, folds down on the head of the femur, clinging closely to the latter and holding it in its new place. The capsule continues to shrink and the folds gradually become smoothed out until, in time, the capsule stretches smoothly and normally from its attachment to the acetabulum to its insertion in the neck. This must occur very early, as in one of the joints described, examined only six and one-half weeks after reposition, the capsule was stretched so taut that even after removal of the bandages the head remained in the acetabulum, at least while the child lay in bed and was carried. If weight had been borne on the limb and adduction had occurred, the capsule would probably not have been strong enough to stand the pressure. This can be counted on after three or four months, which, therefore, Müller accepts as the minimum interval before removing the cast. The capsule now holds the head in place and, by exercising its functions, the joint gradually builds up the bony and cartilaginous formations, which restore conditions in the joint to the nearly normal state seen in the first of the specimens he illustrates. These formations certainly have some beginning while the limb is in the cast, especially at the cartilaginous rim of the acetabulum on its anterior and upper margin. The constant pressure of the capsule transforms, even at this early date, the shape of the cavity from a plate more to that of a cup. The strong tension of the anterior wall of the capsule obtained by the vigorous abduction has a twofold purpose: it tilts the edge of the acetabulum, and also presses the head into its cavity, neither of which could be accomplished by the cast alone. Atony of the capsule from long disuse excludes this important factor in the cure and, hence, it is advisable to wait patiently quite a long time if treatment fails, before renewing the attempt. His experience includes 40 cases of unilateral luxation, and 70 per cent. have been completely cured. He attributes his success to his practice of applying the cast down to the ankle in pronounced abduction and outward rotation, with the knee stretched. This best insures the retention of the head in the acetabulum. In several cases the cavity was so shallow that success seemed absolutely impossible, but treatment on these lines has resulted in permanent correction of the luxation. The results in bilateral luxation have not been so favorable. Only 5 of the children have been permanently cured. He ascribes the failures to the fact that at first he included subjects really too old for this method of treatment, and also to his former practice of treating both joints at one sitting, by which he lost the beneficial effect of functional use of the joint. No time is gained in the end, and many advantages are thrown away by attempting to treat both hips at once. Massage or other after-treatment is not necessary for young children. He concludes with the remark that many of the failures in the unsuccessful cases were due to the lack of intelligence on the part of the parents, or else the cases date from the earliest days of the method. He thinks he can safely say that in by far the largest majority of cases it is possible to obtain complete cure by bloodless reposition.

100. **Treatment of Subjective Troubles of the Middle and Front Foot.**—Hasebroek refers to the pains and other disturbances in the articulation between the astragalus and calcaneus and the navicular and cuboid bones, and between the navicular and the three cuneiform bones. Also in the articulation between the cuboid and cuneiform bones and the metatarsal bones. He considers the pains in these joints, with the bones intact, an affection *sui generis*. The disturbances in the first articulation resemble the pains of flat-foot, but they are undoubtedly due to some slight and forgotten traumatic injury, to some local rheumatic or gouty process, or to an actual neurosis of the joint. Many cases of supposed flat-foot unmistakably belong in this category, especially those that do better without the flat-foot support. Treatment should be massage and gymnastics of the joint, with treatment of the underlying cause, if possible. A support for the joint may also be necessary, a celluloid insole. He recommends his patients to buy their shoes ready-made at a large establishment, instead of having them made to order, subject to the whims of some conceited shoemaker. Mild rheumatic affections recover most rapidly; the gouty or senile cases are more obstinate, and the neuroses are sometimes rebellious. In prophylaxis, a supporting insole will be found effective in preventing the tendency of the foot to turn over. Children whose ankles turn and who, thus, are unable to skate, will sometimes be completely cured by the supporting insole. This turning over of the foot is liable to cause injury of the joint and the wearing of the insoles may prevent the above disturbances later. The disturbances in the other articulation, the "Lisfranc joint," include stiffness, with a tendency to plantar flexion and turning in of the front portion of the foot. The pains are localized more between the great and second toes and are accompanied by callous growths under the ball of the great, second and third toes. Hasebroek thinks that the anatomic structure of the forefoot in relation to the middle foot and arch is responsible for the development of corns and callosities more than the footgear. Treatment of disturbances in this point should include massage and gymnastics, supplemented by raising the forefoot by an appropriate insole. It should rise gently and supply a slight flat expanse for the front part of the foot. The relief is immediate. The footgear should be long enough and allow plenty of room. These insoles should be used whenever a tendency to callous growths at these points is observed. They may avert trouble later.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Diseases of the Skin: Their Description, Pathology, Diagnosis and Treatment, with Special Reference to the Skin Eruptions of Children, and an Analysis of 15,000 Cases of Skin Disease. By H. Radcliffe-Crocker, M.D. (Lond.), F.R.C.P., Physician for Diseases of the Skin in University College Hospital. Third Edition, Revised and Enlarged. With Four Plates and 112 Illustrations. Cloth. Pp. 1466. Price, $5.00. Philadelphia: P. Blakiston's Son & Co. 1903.

Harrington's Hygiene. A Manual of Practical Hygiene for Students, Physicians and Health Officers. By Charles Harrington, M.D., Assistant Professor of Hygiene in the Medical School of Harvard University. Second Edition. Revised and Enlarged. With

113 Engravings and 12 Full-page Plates in Colors and Monochrome. Cloth. Pp. 755. Price, $4.25 net. Philadelphia and New York: Lea Brothers & Co.

THE DIAGNOSIS AND MODERN TREATMENT OF PULMONARY CONSUMPTION, with Special Reference to the Early Recognition and the Permanent Arrest of the Disease. By Arthur Latham, M.A., M.D. Oxon., M.A., Cantab., Author of the Prize Essay on the Erection of His Majesty's Sanatorium. Cloth. Pp. 215. Price, $1.50 net. New York: Wm. Wood & Co. 1903.

DISEASES OF WOMEN. A Clinical Guide to Their Diagnosis and Treatment. By George Ernest Herman, M.B. Lond., F.R.C.P., Obstetric Physician to and Lecturer on Midwifery at the London Hospital. With Upwards of 250 Illustrations. Revised Edition. Cloth. Pp. 884. Price, $5.00 net. New York: Wm. Wood & Co. 1903.

INDEX-CATALOGUE OF MEDICAL AND VETERINARY ZOOLOGY. Part 2. (Authors: B to Buxton.) By Ch. Wardell Stiles, Ph.D., Consulting Zoologist of Bureau of Animal Industry, and Albert Hassall, M.R.C.V.S., Acting Assistant Zoologist of Bureau of Animal Industry. Paper. Pp. 198. Washington: Government Printing Office. 1903.

A TEXT-BOOK OF PRACTICAL MEDICINE. For the Use of Students and Practitioners. By William Gilman Thompson, M.D., Professor of Medicine in Cornell University Medical College. Second Edition, Thoroughly Revised. With 62 Illustrations. Cloth. Pp. 1104. Price, $5.00. Philadelphia and New York: Lea Brothers & Co.

THE INTERNAL SECRETIONS AND THE PRINCIPLES OF MEDICINE. By Charles E. de M. Sajous, M.D., Fellow of the College of Physicians of Philadelphia. Volume I. With 42 Illustrations. Cloth. Pp. 800. Price, $6.00. Philadelphia: F. A. Davis Co. 1903.

QUARTERLY PUBLICATIONS OF THE AMERICAN STATISTICAL ASSOCIATION. I. The Vital Statistics of the Census of 1900. By Frederick L. Hoffman. Paper. Pp. 202. Boston: J. P. Shults. 1902.

REPORT OF MINISTER OF AGRICULTURE for the Dominion of Canada for the Year Ended Oct. 31, 1902. Printed by Order of Parliament. Paper. Pp. 284. Ottawa: S. E. Dawson. 1903.

PUBLICATIONS OF THE MISSISSIPPI HISTORICAL SOCIETY. Edited by Franklin L. Riley, Secretary. Vol. VI. Cloth. Pp. 567. Oxford, Miss.: Printed for the Society. 1902.

REPORT OF THE COMMISSIONER OF EDUCATION for the Year 1900-1901. Volume I. Cloth. Pp. 1216. Washington: Government Printing Office. 1902.

The Public Service.

Army Changes.

Movements of officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., from Feb. 7 to 20, 1903:

Brown, Justus M., colonel and assistant surgeon-general, U. S. A., at his own request, under the provisions of the Act of Congress approved June 30, 1882, has been retired by the President from active service, Feb. 13, 1903, he having served more than forty years.

McCallum, Francis M., contract surgeon, U. S. A., in addition to his present duties at Indianapolis Arsenal, is assigned to duty as examiner of recruits at Indianapolis, and will report in person accordingly to Major James E. Macklin, Eleventh Infantry, recruiting officer at that place.

Agramonte, Aristides, contract surgeon, now at Havana, Cuba, will report in person to the commanding officer, Cabana Barracks, for temporary duty and by letter to the commanding general, Department of the East.

De Shon, George D., captain and asst.-surgeon, having reported his arrival at San Francisco, in compliance with orders heretofore issued, will proceed to Boston and assume the duties of attending surgeon and examiner of recruits in that city. Captain De Shon will report by letter to the commanding general, Department of the East.

O'Neill, Joseph A., contract surgeon, U. S. A., is ordered to report in person not later than Feb. 16, 1903, to the commanding officer First Battalion, Fourteenth Infantry, at Fort Brady, Mich., for duty to accompany that battalion to the Philippine Islands, and on arrival at Manila to report in person to the commanding general, Division of the Philippines, for assignment to duty.

Winn, Robert N., first lieut. and asst.-surgeon, U. S. A., is relieved from further duty at Fort Riley, Kan., and will proceed to Fort Grant, Ariz., and report in person to the commanding officer of the latter post for duty and by letter to the commanding general, Department of the Colorado.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending Feb. 28, 1903:

Surgeon J. G. Field, detached from duty with recruiting party, and ordered to the *Bennington*.

A. A. Surgeon G. G. Hart, ordered to duty with recruiting party.

Surgeon J. W. Ross, appointed medical director from Feb. 5, 1903.

A. A. Surgeon J. C. DeVries, appointed acting asst.-surgeon, Feb. 16, 1903.

Surgeon E. H. Marsteller, ordered to the *Panther* via the *Raleigh*.

Medical Director A. F. Price, detached from the Naval Hospital, Washington, D. C., and ordered to the navy yard, New York.

Surgeon G. B. Wilson, detached from the *Panther* and ordered to the Naval Hospital, Chelsea, Mass.

Surgeon C. F. Stokes, detached from the *Oregon* and ordered home to wait orders.

Asst.-Surgeon B. L. Wright, detached from treatment at the Army General Hospital, Fort Bayard, N. M., and ordered to the Naval Hospital, Pensacola, Fla., for treatment.

A. A. Surgeon L. H. Schwerin, ordered to duty with recruiting party No. 4.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Feb. 26, 1903:

Asst.-Surgeon J. W. Kerr, to report at Bureau for special temporary duty.

Asst.-Surgeon B. S. Warren, granted extension of leave of absence, on account of sickness, for thirty days from March 1.

A. A. Surgeon M. H. Ross, relieved from duty at Cairo, Ill., and directed to proceed to Los Angeles, Cal., and report to medical officer in command for duty.

A. A. Surgeon F. F. Sams, granted extension of leave of absence, on account of sickness, for thirty days from February 17.

Pharmacist S. W. Richardson, granted leave of absence for seven days from Feb. 21, 1903, under provisions of Paragraph 210 of the regulations.

Pharmacist E. J. Thurston, to report to chairman of board for physical examination to determine fitness for promotion to the grade of pharmacist of the first class.

Pharmacist G. A. Morris, granted extension of leave of absence for seven days from February 18.

BOARD CONVENED.

Board convened at the Bureau, Washington, D. C., Feb. 25, 1903, for the physical examination of Pharmacist E. J. Thurston, of the second class, to determine his fitness for promotion to the grade of pharmacist of the first class. Detail for the board: Assistant Surgeon-General W. J. Pettus, chairman; Assistant Surgeon-General H. D. Geddings, recorder.

REINSTATEMENT.

E. J. Thurston, reinstated and appointed pharmacist of the second class.

CASUALTY.

A. A. Surgeon C. F. Ulrich, died Feb. 17, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Feb. 28, 1903:

SMALLPOX—UNITED STATES.

California: Los Angeles, Feb. 7-14, 3 cases; Sacramento, Feb. 7-14, 2 cases; San Francisco, Feb. 8-15, 2 cases.
Florida: Jacksonville, Feb. 14-21, 3 cases.
Georgia: Atlanta, Dec. 31-Feb. 18, 64 cases, 4 deaths.
Indiana: Elwood, Feb. 15-22, 6 cases; Evansville, Feb. 14-21, 6 cases; South Bend, Feb. 14-21, 2 cases.
Iowa: Des Moines, Jan. 1-31, 10 cases.
Kansas: Wichita, Feb. 7-14, 1 case.
Kentucky: Lexington, Feb. 14-21, 3 cases.
Maine: Biddeford, Feb. 14-21, 4 cases.
Maryland: Baltimore, Feb. 14-21, 1 case.
Massachusetts: Boston, Feb. 14-21, 10 cases; New Bedford, Feb. 24, 1 case.
Michigan: Detroit, Feb. 14-21, 20 cases; Grand Rapids, Feb. 14-21, 14 cases; Marquette, Feb. 7-21, 10 cases; Menominee, Feb. 7-14, 1 case; Port Huron, Feb. 14-21, 8 cases.
Missouri: St. Louis, Feb. 8-22, 26 cases.
Nebraska: Omaha, Feb. 7-14, 3 cases.
New Hampshire: Manchester, Feb. 14-21, 2 cases.
New Jersey: Camden, Feb. 14-21, 9 cases.
New York: Feb. 14-21, Buffalo, 1 case; New York, 3 cases.
Ohio: Cincinnati, Feb. 13-20, 20 cases; Cleveland, Feb. 14-21, 6 cases, 2 deaths; Dayton, Feb. 14-21, 7 cases.
Pennsylvania: Erie, Feb. 14-21, 7 cases; Johnstown, Feb. 14-21, 1 case; McKeesport, Feb. 14-21, 2 cases; Philadelphia, Feb. 14-21, 25 cases, 6 deaths; Pittsburg, Feb. 7-14, 12 cases, 3 deaths; Reading, Feb. 16-23, 1 case.
South Carolina: Charleston, Feb. 14-21, 3 cases; Greenville, Feb. 7-14, 2 cases.
Tennessee: Feb. 14-21, Memphis, 2 cases; Nashville, 1 case.
Utah: Salt Lake City, Feb. 7-14, 20 cases.
Washington: Tacoma, Feb. 9-16, 1 case.
Wisconsin: Green Bay, Feb. 15-22, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Jan. 24-31, 5 cases.
Belgium: Jan. 24-31, Antwerp, 8 cases, 1 death; Brussels, 4 deaths.
Germany: Hamburg, Jan. 31-Feb. 7, 3 cases.
Great Britain: Birmingham, Jan. 24-Feb. 7, 14 cases, 1 death; Dublin, Jan. 31-Feb. 7, 2 cases; Leith, Jan. 24-31, 2 cases; Liverpool, to Jan. 31, 176 cases, 13 deaths; London, Jan. 31-Feb. 7, 4 cases; Manchester, Jan. 31-Feb. 7, 36 cases; Nottingham, Jan. 31-Feb. 7, 4 cases; Sheffield, Jan. 24-Feb. 7, 5 cases, 1 death; Sunderland, Jan. 17-24, 1 death.
India: Bombay, Jan. 20-27, 14 deaths; Calcutta, Jan. 17-24, 2 deaths.
Russia: Odessa, Jan. 11-18, 2 cases; St. Petersburg, Jan. 24-31, 88 cases, 20 deaths; Warsaw, Jan. 3-17, 7 deaths; Warsaw, Jan. 24-31, 2 deaths.
Spain: Corunna, Jan. 31-Feb. 7, 1 death.
Uruguay: Montevideo, Dec. 1, 1902-Jan. 7, 1903, 9 cases, 2 deaths.

YELLOW FEVER.

Mexico: Vera Cruz, Feb. 7-14, 4 cases.

PLAGUE—INSULAR.

Hawaii: Honolulu, Feb. 12, 1 death.

PLAGUE—FOREIGN.

India: Bombay, Jan. 20-27, 455 deaths; Calcutta, Jan. 17-24, 76 deaths; Karachi, Jan. 11-26, 54 cases, 41 deaths.
Mexico: Mazatlan, Jan. 17-24, 51 cases, 27 deaths.

CHOLERA—FOREIGN.

India: Bombay, Jan. 20-27, 1 death; Calcutta, Jan. 17-24, 48 deaths.

OBSERVATIONS ON THE MECHANICS OF DIGESTION.*

WALTER BRADFORD CANNON, M.D.

INSTRUCTOR IN PHYSIOLOGY, HARVARD MEDICAL SCHOOL.

BOSTON.

The results which are to be presented in outline in this paper have been obtained in researches carried on in 1897-98 and in 1901 in the Laboratory of Physiology of the Harvard Medical School, and they are part of an extensive investigation into the mechanical factors of digestion to be carried on during the next few years. The method thus far pursued has been that of mixing with the food subnitrate of bismuth, a harmless, almost inert, powder, opaque to the *x*-rays, and then with the fluorescent screen observing the changes in the shadows of the alimentary contents as they are worked on by the muscles of the digestive organs. The clearness with which masses of food can be seen is indicated in Figure 1, a radiograph of a cat. Observations have been made chiefly on cats, but many of these observations have been confirmed on dogs, rats and guinea-pigs, as well as on the human subject. The results of the work on the movement of food in the esophagus,[1] on the movements of the stomach[2] and on the movements of the intestines[3] have already appeared. In this paper I shall review briefly some of the results already published on the activities of the stomach and intestines and report certain new observations.

The mechanical factors in digestion perform three functions: the propulsion of the food through the alimentary canal, the mixing of the food with the digestive juices and the exposure of the digested food to the absorbing mucous membrane. These functions are performed in different ways in different parts of the alimentary tract. For the sake of clearness, the methods and results of the activities of the stomach will first be considered, and later those of the large and small intestines.

When the stomach is observed according to the method above mentioned, it is seen to consist of two physiologically distinct parts, divided about half way between the cardia and the beginning of the antrum (Fig. 2). To the left of this division lies the cardiac portion or fundus of the stomach; to the right is the pyloric portion. The distinction between these two portions arises from a difference in muscular activity. Over the food in the pyloric portion waves of constriction are repeatedly passing. These waves start at the beginning of this division of the stomach and pass as deepening contraction rings to the pylorus. In the cat six of these waves pass a given point in a minute, in the white rat, also, about six waves per minute, in the dog between four and five, and in the guinea-pig seven. The fundus is characterized by a total absence of peristalsis; as the food is pressed out of the pyloric portion, however, by the repeated constrictions, the muscles of the fundus slowly contract and squeeze the contents into the more active division. Since the stomach is an organ more devoted to digestion than to absorption, the mechanical processes of mixing the food with the digestive juices and of propelling the food into the intestines are here of first importance.

The efficiency of the gastric peristalsis as a means of mixing the food with the gastric secretions depends on the contraction of the pyloric sphincter. Careful observation reveals that the pylorus does not open for every wave of constriction which approaches it, but only at irregular intervals. So long as the sphincter holds tightly, each ring of constriction as it courses from the middle to the end of the stomach presses the food into a blind pouch; the food, unable to escape through the pyloric opening, has as its only outlet the opening in the advancing ring. Thus each peristaltic constriction in moving toward the pylorus has all the contents of the pyloric portion streaming back through the contracted ring. Beaumont, in his famous researches on Alexis St. Martin, declared that the gastric contents circulated first along the greater curvature from cardia to pylorus, then back along the lesser curvature. He gave, however, very meager evidence to support this statement. Brinton, for theoretical reasons, believed that the food must move forward along the sides of the stomach and backward through the middle. The value of the circulation of the food, as described by these men, lay in the supposition that the food was thus brought near to the secreting gastric wall and that the gastric secretion could thereby more readily exert its action. Observations made with the *x*-rays do not support these theories of mixing currents running throughout the stomach, but nevertheless they show that the pyloric portion is an admirable device for bringing all the food under the influence of the glandular secretions of that region.

Little paste pellets of bismuth subnitrate with starch enough to keep the form may be distinguished from the remainder of the stomach contents by the darker shadows which they cast. Several times I have been fortunate in seeing two of these pellets about a centimeter apart in the axis of the stomach. As a constriction wave ap-

1. Cannon and Moser: American Journal of Physiology, 1898, I, p. 435.
2. Cannon: Ibid., 1898, I, p. 359.
3. Cannon: Ibid., 1901, vi, p. 251.

proached them, both moved forward, but not so rapidly as the wave. When the constriction overtook the first ball, the ball moved backward through the constricted ring in the direction of least resistance. The wave then overtook the second ball and this also passed backward to join its fellow. At the approach of the next wave they were both pushed forward once more, only to be again forced backward, one at a time, through the narrow orifice. As the waves recurred in their persistent rhythm the balls were seen to be making progress, an oscillating progress, toward the pylorus; for they went forward each time a little farther than they returned. Sometimes twelve minutes elapsed before the balls had advanced to the pylorus from the place where they were first

Fig. 1.—Radiograph of a cat's abdomen, taken 5¾ hours after eating. Spinal column in middle line with pelvis below. On right, above, the pyloric end of stomach; on left, dimly outlined by gas, the ascending colon, and the cecum containing small amount of food. Loops of small intestine containing food in various parts of the abdomen.

affected by the waves; since the waves were running at the rate of six per minute, these little pieces of food were moved back and forth on their way to the pylorus more than seventy times.

The significance of the motions of these food particles is made clear when the conditions attending the formation and passing of a peristaltic wave are considered. As a constriction occurs, the secreting surface enclosed by the narrowed muscular ring is brought close around the food lying within the ring. As this constriction passes on fresh areas of glandular tissue are continuously pressed inward about the narrow orifice; and, furthermore, as this constriction passes on, a thin stream of food is continually forced back through the orifice and thus past the mouths of the glands—a food stream sweeping in one direction past an ever-refreshed mucous surface moving in the opposite direction. The result of this ingenious mechanism is that every part of the secreting surface of the pyloric portion is brought near to every bit of food before the latter leaves the stomach, it may be seventy times or more, as shown by the moving balls.

The propelling function in the stomach is subserved by these same waves of constriction whenever the pylorus relaxes. Relaxation of the pylorus occurs at irregular intervals and is due to factors as yet little understood. Curiously, it allows carbohydrate food, on which the stomach does not act, to pass onward into the intestine much sooner than it releases a proteid food which the stomach can digest. Hard particles, when brought by the peristaltic waves to the pyloric sphincter, act as a mechanical stimulus and greatly prolong the periods of its contraction. Under these circumstances over and

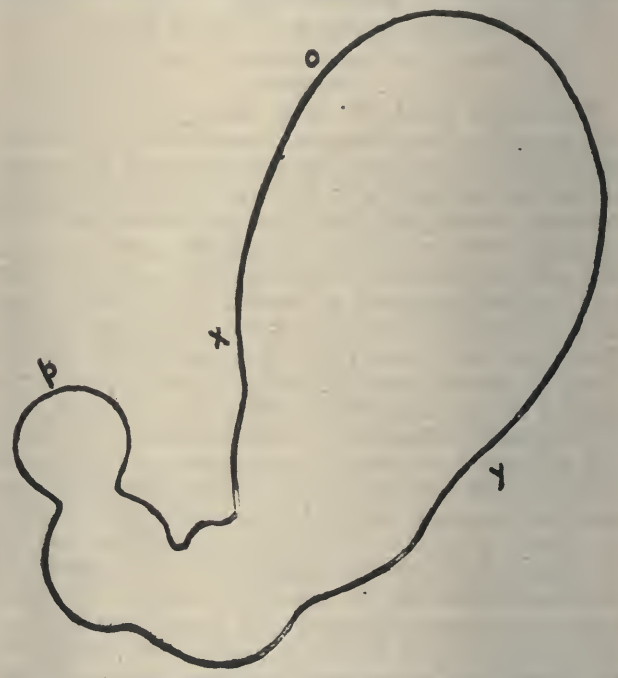

Fig. 2.—Outline tracing from radiograph of cat's stomach. *x-y*, Line of division between cardiac and pyloric portions; cardiac portion, with even contour, pyloric portion with waves of constriction passing to the pylorus (*p*); *o*, position of the œsophageal opening.

over again the hard particle is swept up to the pylorus, only to shoot back through the advancing ring of constriction. By this repeated rubbing the peristaltic waves of the stomach serve to break up the more solid parts of the food, a function which the teeth perform with manifestly greater efficiency. It may be that the prevalence of pathologic conditions in the pyloric part of the stomach rather than in the fundus is due to injuries which the greater activity of the pyloric part must bring on itself.

The fundus of the stomach, as stated above, is characterized by a slow tonic constriction of its musculature, which forces its contents into the more active pyloric portion. Pellets of subnitrate of bismuth in this part of the stomach contents retain their relative positions for an hour or more after the food is ingested. In 1898 I presented evidence that the absence of mixing currents in the fundus results in the food there retaining its original reaction for a considerable period, so that salivary digestion may readily take place in that part of the stomach without interference by the acid gastric secre-

tion. These results have recently been confirmed by Heyde[4] working in Grützner's laboratory in Tübingen.

The value of the stomach as a place for holding the bulk of the food and serving it out a little at a time so that the intestines may not become congested during their digestive and absorptive processes has been pointed out by Moritz. All the advantages secured thus to the intestines may be claimed also for the stomach itself, for, as has been shown, the active portion of the stomach is the pyloric portion, and the fundus serves as its reservoir—an active reservoir pressing out its contents a little at a time as the pyloric peristaltic mechanism is ready to receive them.

Fig. 3.—Radiograph showing region of persistent rings of contraction (descending colon), and region of antiperistalsis (cecum, ascending and transverse colon). The slight indentation above the cecum marks the position of the ileocolic valve.

I have described in detail the effects of peristaltic waves in bringing the food into intimate contact with the mucous surface of the stomach, because the action is similar to that in the cecum and in the ascending and transverse colon, where the normal activity is an antiperistalsis. Constriction waves start in the transverse colon and pass backward toward the cecum. These waves, unlike those of the stomach, do not run in continuous rhythm; they occur usually in periods lasting about five minutes and recur every fifteen or twenty minutes.

The antiperistalsis in this part of the large intestine seems indeed to give a reason for the presence of a valvular structure at the entrance of the small intestine into the large. Hundreds of antiperistaltic waves have been seen coursing toward the cecum, and only twice has food been observed to be pressed back into the ileum through the ileocolic valve. Inasmuch as the valve is competent for the food which has gone from the small into the large intestine, the antiperistaltic waves have the same effect here as the peristaltic waves have in the stomach when the pylorus remains closed. For, when a constriction occurs, some of the mucous surface of the colon becomes enclosed by the narrowed muscular ring; and, as this constriction passes on, fresh areas of this surface are continually pressed inward around the narrow orifice, while a thin stream of food is passing by it in the opposite direction. As waves recur about five times a minute, twenty-five waves or more affect every particle of food in the cecum and in the ascending colon in this churning manner during each normal period of antiperistalsis. The result must be again a thorough mixing of the contents with the digestive secretions brought from the small intestine and an exposure of the digested food to the absorbing wall.

Immediately after food passes from the ileum into the large intestine a strong tonic contraction of the cecum and the ascending colon is commonly observed, which serves to press onward toward the rectum the contents of these parts. Antiperistaltic waves follow at once the general contraction, so that much of the food which has been pressed onward is returned into the cecum. With the repetition of this process, however, more and more material appears at the end of the transverse colon, and on its appearance there a persistent ring of contraction cuts it off from the region of antiperistalsis; as still more food appears in the large intestine this ring moves slowly onward toward the rectum, pressing a mass before it, and is followed by other similar rings carrying onward similar masses by very slow peristalsis (Fig. 3).

Thus, in the large intestine the function of mixing the food with the digestive secretions and of exposing this food to the absorbing walls is performed by an antiperistalsis at the beginning of the large intestine. It is here that the last valuable constituents of the food are worked over and taken into the body. The remnant of unused material is propelled onward by occasional strong contractions of the whole region of antiperistalsis. These contractions squeeze the material toward the end of the transverse colon where slowly-moving peristaltic waves force it to the rectum.

The manner in which the food is mixed with the digestive secretions, exposed to the absorbing wall, and carried forward in the small intestine is considerably different from the processes observed in the large intestine and in the stomach. To the admirable process by which these functions are performed in the small intestine I have given the name "rhythmic segmentation." This activity of the muscular wall is first seen in the duodenum when a mass of food has accumulated there after repeated relaxations of the pylorus. The mass of food is observed at first to be wholly quiet (Fig. 4). Suddenly irregular movements take place about it, and then at regular intervals along its length constrictions of the circular musculature separate the mass into a number of segments of equal size. Hardly have the constrictions thus taken place when similar constrictions begin to appear

4. Grützner: Deutsche Medizinal-Zeitung, 1902, No. 28.

about the middle of each segment. As these new constrictions deepen, the first constrictions begin to relax. Finally, when the new constrictions have completely divided the segments, the first constrictions have entirely relaxed and the neighboring halves of the divided segments unite to form new segments in the region of the first constriction. Now these new segments are again divided by circular constrictions about their middle, and neighboring halves of these divided segments unite to make a third series, and so on. This process of rhythmic segmentation of the food may go on for several minutes in the duodenum (at the rate of thirty divisions per minute in the cat) so that the food, coming from the stomach, becomes thoroughly mixed with the outpouring secretions of the liver and the pancreas. It is usual for the process to be brought to an abrupt end in the duodenum by active peristalsis. A peristaltic wave forms behind the mass of food and sweeps it swiftly forward through several coils of the intestine.

When an animal has received a meal of bread and milk or salmon the characteristic appearance of the alimentary organs is as follows: over the pyloric end of the stomach constriction waves are continually passing.

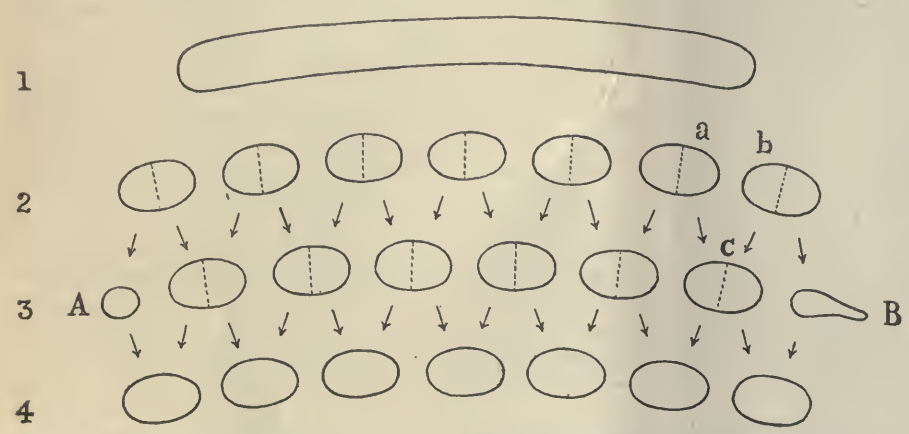

Fig. 4.—Diagram representing the process of rhythmic segmentation of the contents of the small intestine. Constrictions cut the mass into a series of uniform ovoid segments; a moment later each segment is divided into two parts, and immediately after the division neighboring parts, as *a* and *b*, line 2, rush together and merge to form new segments, as *c*. The next moment these new segments are divided to form a third series, and so on for a thousand times or more.

Along the cecum and the ascending colon an occasional series of antiperistaltic waves is to be seen, and in the small intestine a mass of food here and there is undergoing rhythmic kneading. The quiescence of the food in the intestines is in marked contrast to the continuous churning which it is receiving in the stomach. The food lies in scattered, long, slender masses in the ileum; only a few of these masses show any signs of muscular activity affecting them. When segmentation begins on one of these masses it follows the same course as that described for the duodenum. The only variations from this type are divisions of the segments into thirds instead of halves when the masses are large, or a division into two parts and the subdivision of each part before the mass is united again to undergo a repetition of the process. In the cat, as already stated, segmentation of the food occurs about thirty times in a minute. These constrictions may continue for half or three-quarters of an hour without moving the food perceptibly along the canal. The food is thus divided and redivided over and over again a thousand times or more with no advance. This same operation has been observed in the dog at the rate of from 18 to 22 segmentations per minute and in the white rat at the rate of about 44 to 48 segmentations per minute—a most remarkable activity for smooth muscle.

The result of the process of rhythmic segmentation must be a thorough mixing of the food with the digestive secretions brought from the stomach and the duodenum and with the secretions of the intestine itself, and a thorough exposure of the digested food to the absorbing walls—since, with each constriction, the absorbing mucous membrane is plunged directly into the midst of the little masses of food. Not only are the processes of digestion and absorption favored by these movements, for Mall has shown that contraction of the intestinal wall has the effect of forcing the venous blood from the submucous plexus into the radicles of the superior mesenteric vein, and has noted that it must have a similar effect on the flow of the lymph. Thus by this single mechanism of segmentation the food and digestive fluids are churned together, the absorbing mucosa is brought in most intimate contact with the digested food, and the blood and lymph, carrying the absorbed material, are sent away through veins and lacteals.

A review of the activities of the small intestine shows that the functions of mixing the food with the digestive juices and exposing the food to the absorbing structures is performed by the process of rhythmic segmentation. The function of propelling the food along the canal may also be performed to a very slight extent by this same process; it is performed typically, however, by the well-known peristaltic wave which has so long been regarded as the chief activity of the intestinal muscles.

There are two matters of practical importance which remain to be mentioned: the effect of antiperistalsis of the colon on rectal injections, and the effect of emotional states on the activities of the alimentary canal. About eight years ago Grützner[5] reported observations which indicated that materials injected into the rectum might be carried back into the small intestine even as far as the stomach. Since that time some observers have confirmed Grützner's results; others, failing to confirm them, have affirmed that such results were due to carelessly allowing the test materials to become mixed with the food which the animal took normally by mouth. The presence of antiperistalsis in the colon led me to believe that there exists here an activity which would fully account for Grützner's results. Accordingly, I injected into the large intestine enemata of different amounts and of different consistencies. The experiments showed that, when a small amount of the nutrient material was introduced, it lay first in the descending colon. In every instance antiperistaltic waves were set going by the injected mass and the material was thereby carried in considerable amount to the cecum. Never in my experience have these small enemata been carried back through the ileocolic valve. When large injections are given, i. e., amounts nearly filling the colon and cecum, the antiperistaltic waves are effective in forcing the food from the large intestine into the ileum. The ileocolic valve,

5. Grützner: Deutsche medicinische Wochenschrift, 1894, xx, p. 897.

which is competent for food coming normally from the small intestine into the large, is curiously incompetent for this injected substance, even when the substance is of the consistency of thick cream. Radiographs taken at intervals after the injection show that, as time passes, the antiperistaltic waves almost completely empty the transverse and ascending portions of the colon and that the small intestine gradually receives more and more food. After a short time the typical segmenting movements can be seen in the loops, busily separating the food into small masses and again and again dividing and redividing them. It is evident that as far as the mechanical activities of the small intestine are concerned this portion of the alimentary canal is bipolar. Food material may enter it at either end; injected food and the nutriment which has come through the stomach in the normal manner are exposed to the same mixing and absorbing activities.

Observations on the stomach of the cat, made in 1898, showed that the peristalsis is stopped whenever the animal manifests signs of anxiety, rage or distress. The extrinsic innervation of a large part of the intestinal tract is the same as that of the stomach, and it is of interest to note that emotional states have the same effect on the movements of the intestines as they have on the movements of the stomach. Any signs of emotion, such as violent rage or even the restlessness and continued whining which indicate anxiety and distress, are accompanied by a total cessation of the segmenting movements in the small intestine and the antiperistalsis of the colon, as well as the total quiescence of the gastric mechanism.

DISCUSSION.

Dr. A. C. Croftan, Chicago—To what extent did the presence of bismuth in large quantities influence these movements? I believe that some investigators deny the existence of antiperistaltic movements. I would like to ask if bismuth, which would act as a foreign body in the intestine, would modify the intestinal movements?

Dr. J. E. O'Brien, Scranton, Pa.—I have thought for a long time that many cases of appendicitis were due to loading of the cecum, and this brilliant illustration of the antiperistaltic movements of the ascending colon should shed some light on the subject. Some cases of appendicitis, I believe, begin as congestion of the cecum and extend to the appendix.

Dr. W. B. Cannon, Boston—As regards the antiperistalsis of the colon, the animals on which these experiments were performed were kept without food for a day, and I have no means of knowing what takes place except in the food containing bismuth. When food enters the colon, antiperistaltic waves may be seen coursing along the food. This may continue for about five minutes, then there will be an interval of fifteen minutes—the antiperistalsis has been seen starting from the first of the constrictions which you see in one of these photographs of the large intestine. These waves start from the end of the food as it is gradually accumulating in the cecum or the first of the tonic constrictions which occur after the food has come to the further end of the transverse colon. Nothnagel has denied antiperistalsis, but his investigations have only referred to the small intestines, and I agree with him to this extent. In the large intestine, however, there is no doubt that it takes place, for I have seen it in animals whose abdomens have been opened under salt solution. I have also seen it in the dog, and think it probably bears a relation to animals having large ceca. The bismuth does not seem to have any effect on these waves, but this is a critical matter, on which I am working at the present time. I intend adding to the food other substances which are not readily soluble, and which have a sufficient molecular weight to cast a shadow on fluoroscopic examinations.

THE CLINICAL MANIFESTATIONS OF HYDROPHOBIA.*

D. J. McCarthy, M.D., and M. P. Ravenel, M.D.
From the William Pepper Clinical Laboratory (Phoebe A. Hearst Foundation), and the Laboratory of the Pennsylvania Live Stock Sanitary Board.
Philadelphia.

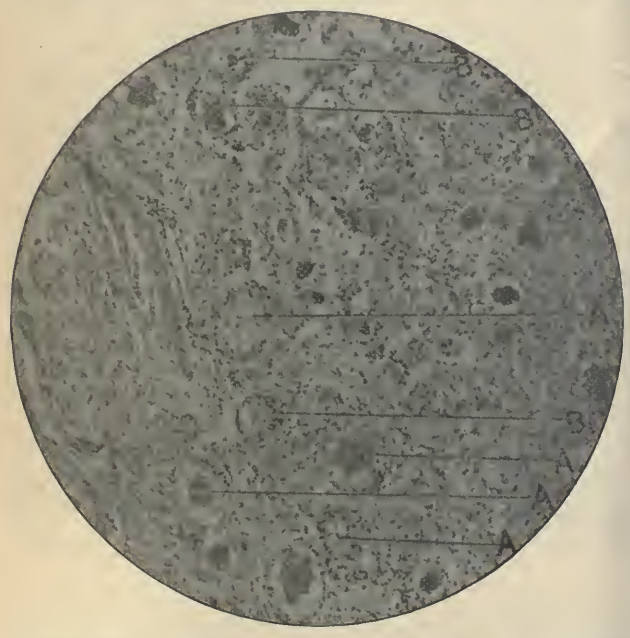
The usual text-book descriptions of hydrophobia give a clinical course of the disease divided into three stages. It is, however, difficult in practice to separate the clinical manifestations by any fixed rule.

The incubation period is usually about six weeks. In both the cases reported in this paper it was about that length. The onset of the disease is marked by several days of malaise, with slight fever, anxiety and, in a large number of cases, irritation at the seat of the infecting wound. The temperature at this stage is usually elevated one or two degrees, although it may remain at normal. This stage of irritation soon passes over to the convulsive stage. In some cases there is no convulsion or spasm, and the premonitory stage is followed by the paralytic symptoms. The symptoms of the second stage begin with more or less difficulty in the act of swallowing. Anything that excites the swallowing reflex mechanism causes an overflow spasm to the glottis, the muscles of the neck and sometimes to the jaw muscles. As the disease progresses the local spasm is replaced by a general convulsion. The mental state is one of increasing anxiety, both as to the outcome and as to other conditions, until a maniacal condition supervenes, or much more frequently the mental state of a hallucinatory delirium.

The patient may die in the convulsive stage from exhaustion and heart failure or a paralytic group of symptoms supervenes. This so-called paralytic stage may occur in cases where there is very little spasm of the muscles. In these cases it is spoken of as dumb or paralytic rabies. The paralysis is usually one beginning in the lower extremities and later affecting the other extremities. In the delirium there may be passing of the urine and stools in the bed. Some authors include among the paralytic group of symptoms the evidence of cardiac and respiratory failure.

ILLUSTRATIVE CASES.

The following two cases give a picture of the disease as it is met in private and hospital practice.



Case 1.—W. M., male, aged 5, had been perfectly well up to May 13, 1901. At that time he was bitten on the cheek by a stray dog. The wound healed and he appeared to be in good health until Saturday, June 15. During that night he cried during his sleep. The following day he was up and about, but did not appear to be well. He ate very little during the day. Citrate of potassium was administered by the mother; free purgation resulted. Sunday evening he did not appear to be able to drink, as he asked for water and then told them to take it away after attempting to drink it. Monday he was admitted to St. Joseph's Hospital, with a temperature of 101. He was very much frightened, according to notes of the case, evidently the irritative stage of the disease. He was tested as to his ability to drink, and every time he attempted to swallow there resulted a spasm of the glottis and the muscles of the neck and face. He refused to repeat the first attempt. After reassuring him, he again attempted to swallow a mouthful of water, but it came out through the nose by the spasm of the neck, throat and face muscles as in the first attempt. Later the nurse succeeded in getting him to swallow a portion of an apple. In attempt-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. A. Stengel, Winfield S. Hall and Frank B. Wynn.

ing to wash him, he became nervous when his face was washed, but was still very nervous from the tests at swallowing. At 7:30 p. m. he succeded, with much difficulty and after much persuading, in drinking 6 ounces of weak coffee. Marked spasms occurred with each mouthful of the fluid swallowed. Shortly after this general tonic convulsions ensued, the contractions of the legs being most marked. At 11 p. m. the pulse became very rapid, the patient became very restless, and in a short time delirium ensued. He imagined he saw his father under a sheet, with holes in it for eyes. The expression, which from the beginning was very anxious, now assumed a terrified aspect. At 11:15 he was pulseless, did not react to stimuli, and died at 12 m.

Autopsy.—The examination of the viscera showed nothing abnormal. The pons and medulla were markedly congested, and in some areas had the appearance as if some small hemorrhages were present.

The microscopic examination of the pons, medulla and cerebral crura showed a diffuse advanced degeneration of the ganglion cells by the Nissl method. Some of the nerve cells had entirely disappeared and in their place accummulations of deeply staining nuclei could be seen. These nuclei of Babes were more frequent in the medulla than elsewhere. Around the blood vessels of the pons and medulla large accumulations of these same nuclei were present. Capillary hemorrhages were found in the upper portion of the medulla, or under the floor of the fourth ventricle.

Section of intervertebral ganglia of the cow (Case No. 1), showing the lesions of rabies. A. Marked vacuolation and degeneration of ganglion cells. B. Advanced capsular proliferation filling up the ganglion cell capsule with the proliferated capsule cells.

The intervertebral ganglia showed marked changes. The cells were in a state of advanced diffuse chromatolysis. The capsules of all the cells showed more or less cell proliferation. Some of the capsules were entirely filled with the proliferated capsular cells. The peripheral nerves showed no degeneration.

This case is of special interest on account of its fulminating character. The patient was only sick three days. In reality only one day intervened between the development of the irritative group of symptoms and the boy's death. There were no paralytic symptoms noted. The intensity of the bulbar lesions could easily account for the rapid course of the disease. The perivascular lesions were in their extent and character more like those observed in the lower animals than those of the human being, where all the lesions, as a rule, are less in degree.

We take this opportunity of putting the following case on record:

CASE 2.—The patient was a girl, 8 years of age, who came under the care of Dr. Frederick Krauss on Aug. 12, 1900, by whom diagnosis of rabies was made, and to whom we are indebted for the history. Six weeks before, the child had been bitten on the right ear by a stray dog which she was petting because it seemed to be sick. The dog was put out of the house and lost sight of. The wound was cauterized with nitrate of silver by a druggist, and healed without suppuration. On August 11 the child complained of lassitude, but was restless, and on account of these symptoms her mother gave her a dose of castor oil. The next morning inability to swallow was observed, being attributed to "sore throat," and soon after her mother noticed that, on being touched with a wet towel or exposed to slight draughts of air, she was frightened and startled. Dr. Krauss was called in on this day. The temperature was 100, pulse 120. On giving her a glass of water, she would look at it with dilated pupils for a moment, then suddenly grasp it and quickly attempt to swallow a mouthful. Every trial was followed by severe tonic convulsive contraction of the pharyngeal constrictors and the more external muscles of the neck, lasting about fifteen seconds. Repeated attempts were made, always with the same result. In reply to a question, she said that she was not afraid of the water, but it hurt her throat very much when she swallowed it. She shrank from the slightest current of air. Large doses of bromid of potassium and chloral with morphin were given, but without effect, and the symptoms grew more marked. She passed a sleepless night. On the morning of the thirteenth her temperature was 101.5, pulse rapid. Later in the day she developed a state of intense excitement. She would lie quiet and apparently conscious for a time, then without warning suddenly spring up to her mother, crouch down with short cries of fear, looking at the wall with an expression of great dread, and seemingly unconscious of her surroundings. After about two minutes she would wake as from a dream. Repeated hypodermic injections of morphin had no effect, and she was sent to St. Christopher's Hospital. After a short remission the convulsive seizures became so frequent that almost constant inhalation of chloroform became necessary. When this was left off, she would utter short and loud cries of fear, which might well have been mistaken for the bark of a dog, and attempt to spring out of the bed. Death took place on the morning of the fourteenth, at 6 o'clock.

Autopsy.—The examination revealed congestion of the brain and meninges and minute hemorrhages, while the severity of the convulsions was proven by rupture of the pleura. The train of symptoms left no doubt in the mind of the attending physician that the case was one of hydrophobia, and the diagnosis has been abundantly confirmed by the inoculation of rabbits, as well as by microscopic examination of the bulb and plexiform ganglia of these animals. The inoculations were carried through four generations, the rabbits all dying with typical symptoms of rabies, with the exception of one of the first generation, which died thirty-six hours after inoculation from septicemia. Besides the microscopic examination mentioned, full series of cultures were made, with the object of detecting any accidental infection during inoculation or after. These cultures remained sterile in every instance, so that we are able to exclude with certainty any known bacterial disease.

The clinical and microscopic evidences so far presented in connection with hydrophobia (human being) gives us as much right to regard it as a distinct clinical entity with a distinctive pathology as we have to regard syphilis or tuberculosis as distinct diseases.

EXAMINATION OF ANIMALS WITH RABIES.

We have had submitted to us for examination 105 animals suspected or known to be rabid, including 28 cases reported to the Pathological Society of Philadelphia Jan. 10, 1901. Of these 75 were dogs, 11 cows, 2 horses, 2 cats and 15 rabbits (experimental).

One of the cows and all of the rabbits were experimentally infected. In 83 cases the clinical symptoms

and history were positive of rabies. Many of the dogs were sent to the Veterinary Hospital of the University of Pennsylvania and were under observation from one to three days before death. Forty cases were controlled by the inoculation of rabbits, a few being carried through four generations. In 60 both the medulla and the intervertebral ganglia were examined. In 36 cases only the ganglia were examined, in 7 cases only the medulla. In 2 cases neither could be examined.

In only two cases have we failed to find the lesion of Babes in the medulla when the changes in the ganglia were marked, but in several the bulbar lesion was slight. The vascular tubercle of Babes is much more often found than the one having the nerve cells as a starting point. While the vascular tubercle is frequently found accompanied by very slight changes in or about the nerve cells, we have not seen a case in which the reverse was true.

Of the 75 dogs examined 22 were killed and 53 died. In 44 the type of the disease was furious, in 9 paralytic and in 22 mixed or not reported. We have examined those animals which were killed with especial interest, since in practice we are asked to give a rapid diagnosis in a large number of such cases. The studies of Cuillee and Vallee in France have shown that in dogs experimentally inoculated, then killed at various times after symptoms of rabies have appeared, the changes in the ganglia may not be found, hence the advice is given to allow the disease to run its course, ending in death. Of the 22 dogs which were killed, in 7 we could give no opinion. In 3 of the 7 both the medulla and ganglia were examined. The importance of allowing the animal to die is manifest from this, since in at least one-third of the cases where the animal is killed prematurely no diagnosis can be made except by inoculation with the attendant delay.

The value of the microscopic method is shown in the fact that in 87 of our 105 cases we were able to give a prompt diagnosis by examination of the ganglia alone, and in 94 by the ganglia or medulla.

In view of the fact that changes in the ganglia somewhat similar to those found in rabies have been described in other processes—endothelioma (Speller), diphtheria (Crocq), chronic alcoholism (Burr and McCarthy), forage poisoning (McCarthy and Ravenel)—the clinical history should always be taken into consideration in making the diagnosis. We know of no acute disease in dogs presenting the proliferation of the capsular cells and the tubercle of Babes, and would consider them as diagnostic of rabies in conjunction with a history of an acute clinical course of the disease.

DISCUSSION

ON THE PAPER OF DRS. M'CARTHY AND RAVENEL.

Dr. Louis C. Ager, Brooklyn—I had a case in the winter, a man bitten by a dog supposed to be mad. The dog was sent to the Pasteur Institute and the diagnosis of hydrophobia confirmed. After treatment at the institute the man came home, on a Friday, and on the following Sunday he was taken sick with nervous symptoms and finally developed a double facial paralysis. Sensation was not affected. He finally recovered, and is now a well man. I have always been curious to know whether this was due to the treatment.

Dr. Leo Loeb, Chicago—Lesions have been found in other diseases similar to the ones described in rabies. To judge from our experience with other toxins we would not expect a certain histologic change to be absolutely characteristic for the action of one poison. But for practical purposes, if all circumstances are taken into account, this method seems to be sufficient.

Dr. M. P. Ravenel, Philadelphia—Among our control cases have been a considerable number of animals which had been used in testing diphtheria and tetanus antitoxins. Many of these animals had lived for a considerable time after showing the symptoms characteristic of the poisons. Animals poisoned by diphtheria toxin were selected because Crocq has found in one case of membranous croup in a child changes similar to those described by Van Gehuchten and Nélis. In none of the animals examined did we find any lesions at all like those seen in rabies. We have also examined a number of cases of distemper in dogs, a disease in which there is often a slow paralysis of the hinder extremities, and several cases of chorea, also in dogs. In none of these have we found similar changes. While we do not hold that these lesions are pathognomonic of rabies, we feel assured that, taken in connection with the clinical history, they are absolutely diagnostic.

In man some four cases have been reported in which changes similar to these have been found, but none of them could possibly have been mistaken for rabies. In the lower animals, in spite of the large number of examinations made by others, as well as by ourselves, I know of but two instances in which changes which could have been mistaken for those of rabies have been found. Both of these were in animals which died of forage poisoning; one a calf, in which the changes were very slight, and the other a horse, which showed well-marked lesions. The lesion is, however, not at all constant in this disease, for we have found it only twice, though many cases have been examined.

As far as dogs go—and this is the animal in which we are most interested in this connection—we have yet to meet with the first case in which there is the slightest reason to suspect that the microscopic findings have led us astray. The experience of two years, amounting to 105 cases, controlled by a large proportion of inoculations, as well as the study of clinical histories and the examination of animals dead of various other diseases, has convinced us of the great diagnostic value of the gangliar lesion discovered by Van Gehuchten and Nélis.

Dr. W. Becker, Milwaukee, Wis.—Three months ago I performed an autopsy of this kind and made an examination of the spinal cord and ganglia. The only change I noted in the spinal ganglia was a slight tendency toward washing away of the border of the nucleus, and the nucleolus was not as distinct as in normal spinal ganglia. Nessl's bodies were not much affected except the outlines, which were a little indistinct. All I found was a hyperemia, which is hard to diagnose in the spinal cord, this hyperemia extending upward from the dorsal region to the beginning of the cervical enlargement. There was little cellular proliferation around the blood vessels. The changes were not identical with the specimens shown here. I have performed many experiments with diphtheria toxin, and have gotten results similar to those obtained with tetanus toxin, and in neither of these cases was there anything characteristic of the lesions shown here.

Dr. E. R. LeCount, Chicago—How long would it be safe to let dogs live when you wish to make a diagnosis of rabies? Are there any cases of dogs recovering? I would remind the section that last year at St. Paul Dr. Ohlmacher showed some beautiful specimens illustrating the processes described.

Dr. M. P. Ravenel, Philadelphia—I have never seen a dog live more than three days after the diagnosis is wished for, and usually the time is not so long, so that we can afford to let the dog die of the disease. I have sometimes allowed persons to kill a dog in the last stages of the disease after the paralysis was well marked, and had no trouble in making the diagnosis thereby. There are on record only three or four cases of recovery from rabies in the lower animals. It is an extremely rare thing. If a dog is killed prematurely we may fail to find the characteristic lesions of rabies, and yet we can not exclude rabies, since sufficient time for the production of the changes was not allowed. In such a case it is impossible to say whether the dog was mad or not. The great point is that when these lesions are found we can say with absolute confidence that the dog was rabid, but their absence in a dog killed prematurely does not justify us in saying that the animal was not rabid. In all cases it is well to allow the dog to die of the disease when a rapid diagnosis is demanded.

Dr. D. J. McCarthy, Philadelphia—In reference to the case which suffered with nervous symptoms and took the Pasteur treatment, I have nothing to offer. I should suppose that it was due to the antitoxin or the treatment itself, but I confess that in a case like this I would not like to offer a positive opinion. As to the matter of these lesions occurring in other conditions, I merely did the microscopic work relative to the neuropathology. But I can say that we have never come across lesions in the intervertebral ganglia in other conditions exactly similar to those of hydrophobia. I reported a case of multiple neuritis with Dr. Burr, in which these capsule cells had proliferated and there was a multiple neuritis, but the lesions were not the same and were without round cell infiltration. The grouping of the cells was in the interstitial tissue rather than in the capsule itself. From *a priori* reasoning we expected to find these lesions in other acute conditions, but as yet we have not found them, except in the isolated cases of epidemic forage poisoning in horses and in the case of diphtheria reported by Crocq.

THE PLANTAR REFLEX IN EPILEPSY, WITH SPECIAL REFERENCE TO THE BABINSKI PHENOMENON.*

J. M. KENISTON, M.D.
MIDDLETOWN, CONN.

There is a wide diversity of opinion among writers and observers as to the nature and variety of the reflexes in epilepsy with brief, if any, allusion to the plantar reflex, which apparently either escaped observation or was not recorded until within a comparatively recent period. I find no reference to the subject by Gray or Dercum. Dana[1] says: "Immediately after the attack there is a temporary exhaustive paralysis with loss of knee-jerk." Hare[2] says: "Reflexes are decreased or lost in epilepsy immediately after an attack." Osler[3] states that "after the attack the reflexes are sometimes absent; more frequently they are increased and the ankle clonus can generally be obtained." Strümpell[4] says: "The cutaneous reflexes are still suspended directly after an attack; but the tendon reflexes are generally somewhat exaggerated, although sometimes they are diminished or absent."

Gowers[5] states that "for a few seconds after a severe fit reflex action in the limbs remains absent. Tickling the sole no longer causes a movement of the leg, and the loss may involve the muscle-reflex action, so that the knee-jerk can no longer be obtained, as Westphal first showed. But this stage of loss is succeeded by temporary increase of myotatic irritability, so that the knee-jerk is excessive and the foot clonus may be obtained. In most cases this increase is alone to be detected. It may be present only on the side on which the convulsion was most severe, i. e., on the side toward which the head is turned. It lasts a few minutes and then passes away. These phenomena are probably the result of temporary exhaustion of the centers concerned—of the muscle-reflex center in the case of loss; of the controlling structures (the terminations of the pyramidal fibers) in the case of excess." Bevan Lewis[6] says that "certain seizures are invariably followed by exalted knee-jerk and well-marked ankle clonus, the latter immediately succeeding or following a few minutes after the fit. In contrast there are instances where the knee-jerk is completely lost after a severe fit, reappearing slowly in the course of four or five minutes." He does not mention the plantar reflex.

Collier[7] in 40 epileptics found the extensor reflex present in 38 cases and absent in 2 cases. After every fit of severe convulsions, lasting any length of time, the extensor response was found and lasted for some time. In a patient who had fourteen severe fits in forty hours the extensor response was always present, persisting for seven hours after the last attack, when the flexor response returned. Walton and Paul[8] found the plantar reflex absent in 7 out of 18 cases tested. Eskridge[9] in 100 cases of epilepsy found the "plantar reflex present in 93 and absent in 7. In 21 cases subsequently observed the flexor response was present in 18 cases and irregular in 3. In reply to a letter of inquiry in regard to the "irregular" response, Dr. Eskridge writes:* "The irregularity consisted in the plantar reflex being neither distinct extension nor flexion. In neither was there a distinct extensor reflex, or Babinski sign, but there was a flexion of the outer toe generally, and in some, one or two, the smaller toes only would flex. The cases were not observed directly after a seizure, but during the interval, when the patient had resumed his normal condition. I have not had an opportunity since I have been observing the plantar reflex to investigate for the presence or absence of the Babinski sign immediately after the convulsions. In most cases of epilepsy where plantar reflex has been present it has been flexion in character; in many cases of epilepsy plantar reflex has been absent. When the patients have been on full doses of bromids the plantar reflex has been invariably absent and usually the knee-jerks also."

Oppenheim[10] does not allude to the plantar reflex in epilepsy, but says "the reflexes are abolished during the attack, and the loss of reflex excitability may last somewhat longer than the attack." It is interesting to quote in full his description of the plantar reflex. "By this term we understand the phenomenon in which excitation of the sole of the foot produces a movement in which the foot is suddenly drawn back. Naturally every form of excitation may produce this movement—touch, hot or cold applications, tickling, etc. The stronger the stimulation the stronger the reflex. The common form is a dorsal flexion (extension?) of the foot and toes; a plantar flexion occurs rarely. A contraction of the tensor fasciæ latæ may be produced by excitation of the sole. In extreme cases not only the foot, but the whole limb may be drawn back by flexion at the hip and knee. The intensity of the reflex varies. Many persons show a response only to very strong excitation, as deep pricking with a needle. Considerable variation exists among individuals as to their sensitiveness to tickling and the reflex produced thereby. We can increase the intensity of a reflex by prolongation of the stimulus or rapid repetitions of single excitations."

L. Pierce Clark[11] says: "Since the discovery of the cortical motor area and the pyramidal tracts it has been generally admitted that without the cortex there can be no epilepsy, and the impulses from the cortex must travel to the peripheral nerves along the pyramidal paths, but beyond this nearly everything is still in dispute, and the investigations of different workers are so variant as to make it impossible to harmonize their conflicting views and researches. Cestan and Le Sourd discuss at length the clinical value of the "toe phenomenon" of Babinski, and give the result, among other diseases of the nervous system, of examination of a number of cases of epilepsy. Babinski maintained that there was a close clinical connection between the toe

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

* Feb. 2, 1901.

phenomenon and "spinal epilepsy," mainly because the toe phenomenon showed as the first symptom of pyramidal involvement in disease of the nervous system. Cestan and Le Sourd therefore hold with Babinski that in partial epilepsies dependent upon organic changes in the pyramids the toe phenomenon is of great importance in diagnosis. This is especially valuable when we remember that even now may organic lesions upon which the so-called idiopathic epilepsies really depend go unrecognized because of the great difficulties which surround their detection."

Beevor[12] states that "the plantar reflex was absent immediately after the clonic stage, but returned in from three to thirteen minutes, the average lapse of time before its return being five minutes. Observations were made on 70 in 31 different cases, 47 immediately after the paroxysm and 23 shortly after."

Since October, 1899, the writer has examined the plantar reflex in 35 insane male epileptics under his care, making in all 1,088 tests directly after a seizure, as soon as clonus had ceased, and an equal number one hour later. In 6 cases epilepsy was congenital; in 3 it had lasted for from one to five years; in 2, from five to ten years; in 7 from ten to fifteen years; in 7 from fifteen to twenty years, and in the remainder over twenty years. Cases of grand mal only were tested.

Numerous examinations on each patient were first made at long intervals—one to three days—after a seizure, in order to establish the form for each individual as a basis for comparison. During the tests no bromids or other drugs were used, and a reasonable period was allowed for elimination when they had previously been taken. My chief aim in making these investigations was to ascertain how often the Babinski phenomenon was present; first, in the intervals; second, directly after a seizure, and third, one hour later. Attendants were carefully trained, and no test was accepted until I was absolutely sure that they were competent to observe and record exactly what happened—no more and no less. The interest they displayed and their proficiency are here gratefully acknowledged. Many of the tests were made by the writer personally and many more under his direct supervision.

Certain precautions were insisted upon. The feet must be dry and warm, and shoes and stockings removed before the clonus had ceased, in order to avoid delay. The patient's muscles must be perfectly relaxed and mental repose complete. A smooth stick with a blunt end was used and a deliberate and even stroke, made with moderate pressure from heel to ball of foot, along the outer part of the sole.

Morton Prince[13] says: "One cause of the discrepancies in reported observations is that there may be two distinct plantar reflexes, one of which is probably cerebral and one spinal. The normal cerebral reflex is generally, if not always, extension of the toes with the same movements (i. e., extension) of the foot. If precautions are not taken the cerebral reflex may mask the spinal reflex and give erroneous results; that is, override the spinal flexion (normal plantar reflex) and produce an extension." It is needless to say that the cerebral reflex, which also includes the withdrawal of the foot and active movements of the leg, was always excluded from my tests.

In the cases where the extension response is recorded there was a deliberate extension of the great toe, more or less marked, usually with separation of the four outer toes. Occasionally only the two outer toes were separated, the other two (second and middle) not moving. In a very few cases there was no response in any of the four outer toes. In no case was there flexion of any of the outer toes with extension of the big toe. In all cases where the extensor response was present there was dorsiflexion of the ankle, usually of moderate extent, and occasionally a temporary increase of the plantar arch. In two cases it was very difficult to secure mental repose and consequent complete muscular relaxation, thereby inhibiting the cerebral reflex. Hence, all observations where these conditions were not completely fulfilled were rigidly excluded.

Here follows a brief abstract of the thirty-five cases, with reports of two autopsies.

CASE 1.—Farmer, aged 41, epilepsy congenital; type, grand mal. Has occasional stupor lasting from four to fourteen days. Intervallary reflex; both feet flexor,* with an occasional extensor response in left foot. Knee-jerks very active; 32 tests. Results after fits: both feet negative, 9; both feet extensor, 4; right negative, left extensor, 2; both feet flexor, 3; right flexor, left negative, 5; right flexor, left extensor, 9. One hour after: both feet negative, 1; both feet extensor, 2; both feet flexor, 17; right flexor, left negative, 2; right flexor, left extensor, 10.

Here there was complete abolition of plantar reflex in 28 per cent. of tests after a seizure, and in only 3 per cent. one hour later. The intervallary reflex (in this case the normal one) was present in 9.4 per cent. after seizures, and in 53 per cent. one hour later.

CASE 2.—No occupation. Age 23; epilepsy at 19, after a fall. Type, grand mal. Has had occasional dreamy states, and during past three months has been in a stupor, with spastic gait and rather rigid muscles. 65 tests. Intervallary reflex is flexor in right foot; extensor in left; knee-jerks exaggerated. Results after fits: both feet negative, 35; both feet extensor, 19; right extensor, left negative, 3; right negative, left extensor, 4; both feet flexor, 2; right flexor, left extensor, 2. One hour after: both feet negative, 13; both feet extensor, 11; both feet flexor, 14; right flexor, left negative, 8; right flexor, left extensor, 16; right negative, left extensor, 3. In four tests stroking of left foot produced extension of big toe on right foot (crossed plantar).

Here there was complete abolition of plantar reflex in 53.8 per cent. of tests after a seizure, and in 20 per cent. one hour later. The intervallary reflex (right foot flexor, left extensor) was present in only 30 per cent. after a seizure, and in 24.6 per cent. one hour later.

CASE 3.—Age 23; no occupation; father died insane. Traumatic epilepsy, due to blow on head in left temporal region at 10. Quiet dementia. Seizures very infrequent; grand mal. Intervallary reflex is flexor, both feet, rather slow, with absent knee-jerks. Only three tests made. Results after seizures: both feet extensor, 1; both feet flexor, 2. One hour after; both feet extensor, 1; both flexor, 1; both negative, 1.

In this case there was some kind of reflex after each seizure, and abolition in one foot only one hour later, or 33.3 per cent.

CASE 4.—Age 19; no occupation. Epilepsy began at 13; grand mal; 24 tests. Intervallary reflex: both feet flexor; knee-jerks very active. Results after fits: both feet negative, 23; right negative, left extensor, 1. One hour later: both feet negative, 1; both feet extensor, 6; both flexor, 9; right flexor, left extensor, 8.

Here there was complete abolition of plantar reflex in 96 per cent. of tests after a seizure, and in only 4 per cent. one hour later. The intervallary reflex was present in no case after a seizure, and in 37.5 per cent. one hour later.

CASE 5.—Barber, aged 68; alcoholic epilepsy; onset at 48; seizures very infrequent; grand mal; 3 tests. Intervallary reflex, mixed form, extension predominating. Knee-jerks active. Results after fits: both feet extensor, 1; both feet flexor, 2. One hour later; both feet negative, 1; both extensor, 1; both flexor, 1.

* In all the cases, as well as in the table, etc., it should be understood that the words "feet" or "foot flexor, extensor," etc., mean a flexion or extension of the *toes*; negative—no response.

CASE 6.—Farmer, aged 38. Epilepsy developed between five and ten years of age; grand mal; 75 tests. Intervallary reflex, mixed form—sometimes flexor, sometimes extensor in either or both feet.

Results after fits: both feet negative, 37; both feet extensor, 10; right extensor, left negative, 3; right negative, left extensor, 8; right flexor, left negative, 3; right negative, left flexor, 7; right extensor, left flexor, 2; right flexor, left extensor, 5. One hour later: both feet negative, 31; both feet extensor, 11; right extensor, left negative, 2; right negative, left extensor, 2; both feet flexor, 2; right flexor, left negative, 2; right negative, left flexor, 1; right flexor, left extensor, 24.

Here there was complete abolition of the plantar reflex in 49.3 per cent. of tests after seizures, and in 41.33 per cent. one hour later. The intervallary reflex occurred in 50.7 per cent. of tests after seizures, and in 55.67 per cent. one hour later.

CASE 7.—Farmer, aged 50; epilepsy at 25; grand mal; seizures very infrequent. Has occasional furor and equivalents; 11 tests made. In the intervals there is complete absence of plantar reflex and knee-jerks. Results after fits: both feet negative, 10; right foot flexor, left negative, 1. One hour later: both feet negative, 4; both feet flexor, 3; right flexor, left negative, 3; right flexor, left extensor, 1.

Here there was complete abolition of plantar reflex in 90 per cent. of tests after seizures, and in 36 per cent. one hour later.

CASE 8.—Age 26; no occupation. Epilepsy began at age of five months. Patient is practically an imbecile. Seizures very frequent; grand mal; 14 tests. Intervallary reflex: flexor in one foot, usually the right; absent in the other; knee-jerks moderate. Results after fits: both feet negative, 6; both feet flexor, 3; right flexor, left negative, 1; right flexor, left extensor, 4. One hour later: both feet negative, 8; both feet flexor, 5; right flexor, left negative, 1.

Here there was complete abolition of plantar reflex in 43 per cent. after fits, and in 57 per cent. one hour later.

CASE 9.—Factory employe, aged 33. Epilepsy appeared at 22; has occasional stupor; 39 tests. Intervallary reflex: usually right foot extensor, left flexor; occasionally extensor in both feet; knee-jerks moderate. Results after fits: both feet negative, 22; both extensor, 9; right extensor, left negative, 3; right negative, left extensor, 3; right flexor, left extensor, 2. One hour later: both feet negative, 5; both feet extensor, 8; right extensor, left negative, 1; both feet flexor, 7; right flexor, left negative, 2; right flexor, left extensor, 16.

Here there was complete abolition of plantar reflex in 56.4 per cent. after seizures, and in 12 per cent. one hour later. The usual intervallary reflex was found in no case after seizures or one hour later.

CASE 10.—Mechanic, aged 34; epilepsy developed at 21; grand mal; 102 tests. Intervallary plantar reflex: flexor in one or both feet; knee-jerks moderate. Results after fits: both feet negative, 78; both feet extensor, 1; right extensor, left negative, 3; right negative, left extensor, 2; both feet flexor, 2; right flexor, left negative, 11; right negative, left flexor, 2; right flexor, left extensor, 3. One hour later: both feet negative, 34; both feet extensor, 7; right extensor, left negative, 6; right negative, left extensor, 5; both feet flexor, 4; right flexor, left negative, 37; right negative, left flexor, 2; right flexor, left extensor, 7.

Here there was complete abolition of plantar reflex in 76 per cent. of tests after seizures, and in 33 per cent. one hour later. The intervallary reflex was present in 14.7 per cent. after seizures, and in 42 per cent. one hour later.

CASE 11.—Plumber, aged 48; onset of epilepsy at 20 following left hemiplegia. Measurements of limbs as follows:

	Right.	Left.
Arm—length	37.5 c.m.	38.3 c.m.
Arm—circumference	33.7 c.m.	28.6 c.m.
Forearm—length	25.4 c.m.	23.4 c.m.
Forearm—circumference	29.9 c.m.	26.0 c.m.
Hand—circumference	21.0 c.m.	19.7 c.m.
Thigh—length	53.5 c.m.	53.5 c.m.
Thigh—circumference	57.8 c.m.	50.8 c.m.
Leg—length	38.8 c.m.	38.2 c.m.
Leg—circumference (calf)	36.2 c.m.	31.2 c.m.
Ankle—circumference	24.7 c.m.	24.7 c.m.
Foot—circumference (arch)	24.7 c.m.	24.7 c.m.

Patient has no use of left hand, which shows marked wrist drop with flaccid contractures of fingers, but can swing arm from shoulder. Left foot shows marked pes cavus. Patient swings and partially rotates left foot in walking, bringing it to the floor with a sudden flap. Character of seizures, grand mal, very severe, and average 1-1.8 days; 29 tests made. Aura; dazzling of eyes, and everything seems to be in motion, and a chill comes over left side of body. Convulsions begin by a shaking of the right hand; then a wild cry is uttered and he falls to the floor; convulsions pass rapidly down right side to foot, causing it to turn inward, and then pass over to left side, where they are most severe. Clonus lasts about three minutes, is followed by stupor for about five to ten minutes, when he arises, and resumes his seat as if nothing had happened. Intervallary plantar reflex; right foot flexor, left (paralyzed) foot, a marked extensor. Results after seizures: both feet negative, 13; right flexor, left negative, 9; right flexor, left extensor, 4; right absent, left extensor, 3. One hour later: both feet negative. 15; right flexor, left extensor, 5; right flexor, left negative, 4; both feet extensor, 1; both feet flexor, 1; right negative, left flexor, 3.

Here there was complete abolition of plantar reflex in 45 per cent. of seizures after fits, and in 51.7 per cent. one hour later. It is interesting to note that the usual intervallary reflex—right flexor, left extensor—was present in four tests out of twenty-nine, after fits, and in five one hour later. There was an extensor response in left foot only in three other tests after fits, and one hour later an extensor response in both feet. There was never any flexor response in left foot after seizures, but it occurred in four tests one hour later. Why there should be a flexor response in the paralyzed foot I am unable to explain.

CASE 12.—Age 32; no occupation. Onset of epilepsy during first dentition. Seizures have continued ever since at pretty regular intervals, with steadily progressive mental deterioration. Has periodical excitements when he stutters and repeats phrases, etc. (word clonus). Seizures usually nocturnal; only seven day-seizures in past three years; 74 tests. Intervallary plantar reflex; flexor response in both feet; knee-jerks absent. Results after fits: both feet negative, 64; both feet extensor, 1; both feet flexor, 1; right flexor, left negative, 6; right negative, left flexor, 1; right flexor, left extensor, 1. One hour after: both feet negative, 22; both flexor, 19; right flexor, left negative, 29; right negative, left flexor, 3; right flexor, left extensor, 1.

Here there was complete abolition of plantar reflex in 89 per cent. of tests after seizures, and in 30 per cent. one hour later. The intervallary reflex was present only once after seizures, and in 26 per cent. one hour later.

CASE 13.—Factory employe, aged 49; alcoholic epilepsy; onset at 36; seizures infrequent; grand mal; 42 tests. Intervallary reflex: right foot flexor, left negative; knee-jerks moderate. Results after fits: both feet negative, 23; right flexor, left extensor, 5; both feet extensor, 7; right flexor, left negative, 1; right negative, left flexor, 3; right flexor, left extensor, 3. One hour later: both feet negative, 20; both extensor, 3; right extensor, left negative, 1; right negative, left extensor, 3; right flexor, left negative, 7; right negative, left flexor, 4; right flexor, left extensor, 4.

Here there was complete abolition of plantar reflex in 55 per cent. of tests after seizures, and in 48 per cent. one hour later. The intervallary reflex was present only once after a seizure, and in 16.6 per cent. one hour later.

CASE 14.—Age 34; no occupation; epilepsy began at four. Has had repeated furors in former years, in one of which he killed a man with a blow of his fist. Now displays fluctuations chiefly in the emotional sphere, having periodical depressions when he reproaches himself, weeps, fears death is imminent, and begs piteously for a priest and his brother. Seizures severe but infrequent; 16 tests. Intervallary plantar reflex: extensor in one or both feet. Results after fits: both feet negative, 12; right negative, left extensor, 3; right flexor, left negative, 1. One hour later: both feet negative, 10; both extensor, 1; right extensor, left negative, 1; right negative,

left extensor, 1; both flexor, 1; right negative, left flexor, 1; right flexor, left extensor, 1.

Here there was complete abolition of plantar reflex in 75 per cent. of tests after seizures, and in 62 per cent. one hour later. The intervallary reflex was present in 18 per cent. of tests after fits, and in 25 per cent. one hour later. This patient once had status epilepticus—12 severe seizures, each lasting from ten to fifteen minutes with intervals varying from ten to twenty minutes. Consciousness was totally abolished, not only in the intervals, but for four hours after the last fit, and during this whole period the plantar reflex was absent in each foot.

CASE 15.—Age 28; no occupation; onset of epilepsy in "childhood." Patient is pompous and affected; writes absurd poetry; and has had several attacks of status which were always aborted by compression of the carotids. Seizures very frequent and severe; 14 tests made. Intervallary plantar reflex: both feet an active flexor, with very active knee-jerks. Results after fits: both feet negative, 5; both extensor, 1; right negative, left extensor, 1; both flexor, 1; right flexor, left negative, 2; right flexor, left extensor, 4. One hour later: both negative, 7; both extensor, 3; both flexor, 3; right flexor, left extensor, 1.

Here there was complete abolition of plantar reflex in 36 per cent. of tests after fits, and in 50 per cent. one hour later. The intervallary reflex was present only once after a seizure, and in 21 per cent. one hour later.

CASE 16.—Laborer, aged 36. Had syphilis in 1894-5, epilepsy developing soon after. No focal symptoms. Has occasional dreamy states; seizures very infrequent; only 7 tests made. Intervallary plantar reflex; usually flexor in one or both feet; occasionally an extensor response in left foot, none in right; knee-jerks moderate. Results after fits: both feet negative, 3; both extensor, 1; both flexor, 2; right extensor, left flexor, 1. One hour later: both feet negative, 4; both extensor, 1; both flexor, 1; right flexor, left extensor, 1.

CASE 17.—Farmer, aged 51; heredity denied; cause unknown. Epilepsy appeared at 36; seizures occur in groups of four to eight, usually in one night, with intervals of about four weeks, and are very severe, being followed by profound stupor lasting from one to two days; 18 tests. In one group of four fits there was some kind of response after each; in another group of five there was a response after the second, third and fifth fit, and none after the other two. During the post-epileptic stupor the reflexes were absent in 33 per cent. of tests, and present in some form in the remainder. Intervallary reflex: extensor response in both feet usually, sometimes in right only. Results after fits: both feet negative, 15; right extensor, left negative, 2; right negative, left extensor, 1. One hour later: both feet negative, 6; both extensor, 3; right extensor, left negative, 4; right negative, left extensor, 2; right flexor, left negative, 1; right flexor, left extensor, 2.

Here there was complete abolition of plantar reflex in 83 per cent. of tests after seizures, and in 28 per cent. one hour later. There was an extensor response in either right or left foot in two tests after fits; and the usual intervallary response in 39 per cent. one hour later.

CASE 18.—Age 27; no occupation; grandfather insane; paternal great-uncle an epileptic. At age of 14 had whooping cough, and shortly after began to have epileptic seizures, which at first were nocturnal, and are so now for the most part. At times very religious, with periods of violence. Is a confirmed masturbator. Presents stigmata of degeneration—ogival palate, irregular rodent teeth, and asymmetry of skull and face. Averages 3.46 seizures daily, without bromid, the use of which, while diminishing the number of fits, makes him very irritable and unmanageable. He recovers rapidly from seizures and in the intervals is bright, alert, and keen, showing no perceptible deterioration for the past fourteen years; 84 tests. Intervallary reflex: extensor response in both feet; knee-jerks very active. Results after fits: negative, 38; both feet extensor, 9; right absent, left extensor, 5; both feet flexor, 9; right flexor, left negative, 9; right flexor, left extensor, 14. One hour later: negative, 20; both feet extensor, 3; right negative, left extensor, 1; both flexor, 31; right flexor, left negative, 22; right negative, left flexor, 1; right flexor, left extensor, 6.

In this patient we find his usual plantar reflex—an extensor response—present in only 9 out of 84 tests after seizures, and in only 3 one hour later; there was a flexor response in one or both feet in 18 and 53 cases, respectively, while the reflex was abolished in 38 and 20 cases.

CASE 19.—Laborer, aged 48; alcoholic epilepsy at 36, seizures very infrequent and usually nocturnal; 15 tests. Intervallary plantar reflex; flexion, with an occasional extensor response in left foot; knee-jerks very active. Results after fits: both feet negative, 11; both flexor, 2; right negative, left extensor, 2. One hour later: both negative, 3; both flexor, 8; right flexor, left negative, 1; right flexor, left extensor, 3.

Here there was complete abolition of plantar reflex in 73 per cent. of tests after seizures, and in 20 per cent. one hour later. The intervallary reflex was present in 13 per cent. and 60 per cent., respectively.

CASE 20.—Laborer, aged 42; epilepsy at 4. There is simple but pronounced deterioration, with infrequent transitory distempers; seizures of moderate frequency, but severe; 23 tests. Intervallary plantar reflex; an active extensor response in each foot; knee-jerks variable. Results after fits: both feet negative, 4; both extensor, 8; right extensor, left negative, 1; right negative, left extensor, 7; both flexor, 1; right negative, left flexor, 1; right flexor, left extensor, 1. One hour later; both feet negative, 5; both extensor, 8; right extensor, left negative, 3; both flexor, 4; right flexor, left negative, 1; right flexor, left extensor, 2.

Here there was complete abolition of plantar reflex in 17 per cent. of tests after seizures, and in 22 per cent. one hour later. The intervallary response (both feet extensor) was present in 35 per cent. after fits, and in 35 per cent. one hour later.

CASE 21.—Cigar maker, aged 26; onset of epilepsy at 11; has periodical transitory distempers; 44 tests. Intervallary plantar reflex; both feet flexor; very active knee-jerks. Results after fits: both feet negative, 30; both extensor, 3; right extensor, left negative, 1; right flexor, left negative, 2; right flexor, left extensor, 6; right negative, left extensor, 2. One hour later: both feet negative, 6; both extensor, 2; right extensor, left negative, 1; right negative, left extensor, 1; both feet flexor, 25; right flexor, left negative, 3; right flexor, left extensor, 6.

Here there was complete abolition of the plantar reflex in 68 per cent. of tests after seizures, and in 14 per cent. one hour later. The intervallary reflex was absent in all tests after seizures, but present in 57 per cent. one hour later.

CASE 22.—Farmer, aged 47; onset of epilepsy in childhood; has periodical transitory distemper; 16 tests made. Intervallary plantar reflex: variable, usually flexor in one or both feet, rather seldom extensor in both feet; knee-jerks moderate. Results after fits: both feet negative, 13; both extensor, 1; right extensor, left negative, 1; right flexor, left extensor, 1. One hour later: both feet negative, 3; both flexor, 13.

Here there was complete abolition of plantar reflex in 81 per cent. of tests after seizures, and in 19 per cent. one hour later. The intervallary reflex was absent after seizures, but present in 31 per cent. of tests one hour later.

CASE 23.—Farmer, aged 25; father intemperate; onset of epilepsy at 13. Besides typical grand mal he has peculiar attacks which warrant a full description. He also presents psychic equivalents in the form of brief periods of bewilderment, and occasional conscious delirium with a marked religious coloring. In October, 1898, he attacked without provocation a fellow patient, saying, "I want to kill you." Regular seizures: no aura; head and eyes draw slowly backward and to the right and then he would fall. Tonus lasted a few seconds, then the left shoulder would be elevated, the arms would lie close to side, hands clenched with thumbs between index and middle fingers, and a general clonus ensue. Clonus would be followed by a heavy sleep for two or three hours from which he could not be aroused.

In January, 1900, he averaged eight of these seizures daily for one week, when he became so exhausted that it was necessary to confine him to bed, where he remained quietly, rarely changing his position and apparently indifferent to the external world. Four days later he became very restless and exceedingly noisy at night. During the ten days that he remained in bed he had only four fits, but as soon as he was allowed to be in the ward he began to have a very peculiar kind of attack. At the beginning he would walk in a circle with diameter of about six feet, gradually going faster and faster until he fell to the floor, generally striking on his left side, with head flexed. As soon as he fell he would begin kicking with both feet and striking with his hands, or catching hold of anyone near him with a tenacious grip. During these attacks his muscles become rigid but there is no clonus. Consciousness is deeply clouded, although the eyes move as if recognizing objects. As he emerges from the attack he begins to laugh heartily, and in a few minutes gets up and has complete amnesia of all that has occurred. When the attacks occur at night he kicks around in bed for awhile and finally rolls (it is not a fall) to the floor, where he kicks very little, gets up and rattles the doorknob or raps on the door. This sort of attack was present for two months without any typical grand mal intervening, and has been noticed occasionally since. There was scarcely a day when he did not have at least one, and on some days he had four or five. In a few, consciousness was not wholly clouded and he would respond to a loud, sharp order.

Intervallary plantar reflex: right foot flexor, left extensor; reflex occasionally absent; knee-jerks moderate; 38 tests. Results after fits: both feet negative, 21; both extensor, 1; both flexor, 5; right flexor, left negative, 8; right negative, left flexor, 1; right flexor, left extensor, 1. One hour later: both feet negative, 16; both extensor, 1; both flexor, 8; right flexor, left negative, 8; right negative, left flexor, 5.

Here there was complete abolition of plantar reflex in 55 per cent. of tests after seizures, and in 42 per cent. one hour later.

All the above results were in cases of grand mal only; tests made during the peculiar attacks described above furnished variable results corresponding pretty closely to those found in the former.

CASE 24.—No occupation; age 28; onset of epilepsy at 10; occasional dreamy states; 29 tests. Intervallary plantar reflex: both feet a very active extensor; knee-jerks very active. Results after fits: both feet negative, 11; both extensor, 6; right negative, left extensor, 6; both flexor, 3; right flexor, left extensor, 3. One hour later: both negative, 9; both extensor, 13; both flexor, 3; right negative, left flexor, 2; right extensor, left flexor, 1; right flexor, left extensor. 1.

Here there was complete abolition of plantar reflex in 38 per cent. of tests after seizures, and in 31 per cent. one hour later. The intervallary reflex was present in 21 per cent. of tests after seizures and in 45 per cent. one hour later.

CASE 25.—Musician, aged 43; alcoholic epilepsy with marked deterioration, especially in memory and judgment. Seizures very infrequent and often light; 11 tests. Intervallary plantar reflex: both feet very active extensor; knee-jerks very active. Results after fits: both feet negative, 8; both extensor, 1; right negative, left extensor, 2. One hour later: both negative, 6; both extensor, 4; right flexor, left extensor, 1.

Here there was complete abolition of plantar reflex in 73 per cent. of tests after seizures, and in 55 per cent. one hour later. The intervallary reflex was present only once after a seizure, and in 36 per cent. one hour later.

CASE 26.—Laborer, aged 33; alcoholic epilepsy; seizures very infrequent, but numerous attacks of petit mal; 4 tests. Intervallary plantar reflex; mixed type; sometimes flexor or extensor in both feet, and sometimes flexor in right and extensor in left. Results after fits: both feet extensor, 2; right negative, left extensor, 1; both flexor, 1. One hour later: both feet flexor, 2; right extensor, left flexor, 1; right flexor, left extensor, 1.

CASE 27.—No occupation; age 40; had scarlet fever at 7, followed by paralysis of left side, with shortening and marked atrophy of limbs; left arm absolutely helpless. Convulsions began some time later, commencing in left side and rapidly becoming general; 16 tests. Intervallary plantar reflex; right foot flexor, with an active extensor response in left foot; knee-jerks exaggerated, more so on left side. Results after fits: both feet negative, 10; right negative, left extensor, 1; both feet flexor, 3; right flexor, left negative, 2. One hour later: both feet negative, 3; both flexor, 7; right flexor, left negative, 4; right flexor, left extensor, 2.

Here there was complete abolition of plantar reflex in 62 per cent. of tests after seizures, and in 19 per cent. one hour later. The intervallary response was absent after each seizure but present in 13 per cent. one hour later. The appearance of a flexor response in the left toes in three tests after seizures and in seven tests one hour later is interesting. The writer has, however, found similar anomalies in the reflex in several hemiplegics—not epileptic—at different times, i. e., sometimes an extensor response, sometimes a flexor and sometimes no response whatever in the paralyzed foot.

CASE 28.—Age 17; onset of epilepsy in infancy; has periodical distempers; seizures very infrequent but severe, and followed by several hours of stupor; 23 tests. Intervallary plantar reflex: right flexor, left extensor; occasionally extensor in both feet; knee-jerks very active. Results after fits: both feet negative, 21; right extensor, left negative, 2. One hour later: both feet negative, 4; right extensor, left negative, 2; both feet flexor, 11; right flexor, left negative, 3; right negative, left flexor, 1; right extensor, left flexor, 2.

Here there was complete abolition of plantar reflex in 95 per cent. of tests after seizures, and in 14 per cent. one hour later. The intervallary reflex was absent not only after seizures but also one hour later.

CASE 29.—Epileptic imbecile, aged 40; onset in infancy; seizures infrequent; 27 tests. Intervallary plantar reflex: right foot flexor, left negative; knee-jerks moderate. Results after fits: both feet negative, 25; right negative, left flexor, 1; right flexor, left extensor, 1. One hour later: both feet negative, 10; both flexor, 6; right flexor, left negative, 9; right flexor, left extensor, 2.

Here there was complete abolition of plantar reflex in 92 per cent. of tests after seizures, and in 37 per cent. one hour later. The intervallary response was absent after all seizures, and present in 33 per cent. of tests one hour later.

CASE 30.—Laborer, aged 64; alcoholic epilepsy; onset in middle life; seizures infrequent; 4 tests. Intervallary plantar reflex: flexor in one foot, the other negative; knee-jerks moderate. Results after fits: both feet negative, 3; right flexor, left extensor, 1. One hour later: both feet negative, 1; both flexor, 1; right flexor, left extensor, 2.

CASE 31.—No occupation; aged 41; a moderate drinker; epilepsy began at 23 after a severe attack of measles; seizures very frequent, averaging 1.69 daily. The bromids made him very irritable, and are seldom given; 84 tests. Intervallary plantar reflex: right foot extensor, left flexor not very marked; knee-jerks fairly active. Results after fits: both feet negative, 48; both extensor, 7; right extensor, left negative, 14; right flexor, left negative, 12; right flexor, left extensor, 3. One hour later: negative 37; both feet extensor, 5; right extensor, left negative, 7; right negative, left extensor, 3; both flexor, 8; right flexor, left negative, 16; right negative, left flexor, 6; right flexor, left extensor, 2.

Here there was complete abolition of plantar reflex in 57 per cent. of tests after seizures, and in 44 per cent. one hour later. The intervallary reflex was absent, not only after the seizures but also one hour later.

CASE 32.—Carriage maker, aged 54 (?); onset of epilepsy in 1883; had syphilis at age of 25-30. Has dreamy states, in one of which he lacerated his throat with a small piece of scrap-iron which he had picked up while out walking. Seizures infrequent; 26 tests. In the intervals the plantar reflex is absent; in only one out of numerous tests an extensor response was found in right foot; knee-jerks very sluggish and slight.

Results after fits: both feet negative, 19; right flexor, left negative, 3; right negative, left flexor, 2; right flexor, left extensor, 2. One hour later: both feet negative, 16; both flexor, 1. right flexor, left negative, 6; right negative, left flexor, 3.

Here there was complete abolition of the plantar reflex in 73 per cent. of tests after seizures and in 62 per cent. one hour later. It is interesting to note that in this case, where there is practically no plantar reflex in the intervals, some kind of response was found in 27 per cent. of cases after seizures and in 38 per cent. one hour later.

CASE 33.—No occupation; age 39; no history of case obtained; 37 tests. Intervallary plantar reflex: variable, with flexor response predominating; knee-jerks very active. Results after fits: both feet negative, 19; both extensor, 5; right negative, left extensor, 3; both flexor, 5; right flexor, left negative, 2; right flexor, left extensor, 3. One hour later: both feet negative, 11; both extensor, 7; both flexor, 7; right flexor, left negative, 4; right flexor, left extensor, 8.

Here there was complete abolition of the plantar reflex in 51 per cent. of tests after seizures, and in 30 per cent. one hour later. The intervallary reflex was present in 19 per cent. of tests after seizures and in 30 per cent. one hour later.

CASE 34.—Age 39; heredity unascertained; onset of epilepsy in childhood. Stigmata: ill-shaped and flaring ears, asymmetry of skull and face; narrow and high palate, and prognathism. Patient very religious, loquacious, with great tendency to detail and noisy. He had frequent attacks of moderate furor, usually following fits, but sometimes as equivalents. Seizures averaged one in two days, and were very severe; clonus began in right side of face—the eyes rolling in the same direction—and rapidly extended to right arm and leg, and then to left side. As clonus abated he would rub his right side, leg, and head. About five minutes later he would regain his feet and rush violently around the ward, screaming and resisting violently but automatically all attempts at restraint. Ofter he would whine in a peculiar manner. Consciousness was fully restored in about twenty minutes. He reacted poorly to bromids; 21 tests made. The intervallary plantar reflex was a flexor response in both feet; knee-jerks sluggish. Results after fits: both feet negative, 7; both extensor, 4; right extensor, left negative, 1; right negative, left extensor, 2; right flexor, left negative, 2; right flexor, left extensor, 5. One hour later: both feet negative, 3; both extensor, 7; right extensor, left negative, 1; right negative, left extensor, 1; both flexor, 1; right flexor, left negative, 6; right flexor, left extensor, 2.

Here there was complete abolition of plantar reflex in 33 per cent. of tests after seizures, and in 13 per cent. one hour later. The intervallary response was never present immediately after seizures, and but once only, one hour later.

Autopsy 13 hours after death. The specimens from the cerebral cortex and spinal cord were placed in the fixing and hardening solutions fourteen hours after postmortem. The cord specimens were fixed and hardened in Mueller's fluid, and those of the brain in a 95 per cent. alcohol (Nissl method) and Zenker's (eosin-methylene stain), and also in Mueller's fluid (Cox-Golgi method). The cord specimens were stained according to the Kulschitzky-Wolters method with Van Gieson's picric acid and fuchsin stain. The sections examined in the cord were taken from the first and eighth dorsal, the third lumbar, and fourth sacral segments. All of these sections presented a normal appearance. The brain weighed 1235 grams, but in all respects appeared normal from the microscopic examination. The microscopic examination of the cortex, including specimens from the right and left paracentral lobules, and from the first frontal convolution on each side, failed to disclose any apparent abnormality, except the great congestion of the blood-vessels. The cortex was not reduced in thickness, and the ganglion cells were well arranged and of normal number.

CASE 35.—No occupation; age 37; onset of epilepsy at 15; cause unascertained. About five years before death patient developed periods of stupor, lasting from three to ten days, during which his muscles were spastic, and there was complete incoördination, with static ataxia. He was usually kept in bed at these periods, but when up sat with head flexed to the limit; his hands were clenched with thumbs turned in, and arms drawn up, while one leg was crossed over the other, and swung rhythmically to and fro in an automatic manner. This swinging motion of legs was partly volitional, to all appearances. Occasionally he would walk in a zig-zag manner for a short distance, always stepping on the ball of the foot and toes, with the heel well elevated about two inches from the floor. One year before death this spastic condition became permanent, and often one could lift him as if he were a log. He always swallowed well, even to the very last. He had been completely demented for several years.

A marked ankle clonus was always present, and also a clonus of arms and legs on exertion. His knee-jerks were exaggerated to the most extreme degree, as well as the cutaneous reflexes, the plantar reflex presenting marked extension of all the toes on both sides, with separation of the four outer (a pure Babinski). The pupils were usually dilated but presented no inequalities. Seizures infrequent, but severe; 16 tests. Results after seizures: both feet negative, 15; both flexor, 1. One hour later: both feet negative, 5; both extensor, 3; right negative, left extensor, 2; right flexor, left extensor, 6.

Here there was complete abolition of the plantar reflex in 94 per cent. of tests after seizures, and in 31 per cent. one hour later. The usual intervallary response—extensor in each foot—was never present immediately after a seizure, and in only 19 per cent. of tests one hour later.

Autopsy thirteen hours after death. The technic employed in the preparation of the specimens from the spinal cord and cerebral cortex was similar to that used in the preceding case (34), except that a segment from the medulla and all of the cortical specimens were in addition stained according to the Marchi method; and the cord specimens were hardened in Zenker's and stained by the eosin-methylene blue method. After hardening in Mueller's fluid the entire cord was sectioned in gross at intervals of 1 cm. Macroscopically, these gross sections gave no evidences of patches of sclerosis. Microscopically, sections were examined from the first and sixth cervical, third dorsal, and fifth lumbar segments. None of these sections gave evidence of sclerosis in any of the columns of the cord. The anterior horn cells were normal throughout the cord; and the posterior horn cells appeared normal in the cervical and dorsal regions. In Clarke's columns the ganglion cells showed more or less marked chromatolysis, with displacement of the nucleus to the periphery of the cell body. The brain weighed 1200 grams. The pia was somewhat edematous over the vertex. Specimens of the cerebral cortex, taken from the right and left paracentral lobules and from the first frontal convolutions on each side, showed a slight leptomeningitis, a slight increase of glia cells in the superficial layer, and an alteration of the cytoplasm of the ganglion cells, which corresponds to the cell shrinkage described by Hoch. The cortex was not shrunken and the ganglion cells were of good number and arrangement. The blood vessels of the cortex were much congested.

Both autopsies were made by Dr. A. R. Defendorf.

SUMMARY.

Tests for the plantar reflex were made on thirty-five insane male epileptics and include: 1, 700 observations at varying intervals between seizures in order to establish a norm for each individual; 2, 1,088 tests made immediately after seizures, as soon as clonus had ceased, and 3, a similar number of tests made an hour later. In these 35 patients we found the individual intervallary reflex to be of the normal type—flexion of toes on both sides—in 10 cases; there was a marked extensor response (Babinski) in 7; no response whatever in 2; and in the remaining 16 cases a mixed response, i. e., right flexor, left extensor, 5; right flexor, left negative, 5; right extensor, left flexor, 2, and in 4 cases an irregular response, sometimes flexor, sometimes extensor, or

varying mixtures of flexor, extensor and negative in one or other foot, with no predominant type. The percentages were: flexor response, 28.57 per cent.; extensor response (Babinski), 20 per cent.; mixed response, 45.71 per cent., and entire absence of response in 5.71 per cent.

The plantar reflex presented even more variations from the normal type in tests immediately after cessation of clonus and one hour later, as seen in the following table, which shows nine variations.

Table showing type of plantar reflex in 35 insane epileptics:

Type.	Intervallary.	After Clonus.	Per cent.	1 hour later.	Per cent.
Extensor response on each side..	7	103	9.56	112	10.29
Right extensor, left negative....	0	33	3.04	29	2.66
Right negative, left extensor....	0	66	6.07	24	2.20
Flexor response on each side....	10	45	4.04	226	20.78
Right flexor, left negative.....	5	81	7.44	179	16.46
Right negative, left flexor.....	0	18	1.66	32	2.94
Right extensor, left flexor.....	2	3	0.27	4	0.36
Right flexor, left extensor.....	5	79	7.26	143	13.15
Irregular	4	...	....	....	....
No response in either side.....	2	660	60.66	339	31.16
Totals.....	35	1088	100.00	1088	100.00

From this table we see that there was an extensor response on the right side in 12.87 per cent. and on the left side in 22.89 per cent. of tests immediately after seizures; while one hour later the results were respectively 13.31 per cent. and 25.65 per cent. This predominance, nearly two to one, of the extensor response on the left over the right side, is interesting and noteworthy. When an extensor response was found on one side only it was more frequent in the left foot. Including all the tests we find a right extensor response 69 times, and a left extensor 312 times.

We also see that some kind of plantar reflex—flexor extensor or mixed—was found in 40 per cent. of tests made as soon as clonus had ceased and in 68 per cent. one hour later. In Case 14, as well as in two other cases where status epilepticus occurred, but not included in these observations, the reflexes were totally abolished in the intervals, and for periods after the last seizure varying from four to eight hours. In only one case (No. 7) was there complete absence of an extensor response in all tests immediately after fits. It is somewhat difficult to compare my tests, made at exact periods, with those reported by others, who leave the exact time in doubt, except Collier, who states that "after every fit of severe convulsions lasting any length of time the extensor response was found present and lasting some time." Some writers, as Eskridge, tested epileptics only in the intervals.

The appearance of a flexor response on the paralyzed side several times in two cases of post-hemiplegic epileptics (Cases 11 and 27) is interesting. If the Babinski phenomenon is never present except in pyramidal lesions, are we to assume that such lesions occur in epilepsy, or may the extensor response in the latter be due to a temporary disturbance in the pyramidal tracts on one side only or on both sides? It is certain that as far as my tests go the Babinski sign does appear on both sides at once, or on right and left side only, after some seizures, and after others we find a normal, mixed or negative response in the same patient.

In conclusion, the results of 2,176 tests of the plantar reflex in epileptics within one hour after seizure, plus 700 tests made in the intervallary periods to establish the norm for each individual, show that in any given patient the plantar reflex displays marked variations, although in each case some one type is more or less predominant. The explanation is not easy and the variations are hard to understand, but perhaps no more so than epilepsy itself.

REMARKS CONCERNING THE MANAGEMENT AND TREATMENT OF RHINOPHARYNGEAL TONSILS BY THE GENERAL PRACTITIONER.*

ROBERT C. MYLES, M.D.
NEW YORK CITY.

As teachers in the graduate schools of general medicine we should endeavor to give that instruction which our matriculants can safely make use of after returning to their homes. I know that they receive no more enthusiastic nor more frequent instruction than that concerning adenoids. I wish to address you in behalf of those children who live in the country districts, far from the larger towns, from whence it is either impossible or inexpedient for them to be taken in order that a specialist may treat them according to some of the many vaunted methods.

It is possible to teach the general practitioner to perform the various operations suggested for the removal of adenoids, but the time required for the proper instruction in the delicate practical manipulative technic of certain methods of procedure makes many of them unfeasible. Operations with the Lowenberg's forceps or some of its modifications should not be attempted by one who does not fully appreciate the amount of harm that can be done to the rhinopharyngeal tissues.

On the other hand, any general practitioner with little or no practical skill can be readily and easily taught to operate safely with the Gottstein curette or some of its modifications. When considering the subject of rhinopharyngeal tonsillotomy one must weigh the merits of the respective methods, first as to the safety to life and the prevention of injury to the other tissues; second, approximately complete removal of all the offending lymphoid masses; third, hemorrhage; fourth, the humanitarian side. The serious death rate among the cases of general anesthesia should be more carefully investigated as to the cause and percentage. The destruction of tissue, other than lymphoid, can never be determined unless we are permitted to examine macroscopically and microscopically the masses that have been removed.

In regard to complete removal, it has been demonstrated that recurrence and new growths occur after all methods of extirpation, but far less frequently after general anesthesia and the use of forceps than the other methods. As to frequency of harmful hemorrhage the curette, by its sharp-cutting edge, is more liable to cause alarming bleeding than the forceps constructed after

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. Emil Mayer, C. R. Holmes and G. H. Makuen.

the original idea of Lowenberg. When we consider the horrible suffocating struggles of a resisting child as it is being put under ether, in some cases, it would seem a mercy to remove the growths under cocain; of course, this is all done away with where nitrous oxid gas is previously administered. But it is concerning the management of the rhinopharyngeal tonsils by the general practitioner that we wish to speak.

In certain cases the general practitioner may successfully use the adenoid forceps, the snare or the finger nail, but these methods can not be so universally and favorably adopted by him as procedure by the curette. It has been my custom to urge the general physicians whom I have had the honor of teaching to use the curette after thorough cocainizing for at least half an hour; the cocain is passed on a curved cotton carrier behind the soft palate to the uppermost part of the adenoid; this is done at intervals of from five to ten minutes; the solution of cocain employed varies from 10 to 100 per cent. A 0.1 per cent. solution of cocain should be sprayed through the nose and then stronger solutions should be used on cotton carriers or through canulas passed through the nose. The child is wrapped with a sheet, which should pass around his body several times, with the hands down by the sides in soldier position; the sheet is then tightly and securely pinned from top to bottom, the child is then placed on the right knee of assistant or attendant, who embraces him firmly with arms and legs and the head is securely held by the nurse. For general use a medium-sized semi-circular shaped curette which has been well sharpened is passed upward behind the soft palate until it strikes the posterior border of the septum, then it is firmly driven upward until it strikes the vault and presses on the rostrum of the vomer. The cutting surface of the curette must be kept at right angles to a perpendicular line through the center of the head, a quick, firm movement is made directly backward and downward; usually the large mass removed consists of nearly all of the adenoid tonsil proper. The curette is reintroduced, rapid and moderately firm scrapings are made in both of Rosenmüller's fossæ and over the posterior pharyngeal wall, then the finger is introduced and any remaining masses are broken up and smoothed down.

The after-treatment consists of an immediate insufflation of a powder composed of equal parts of aristol and boric acid. The patient should be denied active exercise and should not be allowed to go where he can not be seen quickly by the operator or his assistant in case of serious bleeding.

Every student should be carefully and practically instructed in the details of tamponage of the rhinopharynx. The author has found the smallest sized urethral catheter, from which the stylet has been removed, to be the best instrument for passing the strings through the nose and mouth. The tampon should be from three-quarters to one and one-quarter inches in diameter, the age of the child determining the size, should be aseptic and antiseptic and remain in position from twelve to thirty-six hours. The earlier it is removed, other things being equal, the less the liability to an attack of otitis media acuta.

DISCUSSION.

Dr. C. R. Holmes, Cincinnati—I scarcely feel like criticising anything that Dr. Myles says. I have great admiration, as we all have, for everything he does and for his ability. But I can not quite agree with the sentiments of his paper. It has been my experience to let internes in the hospitals and my assistants operate, and I often notice they make very bunglesome efforts at operations, and if these men, who have been with specialists and have helped in operations, will leave a large part of the posterior mucous membrane hanging down as a flap, because they carry the curette too far downward and backward (and that occurs once in a while with operators who are fairly expert), if the general impression gets out that the general practitioner should do this operation there would be many unfortunate results. There are many general practitioners who can do this operation, but it is generally the one who is least competent who thinks he can do it, and it is for that reason I can not subscribe to the Doctor's idea that the general practitioner should be taught to do the surgical operation. I have made nothing like the number of operations Dr. Myles has, but I have made a few hundred, and I always make them under chloroform or nitrous oxid. I do not regard it as such a simple operation, if you do a thorough and clean operation. If it is not so easy in the hands of a man who has made several hundred operations, it is probably less so, and complications are more likely to occur, in the hands of one not accustomed to use instruments so much.

Dr. J. E. Brown, Columbus, Ohio—I have been much interested in this subject of adenoids for the past fourteen years, and have performed a large number of operations for the disease. As I look back to those operations I did ten years ago I believe I did not do as thorough work then as now. I say this to bring out the point that this operation rightly performed is not so simple a one that the general practitioner without experience can do it thoroughly. I now and then attempt an operation on young children under cocain, and frequently in these operations done in this manner I have had later to give a general anesthetic and do the more thorough operation. Dr. Richards' paper, it seems to me, brought out the point that a general anesthetic is necessary for the proper treatment of these cases. Our general practitioners should be taught that it is a procedure demanding a general anesthetic. If then they wish to attempt it without general anesthesia, all well and good, but this should not be our teaching.

We hear it stated that naso-pharyngeal adenoids should be removed when symptoms of obstruction are present. I have been much surprised in some of the cases that have come to me with symptoms of middle ear trouble, in which adenoids were present, at the immense size of the adenoid masses removed, yet in which cases there had been absolutely free nasal breathing.

Dr. Edwin Pynchon, Chicago—I have been doing this operation as often as possible without an anesthetic. I believe the fear of the child while struggling over the anesthetic is often worse than the pain of the operation. As regards the use of cocain to reduce the pain in this operation, I think its value is more fanciful than real. The use of cocain often causes almost as much annoyance as the operation itself. I find, though, that by introducing two cotton applicators, one through either nostril, and then having the patient or somebody else press them against the pharyngeal wall, I probably get as much effect therefrom as in any other way. When the forceps are used, I think it is wise to use the curette afterward. One of the disadvantages in using the curette is that a fragment drops down back of the uvula every once in a while, as suggested by Dr. Holmes. Now, why does this occur? It is because the curettes most often used, when introduced into the vault, have the cutting blade at such an angle that it is the side instead of the edge of the blade that first does the curetting, while lower down the cutting edge cuts too deeply, so a piece is permitted to fall down behind the uvula. I have had a curette so made that it cuts at the highest point and also has side cutting blades, with which the fossa of Rosenmüller on either side can be curetted.

Dr. Robert C. Myles, New York City—The paper referred especially to that class of cases that could not be seen by a specialist, and I do not know how many such cases there are. The general practitioner can remove with one movement of the curette most of the adenoid tissue. These cases are improved, even by an imperfect operation. Many of the general practitioners do the operation when they could send the case to a specialist, but I am pleading for the remote districts.

When the general practitioner attempts to use the forceps, he may do harm, but in the operation I have described he is not likely to do any damage to the adjacent tissues.

THE DEGENERATE TONSIL.*

EDWIN PYNCHON, M.D.
Professor of Rhino-Laryngology and Otology, Chicago Eye, Ear, Nose and Throat College.
CHICAGO.

Ablation of hypertrophied tonsils is a procedure which has become generally indorsed by the profession of medicine, though in earlier years its advocates were less numerous and many sturdy opponents contended that the proper course to pursue was to patiently await Nature's cure by absorption or, as most often worded, until the patient would outgrow the trouble.

It is not strange, when even physicians indorsed such practice, that patients easily became converted thereto, particularly as the natural tendency is toward procrastination in matters pertaining to health. Eventually some of the more pronounced evil results due to enlarged tonsils became so patent that procrastination was forced to give way to operative treatment, though many of the lesser evils due to this cause, not being thus recognized, were neglected, and the patient later became a serious sufferer thereby.

Through the so-called process of absorption different results and structural formations follow in different cases, and hence in later years different forms of tonsillar mal-condition are met with. I have therefore employed the term "degenerate" to cover all of the ordinary or commonly-met chronic conditions of tonsillar disease, which classification would seem warranted by the fact that the same treatment, total tonsillectomy, is equally applicable to all and offers the only absolute and permanent cure obtainable.

One characteristic feature observed in the process of degeneration is that the protrusion becomes less and less pronounced, though, when the examination is properly made, it will be found that the diminished protrusion is largely due to a transformation into submersion. In other words, the bulk of tonsillar tissue has not been so materially lessened, though through the submersion the faucial space has become enlarged, hence a superficial examination can easily give the impression that Nature's cure has been effective.

During the process of submersion there is a gradual absorption of the hyperplastic or lymphoid element, and consequently a relative hypertrophy of the follicular element of the tonsil, and this evolution, which may progress for many years, is constantly accompanied by and undoubtedly produced through a low grade of chronic inflammation generally manifested by the discharge of a cheesy secretion from the crypts which is continuously taking place, and which, when most noticeable, is known as chronic lacunar tonsillitis.

While in early life the greatest bulk of the enlarged tonsil protrudes above the plane of the faucial pillars, and in rare cases is entirely above this plane, it is a fact in a very large majority of cases, in even the youngest patients seen, that as much of the tonsil is concealed by submersion and pillar attachment as is apparent through protrusion. This fact is often revealed after an ordinary tonsillotomy, when the remaining base is clearly visible, and through the eventual enlargement of this base we can easily account for the many reported cases of reproduction of the tonsil after a tonsillotomy.

In combination with the condition of tonsillar submersion there is generally present an adhesion of the anterior pillar thereto, which pillar is often hypertrophied and extends backward so as to constitute a covering over the tonsil to which has been given the name plica triangularis, but which I am inclined to regard as an anatomic name applied to a pathologic product, it being simply a hypertrophy of the mucous membrane of the pillar. The posterior pillar is also at times hypertrophied and adherent to the tonsil, and in some cases degenerated into a tissue having the same appearance and texture as the tonsil itself.

One of the earliest writers who called attention to the deleterious effects of the enlarged tonsil when not protruding was Yearsley, who, in a brochure on "The Enlarged Tonsil and Elongated Uvula,"[1] published in London over a half century ago, emphasized the pathologic importance of and the urgent necessity for thoroughly removing such tonsils, largely on account of their bulk, and therefore their mechanical effect on the eustachian tubes, thereby being a cause for ear disease. He says: "Sometimes when only a small amount of tonsillar disease exists it will occasion thickening of the contiguous mucous membrane of the eustachian tubes" (p. 41), and "in some instances when nothing morbid was visible in the throat the upper part of the tonsils has been of such magnitude as to produce deafness" (p. 38).

It will be apropos to quote his description of the nonprotruding tonsil, which reads as follows: "There is another variety of enlargement which I am not aware has ever before been noticed; it is where the diseased growth is confined to the upper margin of the tonsil, and which, from being hidden behind the veil of the palate and the anterior palatine arch, is quite out of sight when the throat is merely examined by the eye (p. 38). . . . In many instances the induration is altogether absent and the diseased glands are so soft as to break down repeatedly if grasped by a forceps (p. 17). . . . In adults a general thickening of the mucous membrane of the throat without any particular implication of the tonsils is often observed" (p. 10). Yearsley, in place of the tonsillotome, employed an angular bistoury, bent on the flat, whereby he claimed the entire tonsil could be cleanly dissected out.

After Yearsley for many years but little attention was given to the tonsil beyond the ordinary tonsillotomy for simple enlargement. Shortly prior to 1890 Bosworth,[2] Harrison Allen,[3] Maxwell,[4] Lennox Browne[5] and Roe[6] have all described various pathologic manifestations associated with diseased tonsils when "unattended by hypertrophy," and since 1890 many medical writers have dealt with the several mal-conditions of all of the tonsillar tissues and have suggested various methods of treatment, ranging from the expectant to the aggressive.

The pathologic importance of the supratonsillar fossa as a hotbed of pyogenic organisms, and of the so-called plica triangularis, so often adherent to the tonsil, whereby follicular debris is imprisoned, has been particularly described by Paterson[7] and Hartz,[8] who, through report of cases and otherwise, have given ample proof of their instrumentality in the production of various local and systemic infections. Among American writers Winslow,[9] Emil Mayer[10] and Packard[11] have all added their evidence to this proposition, combined with arguments which should be convincing, and Ullman,[12] in an elaborate paper in which the literature of the subject is

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. Emil Mayer, C. R. Holmes and G. H. Makuen.

critically considered and 68 references cited, finds that the tonsil, being often diseased, is the "nidus for the growth and distribution of pathogenic organisms and their poisonous products in the system, and that many grave and fatal general infections have their origin therein."

It may be said, *en passant,* that the more submerged or deeply buried the base of the degenerate tonsil is the more diseased it will often be found to be. In the removal of such tonsils small, latent abscesses are frequently found at the deeper points, and their presence would naturally suggest the possible erosion of adjacent small vessels whereby infection might be drawn into the circulation and thus affect distant organs. Systemic infection also occurs through the course of the lymphatics.

Retained secretions in the supratonsillar fossa may, at any time, develop either a follicular tonsillitis, or a peritonsillar abscess, the form taken being influenced by the structural formation of the parts, or the direction of least resistance in any given case, and as the cellular tissue of the fossa often continues downward to varying distances in different subjects, a quinsy may develop at any point thus reached. In fact, the graver phlegmonous anginas are probably thus produced.

As the fossa becomes a cesspool for discharges from the superior tonsillar crypts it should, during a tonsillectomy, be thoroughly exposed and eradicated in order that the operation shall give perfect results.

Susceptibility to recurrent attacks of acute tonsillitis is probably the most annoying feature associated with chronically diseased tonsils, though a simple irritation or rawness of the throat, which goes no further, is more often observed. In fact, in a large majority of cases the patient is thoroughly unconscious of the presence of any tonsillar trouble.

The injurious effect on digestion due to the swallowing of diseased tonsillar secretions was observed by Yearsley (p. 35), and that such gastric disturbance is due to direct infection from germs in the naso-pharyngeal secretions has latterly been demonstrated by Turck.[13] Chronic bronchial catarrh as a result of drawing into the lung tubes morbific secretions from above was also noted by Yearsley (p. 35), whose teachings have been for many years apparently forgotten, though the same conclusion has, in recent years, been arrived at by others, and most notably by Ballenger,[14] who finds that catarrhal irritation of the lung tubes extends to the air vesicles and causes a thickening in the walls thereof which obstructs the osmotic action whereby the blood is both oxygenated and purified. In this way we see an explanation for impaired general health as well as for cough or asthma, should either be complained of.

As the fetid caseous tonsillar secretions, both by physical and microscopic examination, are richer in morbid material than is the usual post-nasal discharge, it seems warranted to give credit to the tonsillar secretions for the bulk of damage done the system through either the pulmonary or intestinal tracts.

Another result of the degenerate tonsil not infrequently observed is tenderness or swelling of the cervical glands. This latter symptom is regarded by McBride[15] as an urgent indication for a thorough tonsillectomy on account of the possibility of tubercular infection.

Submerged tonsillar tissue, whether the result of absorption or the aftermath of a tonsillotomy, occupies a material space, which may be roughly estimated at one cubic inch on either side, and is therefore a mechanical obstruction to vocalization, particularly as by binding together the faucial pillars free mobility of the soft palate is impaired so as to limit the maximum size of the posterior passage to the nasal chamber. Yearsley, at his early day, remarked that "when the morbid growth extends upwards and interferes with the motion of the soft palate, or encroaches on the cavities of the nose, the voice becomes nasal" (p. 23), and, furthermore, that with public speakers who are troubled with dysphonia "in nine cases out of ten the tonsils or uvula are the cause of the malady" (p. 22).

While many of the chronic diseased conditions of the tonsil possess individual characteristics under microscopic examination, the importance of differentiating the several varieties which have been described is much diminished by the fact that any and all of the simple chronic forms of tonsillar disease are equally amenable to the same treatment, viz., that of thorough eradication, and in my experience nothing less than this radical step is to be advised, as no patent argument can be advanced for the partial retention of a diseased gland, and the invariable beneficial after-results following a thorough tonsillectomy demonstrate the fact that the total loss of the faucial tonsils does not, in any way, impair the integrity of the economy.

In the examination of a throat wherein degenerate tonsils are present, a heightened color or increased redness of the fauces is first noticed, and an arched line leading downward on either side from the base of the uvula is invariably observed. This line curves downward on either side near the vertical center of the more or less hypertrophied anterior pillars, and quite clearly outlines the top and anterior edge of the submerged tonsils. The forward ends of the arched line are made more distinct by causing the patient to gag, at which time the line of demarcation between the red within and the pink outside thereof becomes more clearly visible.

While the patient is gagging the outlines of the submerged tonsil can be easily recognized through or beneath the anterior pillar, and by traction on the tonsil when grasped by a suitable forceps it can often be made to move about beneath the anterior pillar so its outlines can be seen to change. Pressure on the tonsil at this time with the finger, or with a suitable blunt instrument, will generally cause the escape of a muco-purulent secretion, or of "cheese balls," which, when flattened by pressure between the thumb nails, emit a fetid odor. Frothy saliva often covers the parts and with the new patient the fauces are generally hypersensitive, though the sensitiveness can usually be overcome by the frequent practice of a drill in faucial manipulations so that after a few days a sufficient tolerance is attained to permit of operative treatment.

As no tonsillotome yet made is efficient in completely removing the tonsil as usually met, and particularly in case of the submerged or degenerate tonsil with which this paper deals, other methods of operating have been practiced, as the use of the bistoury or the shears. It is not to be denied that a complete removal of the tonsil can be attained by either of these methods, though the unavoidable feature of hemorrhage necessarily interferes to a material degree with the thorough removal of all abnormal tonsillar tissue on account of its obscuring the field work. Additionally with the hemorrhage the anesthesia soon passes away when a local anesthetic has been employed. As the necessity for removing all of the follicular element is imperative in order to obtain the maximum benefit of the operation, I have for the past twelve years been using the electrocautery as the dissecting instrument instead of the bis-

toury, and I, in this way, obtain the following advantages, viz.:

1. A practically bloodless field so all of the diseased tonsillar tissue can be cleanly removed.

2. Owing to lack of hemorrhage no loss of the local anesthetic.

3. By the cauterization a destruction thereof should any portion of the follicular element escape the line of dissection.

The time limit will not permit of my describing in this paper the steps of the operation which has been elsewhere described at different times (see Bibliography, Nos. 16, 17, 18, 19 and 20), and which I have employed on more than a thousand occasions.

By this method of operating the tonsil generally peels out with facility, and often bloodlessly, the incisions being as though cutting through cheese, though in some cases sclerotic tissue is encountered which gives a sensation more like that of cutting leather. I might add that in the removal of an enlarged fibrous tonsil, the form of tonsil in which fatalities from hemorrhage after an ordinary tonsillotomy have been most often reported, this method of operating by "electro-cautery dissection" gives the greatest promise of immunity from that complication as the line of incision is outside of the area of sclerosis.

My results have been ideal and have generally yielded a throat with fauces pink instead of red, a throat with mobile and approximating pillars, which with vocalists has enhanced the high register by two or three notes, and a throat the tonsillar region of which is never afterward the source of pain or discomfort to the patient. Furthermore, there has generally been an improvement in the nasopharyngitis, and in the tubal catarrh should such conditions have previously existed, and the same may be said concerning gastrointestinal disturbance or chronic bronchial catarrh, and lastly with singers there has followed a diminished tendency to recurrent laryngitis. It will, of course, be understood that all deformities or troubles of the nose or nasopharynx, when such were present, were also corrected.

DISCUSSION.

DR. J. F. BARNHILL, Indianapolis—Until recently a large per cent. of the tonsillotomies, even by men in the specialty, were imperfectly done for the reason that the instruments used were nearly all some kinds of tonsillotomes. The class of cases which Dr. Pynchon described in his paper is one in which the tonsillotome can not be successfully used. If one attempts to use this instrument in such a case, he simply cuts off the top of the tonsil. I have been in the habit of classifying tonsils into two very broad divisions: one in which we remove the glands for the reason that they produce obstruction to breathing, and the second in which we remove them because they have infected pockets and are, therefore, the source of periodic or possibly constant inflammation.

Coulter removes part of a tonsil at a time, with electricity, dissecting it away. These tonsils are always adherent, and my method has been to dissect them away from the pillars, by electricity, so they can be lifted out easily, and then snare them away en masse. It is to me much easier and quicker; possibly to Dr. Pynchon it might not be. I have never followed the method of removing a part at a time and thus extending the operation over some thirty or forty days, as has been described by Dr. Coulter. I have always removed them at once and I have never had occasion to regret doing the entire operation at one sitting. I believe the value of the method described here comes not only from removing the tonsil crypts but also from the fact that we free the pillars of the fauces, which are muscular organs, and thereby we give greater freedom to the organs of voice.

DR. ALBERT H. ANDREWS, Chicago—Dr. Pynchon is the originator of this plan of operation. Dr. Coulter's description and use of the method was several years later than Dr. Pynchon's first publication of it. In the classification of chronically-diseased tonsils three divisions is all that seems necessary: first, simply inflamed tonsils; second, hypertrophic tonsils; and third, atrophic tonsils. This classification is in accord with the well-known pathologic changes resulting from chronic inflammation in other parts of the body. In the first division, the simple inflammation, the blood-vessels are congested and the tissues engorged, but there is no structural change in the tissue. In the second division there is a proliferative change in the tissue, and in the third division the connective tissue is contracted and the lumen of the vessels is lessened, and with the lessening of the blood-supply there comes atrophy. The third division is the degenerate tonsils Dr. Pynchon mentions. In removal of the tonsils I have not used the method Dr. Pynchon describes because I have not as yet had occasion to find any fault with the method I have been using. If I believed Dr. Pynchon's method better, taking all things into consideration, the pain produced and the time it is necessary to subject the patient to the discomfort of that operation, I would use his method. To my mind, however, it is not justifiable. My method is first to liberate the tonsil from the anterior and posterior pillars. I pass an angular knife down first between the tonsil and the anterior pillar. Adhesions between the tonsil and anterior pillar are usually more pronounced than between the tonsil and the posterior pillar. After the tonsil has been liberated from the pillars, I care not how deeply submerged it may appear to be, if it is caught by a double tenaculum forcep, it can be pulled outward from between the pillars and cut off. I sometimes use scissors and sometimes a tonsilotome for this purpose. As regards pain and hemorrhage, if pledgets of cotton saturated with a solution of cocain are pushed into the crypts of the tonsil and around behind the tonsil for a few moments, and then pledgets of cotton introduced into the crypts saturated with adrenalin, the hemorrhage will be exceedingly slight and the pain hardly worth mentioning. I wish to speak against the method which I would call "tonsil snatching." There is no necessity for hurry in these cases. If the patient is a child and will not hold still so you can do the right kind of operation, give him an anesthetic and operate with care. Thorough removal of the tonsil will be followed by satisfactory results, whether the removal is accomplished by scissors, tonsilotome or the galvanocautery. I was struck with one statement Dr. Pynchon made, that if portions of the tonsils were accidentally left the cautery would destroy them. If the cautery will destroy the base of a tonsil accidentally left why will it not destroy adjacent normal tissues when the entire tonsil has been removed?

DR. D. A. KUYK, Richmond, Va.—Those of us who have read Dr. Jonathan Wright's articles on the effect of the electrocautery on the nasal mucous membrane, for he says the effect of the cauterization is so great, extending so far beyond the point cauterized, entirely beyond our power to limit it to any given surface or area, would hesitate before ablating the tonsil with the electro-cautery. The large area cauterized might cause subsequent cicatricial contraction with no means in our

power to limit it, involving perhaps the palatine pillars causing perhaps alteration in vocalization that might be most unfortunate in singers, elocutionists, public speakers, etc. I have a case in point in which this very effect resulted.

Cicatrization caused contraction between the anterior and posterior pillars; they were twice severed, but recurred, the patient declined any further treatment and left with considerable impairment of the voice. This result may have been my fault, but every possible precaution was used, everything was done to stay the cicatricial contraction, but nothing availed.

Dr. William L. Ballenger, Chicago—I have seen probably 25 per cent. of Dr. Pynchon's cases, in all stages of operation, and I have seen him operate. I have seen a number five, six or seven years old, and I will say I have never seen any results that compared with those obtained by Dr. Pynchon. He gets the most beautifully clean-looking throat I have had the pleasure of looking into. There is no evidence of undue cicatricial formation. Judged by its results, it is certainly an ideal method. But I have not felt inclined to use it extensively because it requires from four to six sittings to remove two tonsils, and there is considerable inflammatory reaction in some cases; in others there is very little. If one should, in the course of the operation, burn the muscular fibers of the anterior or posterior pillars, there might be some serious complications interfering with the use of the voice. It seems to me that accident would result only from the lack of experience in the use of the method. In none of the cases I have seen has that resulted. My own method for the complete removal of the tonsils, which I prefer in adult cases and in the cases which Dr. Pynchon has denominated the submerged cases, is to dissect them out with the knife. If the adhesions are not extensive this is an easy matter. Often I find the adhesions very extensive, not only in the region of the posterior and anterior pillars but in the pharyngeal aponeurosis as well, and in some of those cases it requires considerable care to separate the adhesions. But it can be done and the tonsil removed very completely. If there are no adhesions, then the tonsil can be enucleated practically with a dull instrument, such as the handle of the knife, for instance. Dr. Beck was present when I removed a tonsil in this way. It leaves a smooth pocket and probably would give results as good as Dr. Pynchon has secured. By this method I can remove two tonsils at a sitting and save my patients and myself considerable work and some pain. I have used cocain anesthesia in this operation, the strength of the cocain solution ranging from 10 to 20 per cent. With the 20 per cent. solution, however, I have had in a few cases considerable cocain poisoning. Usually I do not use a solution stronger than 10 per cent. As a rule the patients say it does not hurt or that it hurts very little.

Tonsils are removed for other purposes than because they are degenerated or adherent or for the purpose of improving the voice. The posterior pillar is the palato-pharyngeus muscle, that is, it contains this muscle, the fibers of which extend up to the mouth of the eustachian tube and control more or less the patency of the tube, and so we may remove the tonsils to improve tubal and middle-ear disease as well as to improve the voice. Mackenzie and Curtis have said that they never observed anything but improvement of the voice from removal of the tonsils. I certainly have not, and some of Dr. Pynchon's patients who were singers, declare that they have only secured a good effect in this way. I would only say of his method that it probably requires more skill than some of the other methods, but nobody could get better results than Dr. Pynchon obtains.

Dr. J. C. Beck, Chicago—Dr. Pynchon and I work almost side by side, and have worked for two years in the same clinic. I see his cases often and know his results. I am asked by the students often about his operation, and in order to be able to answer intelligently I have done his operation a number of times. After he has operated—and he has operated on a considerable number of physicians—his patients come back and say that they have been benefited very much. That is a good while after the operation. For the first week the patients, including the physicians he has operated on, complained bitterly of the pain from the operation, whether it was done in one sitting or two. The reaction following the use of the cautery is very marked. There are symptoms of sapremia that make the patients very ill. The results from the operation, nevertheless, are good.

The Doctor removes the pillar. He says part of the pillar is degenerated with the tonsil and should be removed. I have satisfied myself that this part of the pillar has some use, and I do not remove it. It has muscular fibers in it, and I am opposed to its removal. I have seen cases the Doctor has operated on, in which the posterior pillar was very much hypertrophied, probably from taking on some of the action of the anterior pillar. Sometimes a layer of the pillar comes over the anterior surface of the tonsil and may be mistaken for the pillar, it is the plica tonsiluris, and its removal, aside from that, is a tedious, unnecessary operation. Dr. Pynchon teaches his pupils to do the operation very easily, but it requires considerable teaching of the patient so that he may hold the tongue depressor, and the constant holding and the fight they make in doing the operation sometimes is very annoying. I treat these degenerated tonsils by slitting the ducts. By this I often do not succeed, but sometimes there is very great amelioration of the symptoms. For the removal of them I use punch forceps much similar to Dr. Myles' punch, only it is square, and I excise the tonsils with knife or scissors. One thing in favor of cauterization is the prevention of bleeding. It has been said that the bleeding is not much, and that the adrenalin, etc., will stop it, but sometimes it is considerable, and if the use of the cautery will avoid this danger it is something in its favor.

Dr. G. Hudson Makuen, Philadelphia—One of the speakers has said that Dr. Pynchon advises an operation extending to the removal of a portion of the anterior pillar, but I have not understood this from his paper nor from his previous writings. The opercular fold is not a part of the pillar, although it has muscular fibers in it. It is a part of the tonsil rather than of the pillar. The removal of any portion of the anterior palatoglossi muscles would be bad surgery, for it would change their length and thus interfere with their natural functions. I would like to ask Dr. Pynchon what he does with the opercular fold, which sometimes forms a mass larger than the tonsil itself. I have sometimes removed it. It is very vascular and it contains muscular tissue.

Dr. P. J. Gibbons, Syracuse, N. Y.—Tonsils that often are removed may be treated conservatively by stripping them from adhesions to the pillars and then treating with iodin, camphor menthol or nitrate of silver. Bosworth has told us that the tonsils never will bleed too much, therefore let them bleed. Later Bosworth got up a snare for the removal of the tonsils, evidently he must have thought there was reason for it. I tried chopping everything off. But I saw some hemorrhages that were rather alarming. Then I used a tonsillotome, which I first dulled. If you are going to take out the tonsil by piecemeal, you can do it with the snare, and still better with the cautery. If you want to remove the entire tonsil with the cautery there is everything in knowing how to use the electrocautery. Of course, an inexperienced man might do a great deal of harm in this way. I would encourage a little conservatism in removing the tonsil. Sometimes it is sufficient to remove it only partially. I refer now to the small tonsil that we may retain. There is a function for everything in the body, even the appendix, more than for the surgeon to operate on.

Dr. George F. Keiper, Lafayette, Ind.—We ought always to remember, in removing the tonsil, no matter what method we use, if we get the bottom of the crypts we will accomplish everything desired in its removal. I have been doubtful in the cases of alleged total removal of the tonsil that I have seen as to whether the tonsil has been entirely ablated. I have, however, never seen any of Dr. Pynchon's results.

Dr. Edwin Pynchon, Chicago—Owing to the time limit I did not attempt to describe the operation in my paper or touch on the technic thereof. I have, however, brought with me the instruments I use, which it may interest you to see. In the

cautery handle I have the contact arranged on the outside so that it may be readily kept clean. I have had the ends of the electrodes made large so that the electrode is held more firmly in the handle. Platinum is not so good, I have found, as iridoplatinum, which you may heat red hot and it will still retain its shape. These electrodes and the handle are made by F. A. Birtman & Co. of Chicago. I have here also a tongue depressor which enables the patient to hold down his own tongue. And here are some forceps I find very convenient for grasping the tonsil. Several of the objections made by the gentlemen were already met in the paper which they did not hear, as they came in too late. Dr. Myles, this morning, mentioned the inefficiency of the tonsillotome in removing the tonsils. If any of you desire to become familiar with this operation, I will take great pleasure in sending you a description thereof in a reprint. It was not the purpose of the paper to deal with the enlarged tonsil, which is of annoyance chiefly as an obstruction. Its follicles are very small, and it is simply an obstruction, and that is all. Follicular hypertrophy is found in the degenerated condition of which my paper treats. As to Coulter and myself, I reported the operation in 1890, and Dr. Coulter, I believe, began doing the operation about five years later and has become quite enthusiastic over his results. He has done good work. One of the physicians thought it was a septic inflammation which follows the removal of the tonsil in this way; it is not a septic condition, but a burn; an eschar made to keep out sepsis. After the operation I apply a 20 per cent. solution of nitrate of silver and thus make a coating over the wound. I originally took out the entire tonsil at one sitting and sometimes had hemorrhage therefrom. Now, since dividing the operation in two steps, I do not have much hemorrhage. Anybody who does radical work on the tonsil will have an occasional hemorrhage. The hemorrhage I got was chiefly a capillary hemorrhage. There was no point of spurting. I found the motion of the tongue assisted somewhat in the production of hemorrhage, so I took out one half of the tonsil at a time. The greatest amount of expertness is required in removing the upper half. There is hardly any hemorrhage from removing the lower half, nor is there much pain. Nowadays, when I see a little bleeding point, I cauterize that point and apply nitrate of silver. In this manner I can do a practically bloodless operation. Most of the bleeding is where the forceps take hold of the tonsil, to pull it out of its bed, but this amounts to only a few drops. The after-effect of the cocain may cause some secondary hemorrhage, but now I generally avoid that. The time required for the operation depends largely on the dexterity of the operator. I have taken out an entire tonsil in two and a half minutes. I have frequently taken out the upper half in from one and a half to two minutes. I usually work for half a minute and then rest a minute, and then work again for half a minute. In these cases the follicular element is hypertrophied. Dr. Kuyk mentioned something entirely apropos, and that is the matter of cicatricial contraction. I have once in a while had slight cicatricial contraction. I have found if before I operate the anterior pillar is adherent to the tongue that it becomes reattached later on. If the anterior pillar is not attached at the start it does not become attached after the operation. If you make the incision longitudinally in the muscle you will not get contration; but if you make the incision across the muscle, you may get contraction. In regard to the cases sent to Dr. Ballenger for inspection they were not picked cases. I sent him several cases operated on from three or four to as long as ten years ago. In regard to the use of the angular knife of Yearsley I do not think that the tonsil can be entirely removed with the knife, because bleeding obscures the field so one can not get all the follicular element in that way. I learned that the submerged tonsil was very much buried beneath the anterior pillar so after its removal there was left a hole which would retain secretions, therefore I began to take away more and more of the pillar. You see, gentlemen, this operation is the outgrowth of experience and trial. What I take away is principally mucous membrane of the pillar. After the wound is healed one can not see that any of the anterior pillar has been sacrificed. The part of the pillar I remove is the posterior edge of the anterior pillar. As to cocain, I have never had a prostration from the application of cocain to the fauces when applied with the cotton applicator. I always add from 5 to 10 per cent. of phenol to my cocain solution, and that may have something to do with it. I formerly used stronger solutions of cocain, but now I frequently get good results from a 10 per cent. solution. I have sometimes used hypodermatic injections of cocain in the pillars. It does not do any good to inject cocain into the tonsil, but it must be injected into the pillars, and preferably under the mucous membrane, so as to produce a bleb, but I have had some intoxication from so doing. By making applications of a 10 per cent. solution and taking plenty of time, I generally get good anesthesia, and I have fancied that the tendency to hemorrhage has been less than when stronger solutions were used. As to the line of demarcation, you will at first find a general redness of the fauces, but if you make the patient gag it will lighten up the anterior part and darken the posterior part, so the line of demarcation shows up clear and distinct, it being directly over the anterior edge of the diseased tonsil. In practice I find the burn causes no harm to the pillar at all, and I make the incision while the patient is on the gag. I remove all of the diseased tissue, and with the after-treatment the wound heals up properly. During the time of healing I insist on the patient returning regularly so I can massage the wound. There is a tendency for connective tissue to form in the wound so it fills up irregularly, therefore I massage it so as to make it heal up solid from the bottom. I fully agree with Dr. Gibbons as to the desirability of getting rid of a diseased tonsil. The total loss of a tonsil does the economy no harm. It is bad surgery to partially remove a diseased tonsil.

DR. BARNHILL—If you could dissect the tonsil loose and remove it as completely with the snare, would you still prefer your method?

DR. PYNCHON—I want to do the operation in a bloodless manner, if possible, and I can do that better with the hot point. After dissecting the tonsil loose so that it is ready to come out, which would be the better to do: to put on the snare or to simply complete the removal with the hot point? What is the use of changing then to the snare? In a very sensitive patient or a child I may use a tonsillotome to clip off the partially loosened piece, but that is the only time.

OTITIC BRAIN ABSCESS.

REPORT OF TWO CASES: APHASIA IN ONE, RECOVERY.*

GEORGE F. KEIPER, A.M., M.D.

Eye and Ear Surgeon to St. Elizabeth Hospital, St. Joseph Orphan Asylum, Indiana State Soldiers' Home, Children's Home; Lecturer on Eye, Ear, Nose and Throat to Training Schools for Nurses at St. Elizabeth Hospital and Indiana State Soldiers' Home.

LAFAYETTE, IND.

CASE 1.—May 7, 1900, through the kindness of Dr. A. B. Westfall, I was called to see John S., aged 18, who had been taken to St. Elizabeth Hospital. He had suffered with the left side of his head for a month. His condition was as follows: His temperature was 102; pulse, 124; extreme prostration was manifest and his general appearance indicated extreme pyemia. The left ear was discharging. The mastoid was tender to the touch. His tongue was covered with a brown fur and his teeth with sordes. The patient was perfectly rational and answered questions intelligently; no examination was made for aphasia because of the patient's extreme condition. Because of this an immediate operation was agreed on.

At 11 a. m., with the assistance of Drs. Westfall, Throckmorton, White, Morrison, Lee, Hillis and Hopper, the operation was begun in the usual way. The periosteum was scraped aside. When the trephine was applied over the site of the mastoid antrum and given two turns it suddenly sank into the bone. Removing it with the button of bone we saw the whole bone necrosed and filled with granulations and with the most

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. Emil Mayer, C. R. Holmes and G. H. Makuen.

offensive pus of a greenish hue. The bone was so rotten that all debris was removed by a sharp spoon only. The tegmen between antrum and brain cavity was also necrosed. This was removed and the dura opened. After cleansing the cavity in dura and bone the wound was packed, drained and dressed.

May 7.

At 1:30 p. m. the temperature dropped to 98, and pulse to 94.
At 3:30 p. m. it was 101.4 F., and pulse 92.

At 5:00 p. m., 101.2 F., P. 96. At 9:30 p. m., 103.6 F., P. 120.
At 6:30 p. m., 103.4 F., P. 105. At 11:00 p. m., 104 F., P. 106.
At 8:30 p. m., 104 F., P. 124.

May 8.

At 1:45 a. m., 102 F., P. 104. At 10:50 a. m., 103.6 F., P. 130.
At 5:00 a. m., 102 F., P. 106. At 12:15 p. m., 103 F., P. 94.
At 7:00 a. m., 103.2 F., P. 102. At 2:00 p. m., 104 F., P. 100.
At 8:45 a. m., 103.8 F., P. 104. At 4:45 p. m., 103 F., P. 94.
At 9:45 a. m., 104.2 F., P. 130. At 7:25 p. m., 104.6 F., P. 104.

Because of the pulse and temperature it was felt that a further exploration of the brain cavity should be made. At 8:30 p. m., with the same physicians assisting, the wound was reopened and the skin incision was continued upward and the bone beneath skin and periosteum was removed by rongeur to the extent of a square inch. The dura was black and necrotic. This was opened after ascertaining that it was loose as far around as a probe could be passed between dura and bone. The temporosphenoidal lobe was necrotic. The pus was as offensive as ever. The lateral sinus and jugular were free. After cleansing the brain cavity as carefully as possible it was drained with gauze and the wound dressed. The patient was put to bed at 9:25 p. m., when the temperature was 102 and pulse 98.

May 9.

At 12:30 a. m., 102 F., P. 98. At 12:30 p. m., 102 F., P. 101.
At 3:10 a. m., 101 F., P. 98. At 3:30 p. m., 101.8 F., P. 100.
At 5:00 a. m., 100.6 F., P. 96. At 6:00 p. m., 103.6 F., P. 112.
At 7:45 a. m., 100.8 F., P. 94. At 9:30 p. m., 102.4 F., P. 110.
At 10:00 a. m., 104.4 F., P. 113. At 12:00 m., 102 F., P. 106.

May 10.

At 3:00 a. m., 102.4 F., P. 110. At 3:00 p. m., 99.2 F., P. 100.
At 5:30 a. m., 103.4 F., P. 112. At 7:00 p. m., 99.2 F., P. 100.
At 9:00 a. m., 102.6 F., P. 114. At 11:00 p. m., 98 F., P. 118.
At 12:00 m., 100.8 F., P. 114.

May 11.

At 2:00 a. m., 101 F., P. 124. At 1:45 p. m., 99.2 F., P. 124.
At 6:00 a. m., 101 F., P. 120. At 5:30 p. m., 101.6 F., P. 135.
At 8:00 a. m., 100.4 F., P. 116. At 9:00 p. m., 103 F., P. 125.
At 10:00 a. m., 100.8 F., P. 116.

May 12.

At 1:00 a. m., 104.6 F., P. 144. At 2:00 p. m., 102.6 F., P. 140.
At 5:00 a. m., 103.4 F., P. 140. At 5:35 p. m., 101.4 F., P. 140.
At 8:15 a. m., 103.6 F., P. 150. At 9:35 p. m. 102.8 F., P. 130.
At 11:00 a. m., 104.4 F., P. 140.

May 13.

At 1:00 a. m., 103.4 F., P. 132. At 12:00 m., 105 F., P. 150.
At 4:00 a. m., 103 F., P. 132. At 6:00 p. m., 104.4 F., P. 158.
At 6:00 a. m., 103 F., P. 132. At 10:35 p. m., 102 F., P. 145.

May 14.

At 1:30 a. m., 103.2 F., P. 145. At 1:30 p. m., 104.4 F., P. 158.
At 6:00 a. m., 103 F., P. 145. At 4:30 p. m., 103 F., P. 165.
At 9:00 a. m., 104.2 F., P. 144.

The patient died shortly after this. The respirations were hurried in proportion. Several injections of anti-streptococcic serum were of no avail. Nuclein was also tried with a similar result. The patient could not retain food either by mouth or rectum. Normal saline injections per rectum were rejected. Then they were tried subcutaneously. Wherever introduced the skin sloughed markedly. The odor was so frightful that in dressing the wound every three or four hours it was necessary to stop one's nostrils until we used equal parts of oil of eucalyptus and menthol in the wound, which was suggested by Dr. McMahon, who received it from Dr. Ida Levering of Secundrabad, India. This controlled the odor beautifully and removed the disagreeableness of dressing the wound so frequently.

The remarkable feature of this case was the fact that his mental faculties were unimpaired to the very last, notwithstanding the extensive destruction of brain tissue.

Case 2.—July 26, 1901, through the courtesy of Drs. Hillis and Thompson, I was asked to see F. M., aged 37, a traveling salesman, who had a running ear, which had troubled him for a month, together with a tenderness over the mastoid. Before coming to Drs. Hillis and Thompson an icebag had been applied continuously in the hope of curing the trouble. The left ear was discharging profusely, but the mastoid was not tender, except slightly over the supposed seat of the antrum. The patient's general condition was poor. He suffered much frontal headache, chilliness with flashes of heat and mental hebetude. The temperature as in intermittent fever. The pulse was slow. The ear was immediately cleansed, dryed and filled with dry boric acid powder. A Japanese pocket stove was applied over the mastoid. The general treatment consisted of calomel purge and quinin sulphate grs. 3 every three hours. He was impressed with the gravity of his condition. July 27 found him no better. July 28 the symptoms of mastoiditis were still present, with marked headache, mental dulness, vomiting and rigors.

Operation on the mastoid was proposed and the patient accepted the advice. All the usual preparations were made, and with the assistance of Drs. Hillis, Beasley, Throckmorton and Bartholomew the mastoid process was opened in the usual way. However, we found the antrum located one-half inch above the place where we usually expect to find it. It was filled with pus and cholesteatomatous masses, and the detritus of dead bone. The tegmen was eroded. The bone was thoroughly cleaned out. Then the brain cavity was explored, but no evidences of pus were found. It may be that at the time the abscess was small or the needle of the aspirator did not penetrate it or the needle may have gone clear through it. However, no further efforts were made to find the abscess. The wound was dressed and the patient put to bed at 10:40 a. m.

He did fairly well until August 15. However, in the meantime he still complained of headache. Kenyon's neuralgic tablets gave only a partial relief. In the afternoon of the above date he lapsed mentally, and when I reached his bedside he could only say: "I hope I'll be better, doctor." He thus continued until evening, when he lapsed into unconsciousness. In this condition he was taken to the operating room at 9:40 p. m.

The wound was reopened, and with the assistance of Drs. Thompson, Davidson, Throckmorton and Bartholomew, the wound in the bone was enlarged by the removal of a square inch over the temporosphenoidal lobe. The dura bulged. Inserting a small trocar and attaching the aspirator, we were rewarded by finding pus. This was evacuated to the extent of two ounces. The dura was opened, the cavity cleaned and dried and a drainage tube inserted. The wound was then closed and dressed.

At 11:30 he was put to bed, and at 12:30 a. m. he awoke partially conscious. At 3 a. m. he asked for a drink and was rational at times. When visited in the morning he was partially rational, but his memory for a great many things was gone. He could not remember my name, and could not call the names of close friends or things about the room. He realized his deficiency, and remarked that it was strange that he could not recall the name of things which he saw. Still the burden of his conversation was that he hoped to be better soon. His temperature was normal and his pulse was 74. He complained of no pain in his head. By the 17th he was able to write my name, though he could not call it.

On the 18th his pulse slowed down to 64, with a temperature of 101.6 F. at 11:15 p. m. It continued thus on the 19th. He was dull mentally. At 8 p. m. we concluded to put him on the table again. Examination of the wound showed drainage to be somewhat indirect. The wound was reopened and some more bone removed posteriorly. Then the drainage tube drained directly outward. He was returned to his room at 9:40, with a temperature of 98 F. and a pulse of 80. Since then his recovery has been gradual, but perfect.

The patient manifested marked aphasia. In making up the description of his case I will follow the plan of Bastian, as given in the report of a case similar to mine by Drs. Jack and Walton[1] of Boston.

A.—Preliminary qualifications.

1. Patient is right-handed.
2. No paralysis of face or limbs.
3. He is a traveling salesman, well informed.

1. Boston Med. and Surg. Jour., Dec. 26, 1901.

B.—Activity of auditory word center and glossokinesthetic center, with afferent commissural and emissive fibers.

4. Patient deaf on left side only.
5. Recognizes and appreciates ordinary sounds and noises.
6. Comprehends simple speech; obeys orders, but does not know names of objects previously familiar.
7. Spontaneous speech impaired. Uses word "business" when he can not remember real name of object.
8. Can not name days of week and months of year without coaching.
9. Can repeat short sentences uttered to him fairly well only.
10. Has no musical ability.
11. Has no musical ability to carry a tune.

C.—Activity of visual word center and cheirokinesthetic center with their afferent commissural and emissive fibers.

12. Sight good.
13. Recognizes simple printed words.
14. Recognizes individual letters and numerals.
15 and 16. He can read his own writing after making it.
17. Recognizes common objects but can not call their names. Calls all alike "business."
18. Does not recognize gestures.
19. Writes only fairly well.

Symptoms.	Mastoiditis.	Brain Abscess.	Lepto- and Pachy-meningitis.	Sinus Thrombosis.
Pain in ear	Mark'd with swelling of posterior-superior wall of auditory canal.	Usually severe		
Pain in head	Mastoid tender to pressure and percussion.	Often frontal and very severe	Rarely absent; early and severe	Tenderness over mastoid and sigmoid sinus.
Temperature	Normal or but slightly elevat'd	Rarely elevated except in extremis	Elevated; flushing of face	Very high; fluctuating markedly.
Pulse	Normal	Slow	Rapid	Rapid; fluctuating.
Respiration	"	"	Cheyne-Stokes	" "
Vomiting	None	Often present in first stages	Rarely absent	In early stages.
Digestive system	Constipated; tongue may be coated.	Constipation; tongue coated; breath offensive.	Great thirst; loss of appetite; abdomen retracted.	Diarrhea; severe abdominal pain; tongue dry and coated; may simulate typhoid.
Mentality	Normal	Cerebration may be slow	Delirium; irritability; extreme restlessness.	Normal.
Drowsiness	None	After week of pain		None.
Shivering	"	Usual	Generally present, but not so marked as in sinus thrombosis.	Rigors are very frequent.
Giddiness	"	Often, especially in cerebellar abscess.	In early stages	Sometimes observed.
Local rigidities	"	None; retraction of head in cerebellar abscess.	Often observed; retraction of head	Convulsions may be local or general
Aphasia	"	Sometimes present	None	Not observed.
Coma	"	In last stages	In last stages	In last stages.
Ocular apparatus.	Normal	Photophobia; pupils contracted; optic neuritis; blindness with dilated pupils in cerebellar abscess.	Pupils sluggish; optic neuritis	
Discharge from ear.	Usually purulent	Often present		Often present.
Emaciation	None	Marked; rapid and progressive	None	May be present.
Pulmonary symptoms.	"	None	"	Often present; due to infarcts; prune-juice expectoration; jugular vein may be involved.

20. Can write his own name, the name of his physician (though he can not call it aloud). Knows location of a physician's office, but can not call his name, though acquainted with him.
21. Copies well, though he uses word "are" for "or."
22 and 23. Copies numerals and can make calculations.
24, 25 and 26. No tests in reading and writing music.

D.—The associated activity of three centers with commissures between auditory and visual word centers or other sets of afferent and emissive fibers.

28. Reads perfectly simple words, but not difficult ones.
29. Can name at sight letters and numerals.
30. Can not name at sight many common things, such as his victuals.
31. Can point to common objects whose name he hears.
32. In writing "A, B, C" he makes "1, 1, 1."
33. As above.
34. Can not play musical instruments.

The patient has made a good recovery. The last defect in writing to disappear was the substitution of the word "are" for "or."

VARIETIES OF APHASIA.

This brings us to a brief study of aphasia. As Dana well says: "Aphasia is a disorder of the faculty of language; and it has a number of varieties, in accordance with the particular part of the brain involved and the particular portion of the mechanism of this faculty that is destroyed." Memory, of course, is involved in this process. Nordau in his work on "Degeneration" has beautifully given us the idea that memory is nothing but stored up nerve-cell action. The forms of aphasia are:

1. Word blindness (alexia). The patient can see and spell the letters of a word but can not read.

2. Sign blindness (apraxia), when the subject can not understand the meaning of signs as he once did.

3. Both of these combined make mind blindness, because the patient can not understand what he sees.

4. Word deafness. What the patient hears is, as it were, in a foreign language.

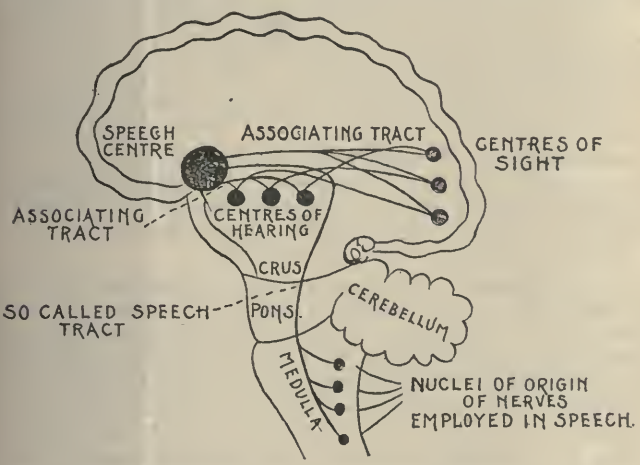
5. Motor aphasia, which is manifested under aphemia, i. e., where the patient knows what he sees but can not express by the organs of articulation what he sees. Our patient had to learn again after a painful process to pronounce the names of common objects around him. Motor aphasia is also manifested under agraphia, i. e., where the patient can not use his muscular apparatus in writing what he sees, though again he knows the names of what he sees.

6. Conduction aphasia. The patient can write or speak but is confused in his expression.

7. Then the patient may manifest a combination of the above, and this is called mixed aphasia.

The parts involved in aphasia are:

1. Conductive aphasia—island of Reil.
2. True motor aphasia—Broca's convolution.
4. Word deafness—first temporal convolution of left side.
5. Word blindness—occipital lobes.



ETIOLOGY.

Consideration of the etiology of brain abscess involves consideration of the anatomy of the temporal bone in its relation to the middle cranial fossa and to the lateral sinus. The plate of bone between the mastoid antrum and cranial fossa is very thin, quite translucent in fact. The plate between the sigmoid sinus and antrum is but a little thicker. Neither is as thick as the external plate of bone. Pus traveling in the direction of

the least resistance, when the aditus ad antrum is closed, or partially so, must involve the brain tissue or lateral sinus before it can erode through the external wall of the antrum, though in several instances the writer has found sinuses from the outside leading into the bone at or near the foramen for the emissary mastoid vein. The tegmen may be in a living state and yet the blood vessels running through it may spread infection to the brain itself. In the involvement of the lateral sinus the purulent matter may erode the bone and infect the sinus thus; the slowness of the blood current in the sinus facilitating the process. When the sinus becomes thrombosed in its whole extent the infection naturally spreads to cerebellum.

PROGNOSIS.

Before the appearance of that classic of MacEwen on "Pyogenic Diseases of the Brain and Spinal Cord" but little was attempted except in a medical way. Patients usually died. MacEwen's experience with cerebral abscess shows that of nineteen cases operated on, eighteen recovered. In thrombosis of the sigmoid sinus of seventeen cases operated on, thirteen recovered and four died. In extradural abscess he lost none of the five cases on which he operated. In the report of seventy-four operations he had deaths only in the following: five from pyogenic cerebrospinal leptomeningitis, one from abscess of the frontal lobe, one from meningo-encephalitis of the frontal lobe, one from total necrosis of the temporosphenoidal lobe and four from thrombosis of the sigmoid sinus, making only twelve deaths in a disease hitherto regarded fatal. If the surgeon can get the case before the process has extended to the adjacent structures of the mastoid antrum, the operation of opening and cleaning out the mastoid is almost universally successful.

In my own experience it has been my good fortune to have saved all my uncomplicated mastoid cases. In addition to the death above described, the writer has had only three others: two in which the lateral sinus was badly involved and one where the patient died five weeks after the operation with what the consultants and myself agreed to be tubercular meningitis. The patient was a negro with tubercular tendencies.

SYMPTOMS.

The table herewith subjoined gives at a glance comparatively the symptoms of mastoiditis, brain abscess, lepto- and pachy-meningitis and sinus thrombosis. It also gives at a glance the differential diagnosis between the different diseases.

TREATMENT.

This is resolved into preventive and operative treatment.

Preventative treatment consists in treating carefully every case of otitis media which comes under observation. It is for our encouragement that acute purulent otitis media seldom causes mastoiditis. The primary cause of mastoiditis and brain abscess in almost every instance is chronic purulent otitis media, which the patient is too often left to outgrow. This form is dangerous, and, as MacEwen says, "one may just as well go around with a charge of dynamite in his head as with a chronic purulent otitis media."

Operative treatment consists first, in opening and cleaning out the mastoid, and, second, in opening and cleaning out diseased foci in brain and lateral sinus. Dench, in a recent article in The Journal of the American Medical Association, takes the ground that in a case of doubt an exploratory operation is justifiable. He probably has had the largest experience of any operator in the country. If the tegmen is involved it should be removed, and if the pulse has been slow, with pain in the head and vomiting, a large aspirator needle should be introduced into the brain in various directions. If pus is present the wound is to be enlarged with a bistoury, which may be sufficient, as in a recent case reported by Jack of Boston.

If the lateral sinus be involved, and the symptoms will usually tell, this must be opened and cleaned out, and if the internal jugular be involved, too, it should be ligated.

The after-treatment consists in keeping the patient quiet and on a milk diet. He should stay in bed from four to six weeks and not rise until the brain wound is healed.

Concerning the renewal of dressings, they should not be disturbed oftener than necessary.

THE CHOICE OF A GENERAL ANESTHETIC IN NOSE, THROAT AND EAR OPERATIONS.*

THOS. J. GALLAHER, A.M., M.D.
LARYNGOLOGIST, ST. LUKE'S HOSPITAL.
DENVER.

The choice of a general anesthetic in nose, throat and ear operative cases will depend on the general condition of the patient, the age and the extent of the surgical work required. The anesthetics employed in this line of work are: chloroform, alone or with oxygen, ether, nitrous oxid, alone or combined with oxygen, and ethyl bromid. The systemic conditions which must be considered in using these anesthetics are the same as in other surgical procedures, viz., the condition of the heart, the kidneys, the blood vessels and, locally, conditions in the upper respiratory tract, stenosis of larynx and pulmonary tuberculosis.

In all cases requiring a prolonged narcosis, such as in mastoid operations, operations on the middle ear, certain operations in the nose and nasopharynx, ether is certainly safer and is to be preferred, unless it produces too much irritation in the upper respiratory tract. My experience with chloroform among children has been very satisfactory, they taking the anesthetic easily and quickly. I have found it rarely necessary to employ ether among children. The use of nitrous oxid in children from 3 to 10 years of age, is attended with considerable difficulty, owing to the impossibility of holding the child still and preventing the admixture of air with the gas. It requires from one to two minutes to produce complete anesthesia, which lasts about one minute; when this gas can be administered to the child or adult in cases not requiring

* Read before the Denver and Arapahoe County Medical Society.

over a minute of anesthesia, this anesthetic is most excellent. It may be combined with oxygen to insure greater safety. I frequently use nitrous oxid in operating on the tonsils, incising the ear drum and in perforating the antrum through the nose, the canine fossa or through the alveolus.

The most convenient—and apparently as safe as any of the other anesthetics—is bromid of ethyl. This anesthetic should not be used in prolonged administration; it produces anesthesia in about one minute, lasting from two to five minutes, the patient awakening and almost at once regaining his normal condition. The amount required is from 3i to 3iv, according to age. A proper amount being measured, the whole quantity is thrown on a towel, lint or gauze, or in an inhaler, and placed over the patient's nose and mouth, and only in case of necessity or danger of asphyxiation should air be admitted. When the breathing becomes stertorous, usually about one minute, anesthesia becomes complete. It does not produce spasm of the glottis, resembling chloroform. In adults it requires a larger dose and more time to produce anesthesia. A temporary vasomotor dilatation occurs with this anesthetic, possibly producing more hemorrhage for a few seconds only, but as the effect of the drug is so short, slight hemorrhage is no contraindication to its use.

Vomiting frequently follows the use of bromid of ethyl, and it should be administered when the stomach is empty. In conclusion, bromid of ethyl must be regarded as a safe anesthetic; the German Surgical Congress, 1897, reports one death in 5,228 narcoses. From the confusing of bromid of ethyl with bromid of ethylene three fatalities are recorded. Bromid of ethylene is highly poisonous and resembles bromid of ethyl very much. Deaths have been reported from the use of impure bromid of ethyl and from asphyxia, syncope and prolonged administration.

The following excellent points are given by A. Brown Kelly,[1] surgeon Victoria Infirmary, Glasgow:

Precautions:

1. Use of pure bromid of ethyl.
2. Attention to patient's respiration.
3. Never prolong narcosis by repeating dose more than two or three times.

Advantages:

No special apparatus required.
Narcosis rapidly produced.
No irritation to respiratory mucous membrane.
Upright position of patient permissible.
Rapid regaining of consciousness.
Invaluable in dispensary work.

In regard to the position of the anesthetized patient, my rule is invariably to operate, placing them on the back, lowering the head so that the level of the pharynx is below the level of the larynx, unless from the nature of the case it is impossible to place them in this position. This position is preferred in our work because there is less danger of blood or severed growths entering the larynx, and it is a safeguard against syncope. Where it is necessary to have the patient in the upright position, or modified upright position, bromid of ethyl is to be preferred as the anesthetic; second choice is given to nitrous oxid, according to the length of anesthesia required.

The advantages of the bromid of ethyl are not generally appreciated by the profession. There are many minor surgical cases which can be operated on by the general surgeon with great satisfaction to himself and little inconvenience to the patient.

1. British Med. Jour., August, 1902.

More "Embalmed" Meat.—A short time ago an Owosso pharmacist ordered 25 pounds of saltpeter from his jobber in Detroit, and received it immediately by fast freight. It was sold to farmers of the neighborhood, who used it in curing meat. Recently so many complaints came in of the aperient properties of the meat that the wholesaler was asked to look into the matter, and it was found that a careless packer had sent epsom salts.—*Pharmaceutical Era.*

THE GIANT MAGNET IN OPHTHALMIC SURGERY.

REPORT OF TWO CASES—REMARKS.*

LEARTUS CONNOR, A.B., M.D.
DETROIT.

The extraction of foreign bodies from the interior of the eyeball presents an infinite variety of problems. These bodies are magnetic or non-magnetic—in this age of steel the magnetic are the rule. Before the use of the magnet extraction was by hooks or forceps and but few eyes were saved, especially if the foreign body was in the vitreous chamber.

The advent of the small magnet rendered extraction of magnetic splinters from the anterior chamber both easier and safer and some pieces were extracted from the vitreous without loss of the eye. The use of magnets or electromagnets as large as possible, introduced by Haab, marked a distinct advance, making it possible to save still more eyes. The usefulness of both small and large magnets has been enlarged by the localizing power of the *x*-ray and sideroscope.

Haab's paper, read before the Ophthalmic Section of the American Medical Association last June, just ten years after his first publication on the subject, awoke renewed interest in the subject, and showed that his followers in America were both numerous and enthusiastic.

I here report two illustrative cases:

CASE 1.—July 2, 1892, I. D., a vigorous blacksmith, aged 45, applied for treatment of an injury to his right eye received one hour before. This occurred while holding a piece of metal on an anvil, as a fellow workman, with blows from a heavy hammer, molded it into the required shape. He was conscious that something had hit his right eye, stunning him for a moment, and that he could not see as before.

Examination showed vision reduced to the counting of fingers by hemorrhage into the vitreous; the anterior chamber full and clear; a horizontal wound in the cornea extending from the right sclerocorneal junction, one-third the distance to the left. Directly behind was a similar wound in the iris, through which a bit of red reflex could be seen with the ophthalmoscope. The visual field was obscured by a cloudy vitreous so that nothing could be determined in this way as to the location of the steel splinter; nor could any damage to the lens be observed. Looking at these facts in the light of the rule in these cases, it was believed that the splinter had entered the eyeball, through cornea, iris, suspensory ligament and vitreous, thence dropping to the floor of the eyeball. A small magnet of considerable power applied through the route of entrance, gave no indication of the location of the splinter. Regarding the case as suitable for the giant magnet, I availed myself of the courtesy of Dr. Frothingham to use his instrument at Harper Hospital. His aid and that of Dr. Ray Connor at the operation contributed much to its favorable result.

Having anesthetized the cornea with cocain, and placed the patient and magnet so that the point of the latter could be easily approached to the center of the cornea, the instrument was placed in contact with the corneal wound, and the current very slowly turned on till its full power was secured. The result was negative, either as to pain or the appearance of the splinter, though the magnet was kept in contact with the eye for a considerable period.

After a few moments with the full current, the eye was slowly brought toward the point of the instrument, when suddenly a bulging was seen at the lowest part of the iris; a continuance of the current was followed by the rise of the splinter between the lens and iris to near the point of entrance. Here its jagged edges caught in the iris, and though the current was changed in many directions, it failed to effect a disentanglement. A small strabismus hook was introduced through the

* Read before the Detroit Ophthalmic Club.

wound so as to touch the splinter and connected with the magnet, but failed to dislodge it. A large hook was substituted, made to touch the splinter, its point being so directed as to draw the splinter inward and backward. Connecting this with the magnet, and slowly turning on the current, the splinter was seen to attach itself to the point of the hook, leave the iris, and so was readily drawn through the wounds. The splinter measured 3x2x½mm., with very sharp prongs on the end, caught in the iris.

Thus the giant magnet located the splinter on the floor of the vitreous chamber, drew it to the lens, around its lower edge, through the suspensory ligament, up the posterior chamber between the posterior surface of the iris and anterior surface of the lens to near the point of entrance, where it became entangled in the iris. Its release and final delivery through the original point of entrance was effected by the aid of a strabismus hook in properly directing the force of the current.

In all this there was practically no pain or hemorrhage into the anterior chamber.

The after-treatment was atropin, surgical asepsis, hot water applied locally to the eye, and rest. The bruised quadrant of the iris did not dilate for many days, though finally the pupil became nearly round, and the iris normally mobile.

July 4, there was slight circumcorneal injection, a yellowish-white color of the wound, clear lens, dark vitreous chamber; the fingers are easily counted.

The after course of the case was uneventful; no evidence of infection presented, and on July 28 he returned to work. At that time his vision was 8/200; lens still clear; upper and inner part of the fundus showed a red reflex, but the portion of the vitreous chamber through which the splinter traveled still remained opaque though retinal separation was not apparent.

The final result has not been reached, as on September 2 vision was 12/200, and lens clear.

October 7, vision is 12/200, lens with some striated lines, opaque spot in outer part, choroid at place of entrance of splinter.

The operation saved the eyeball in perfectly normal appearance with some sight. The size, location and patency of the wounds made it possible to extract the splinter without making fresh ones and rendered unnecessary the drawing of the splinter over the lens to the pupil in order to pass from the posterior to the anterior chamber, so reducing the peril to capsule and iris.

While exact locating of the splinter by *x*-ray and sideroscope would have rendered the diagnosis more certain, it is not clear that it would have conduced to a better result. The giant magnet both confirmed the diagnosis of a foreign body in the vitreous chamber and located it on the floor of the same—more could not be desired. It is not denied that it might have been extracted by a small magnet, had it been located by the *x*-ray, through an opening of the sclerotic, but the damage to the choroid and retina, with increased risk of infection, would have further imperiled the eye.

After the splinter appeared behind the iris it might have been extracted by the small magnet through a new opening of the cornea and iris. This also would have added to existing traumatism of the eye without practical advantage. Clearly from start to finish the giant magnet was the instrument most favorable to the securing of best results.

Case 2.—A. S., a healthy boy, aged 18; an apprentice in a machine shop, was referred to me on September 27 by Dr. Charles Stockwell of Port Huron. While working, a piece of metal from a hammer hit his right eye, causing a severe shock and instant loss of sight. As the accident occurred but a few hours previous to his visit to me, the wound was fresh.

Examination showed anterior chamber clear; the cornea cut horizontally more than half across, beginning at outer sclero-corneal junction and ending in an upward curve to near the superior corneal margin; the iris was fully divided beneath; the lens smashed so that it was impossible to see through it, and the patient could only distinguish light from darkness.

Time being limited, he was at once taken to Harper Hospital and operated on by the giant magnet, kindly loaned by Dr. Frothingham, assisted by Dr. Guy L. Connor and the house staff.

The point of the magnet was placed in contact with the inner end of the corneal wound, and the current turned on slowly. After some moments the patient complained of pain; the iris and lens mass at inferior portion of anterior chamber were seen to bulge forward and upward. The splinter had engaged sidewise rather than endwise and was held from advancing by the lens capsule. A change in the direction of the magnetic force freed the splinter, when it flew to the point of the magnet. Meantime the anterior chamber had filled with blood from the damage done by the splinter. The edges of the wound were cleaned, atropin dropped into the conjunctival cul-de-sac, the eye bandaged and the patient returned to his home.

The route of the splinter was clearly through cornea, iris and lens, dropping to floor of vitreous chamber. Thence the magnetic force drew it forward to the lens debris, then upward and outward through openings of iris and cornea. Clearly the giant magnet confirmed the diagnosis and extracted the splinter with least additional injury to the eye.

The splinter measured 6x3x1 mm., thus explaining the extensive traumatism.

October 6, Dr. Stockwell reported the patient was doing well; had suffered no pain, except on the evening of the 2d, which was easily controlled by the local use of atropin, and an anodyne; the rent in the cornea and iris closed; opaque lens showing in the inner portion of the pupil; tenderness of eyeball, and congestion of conjunctiva disappearing. As nine days have passed since the injury, it may be assumed that danger of infection has vanished, and that we have to deal with the traumatism of the lens and vitreous chamber. The first will either disappear by absorption, or can be removed by operation—the second is still an unknown quantity. It is quite certain that the eye will be retained, and look practically as well as the uninjured eye; it is possible that useful vision may be secured.

From a careful study of these cases the writer is convinced that, without the giant magnet, enucleation would have been imperative in both. With the giant magnet a safe eye is retained in each case, some vision in the first and possibly in the second—a distinct gain over former resources.

The great cost of Haab's magnet has restricted its use, but cheaper substitutes by different operators have multiplied, which, if not equally good, are far better than the small magnets. With an increased demand because of lessened cost, it will not be long ere they will be in the hands of most doing much eye work. With such multiplication will come enlarged experience and greater skill, so that finally they may take the place of the small magnet in all cases that can be brought to hospital or office. Haab says that one magnet suffices for all his cases, and that it is as rational to have a large and small hole for a cat and her kittens as two magnets for different cases.

The technic of extraction of splinters from the vitreous chamber is far from being as simple as might appear. The most experienced are still learning, and beginners do well to heed their suggestions. The great power of the giant magnet renders it capable of irreparable harm if wrongly directed, or infinite good if rightly.

The experimental work, added to the clinical evidence of numerous observers, combines to show that at contact and up to two mm. the power of the small magnet equals, if not surpasses, the giant, but from this distance to 10 mm. the power of the giant increases in almost geometric ratio. From this fact it

is clear that the small magnet is suited only to such cases as admit of its point being brought in direct contact with the splinter, while the remaining cases are clearly within the domain of the giant magnet. Under this view of the case most, if not all, splinters in the vitreous should be extracted with the giant magnet, and not a few in the aqueous chamber.

Experiment and observation show that the farther the magnet is from the splinter the more uniform the action of its force, and the nearer the more jerky such force—the stronger the magnet the more marked this law. It follows that in practice it is wise to either (1) bring the eye close to the magnet point ere starting the current and increase its power very slowly, or (2) bring the eye from a considerable distance toward the point of the magnet with full current very gradually. The jerky force is liable to draw the splinter into the ciliary body, whence it is removed with difficulty, if at all, or it may draw it into some other undesirable location. To rectify this state of the splinter Dr. Kipp has shown us how to utilize the other tip of the magnet to repel the splinter from its misadventure; of course, this calls for a double-ended magnet. In his case the splinter fixed itself firmly in the ciliary body, and no change in direction of the magnetic force would dislodge it. He reversed the pole, when the splinter was released and readily removed. Possibly had this fact been known many failures would have been avoided, as even Haab reports failure from this cause.

When the splinter is caught in the iris one method of its release is given in the first case. Another is the use of the repelling power of the opposite pole. Still another is given by Haab thus: make an opening in the cornea directly over the site of the splinter, then enter with an iris forceps and grasp the iris just beyond the inner edge of the splinter, and gently push it inward till a rent is made in the iris over the splinter. The magnet is now applied at the artificial opening and the fragment extracted. The tear soon heals and the iris regains its normal motility—a far preferable plan to an iridectomy.

Haab so places his magnet that the force shall pass directly through the center of the cornea, expecting the splinter to approach the posterior pole of the lens, curve around its posterior surface, penetrate the suspensory ligament, enter the aqueous chamber, pass between the posterior surface of the iris and anterior surface of lens to the pupillary opening, whence it is extracted by a conveniently located corneal incision. In cases like those reported, where the wound in the cornea is large and freshly made, a new corneal incision is superfluous and the placing of the magnetic current over the fresh wound more desirable. Doubtless other cases will make it desirable to depart from Haab's rule.

A comparison of Haab's results with the small magnet and those with the giant are suggestive. The former are given by Adolph Hurzler, in Morris and Oliver's System of Ophthalmology. Of 18 cases operated on before 1892 by the small magnet, the foreign body was in the vitreous chamber; the splinter was not found in 5 cases; was extracted in 13; vision of 1/7 was secured in one case; the counting of fingers in 8; most had detachment of the retina; and in 7 the eyes had to be sacrificed. In commenting on this Knapp says that his experience was not quite so bad, as he had obtained perfect sight in a few cases where the foreign body could be seen and extracted soon after entrance.

Since 1892 to June, 1902, Haab reports 165 operations with the giant magnet. Of these 23 failed; 39 eyes were enucleated; 9 had lingering cyclitis; 19 were saved from inflammation, but were sightless. Of 71 cataracts extracted 51 had good vision.

His failure to extract the foreign body he lays to four causes: 1, A firm fixation of the splinter in the posterior wall of the eyeball (emphasis to be placed on the "firm," as in other cases the splinter was extracted from the same location); 2, firm fixation of the splinter in the ciliary body; 3, splinter held by a fibrinous exudate; 4, a splinter healed over in the lapse of months. These are some of the limitations of the giant magnet.

As elsewhere, infection by the penetration of a splinter is fatal to the eye and always a source of anxiety after the removal of the foreign body. Haab, to guard against this, introduces into the eyeball a specially prepared plug of iodoform, as both protective and curative. Most operators content themselves with placing the eye at rest with atropin and the general health in such condition as to best resist infection and promote repair of the damage done thereby.

Since the introduction of the giant magnet the *x*-ray and sideroscope have increased our power of localization, so making it possible to accomplish far more with the small magnet. They have also advantaged the use of the giant magnet; but it is clear that the latter enables us to do many successful extractions of foreign bodies from the vitreous chamber hitherto impossible.

103 Cass Street.

SOME NEW AND UNUSUAL THERAPEUTIC APPLICATIONS OF ERGOT.*

ALFRED T. LIVINGSTON, M.D.
JAMESTOWN, N. Y.

In Wood's Reference Handbook it is stated that ergot "appears to have been used by the peasantry in some parts of Europe in childbirth as much as three hundred years ago—but its formal introduction into modern medicine is due to the efforts of Dr. Stearns of New York in the early part of the present (nineteenth) century." I quote again from the same source: "The greatest value of ergot in therapeutics depends on its action on the uterus," and "Ergot is also to be recommended in all forms of capillary hemorrhages." This is essentially the ergot-therapy of the books, as well as of general practice to-day, but you will invariably find long dissertations on its poisonous effects, ergotism.

THE AUTHOR'S EARLY EXPERIENCE.

It is almost thirty years since, as assistant physician in the State Lunatic Asylum of Utica, N. Y., I began to use ergot to modify the hyperemia of the brain in insanity, especially in the melancholic class. We there used the drug almost wholly in the form of the fluid extract administered by the mouth, but I remember that I experimented, during my service there, with various preparations which I made to use hypodermically. I can not now recall the other uses to which I put the drug while at Utica; but there must have been others, for I distinctly recollect that one of the first preparations which I made for the practice of my profession in Philadelphia, to which city I removed in the autumn of 1878, was the making of a solution of the Bonjean ergotin for hypodermic use to carry in my pocket.

* Read before the New York County Med. Assn., March 16, 1903.

THE USE OF ERGOT IN CONGESTION OF THE HEAD.

It was thus that I was prepared to meet the demands of a very striking case, which I will relate, because it is from that hour I date my appreciation, which but gradually developed through many years, of the broad therapeutic application of ergot.

I had been in Philadelphia but a few weeks when an emergency call took me to a house on Sansom street, above Tenth, now, I believe, a part of the Jefferson College property. I found a very plethoric old man sitting in a large arm chair, retching violently. I had never before, nor have I since, seen such retching. It appeared that, after a usual supper, he had gone out on the street, but soon returned and began to vomit and from that time until I was called, at 11 o'clock, he had been continuously vomiting or retching. He was so completely exhausted that he did not lean forward or even hold up his head, which lay against the back of the chair. I did not attempt to question him, for he was too much occupied to reply, and, as his housekeeper could give me no further light on the case, I was obliged to draw my conclusions from what I saw; as I learned to do in dealing with the insane. The frontal vein was not a whit less in size than my little finger, and the general engorgement of head and neck I have never seen equaled. His pulse was rapid, full, bounding and hard. Between retchings he murmured but one word, "pain"! From the moment I first saw him I feared there would be a rupture of a blood vessel of the brain before I could relieve the terrible straining. I concluded that whatever the fundamental cause of this tremendous disturbance of the circulation, the present retching and pain were due to vascular engorgement within the head and that the immediate indication was to contract the dilated blood vessels. With this conclusion came the recollection of my ergot, which I began at once to administer hypodermically. I gave it slowly, as I had learned that it was not desirable to inject a syringeful of ergot as suddenly as a hypodermic of morphia is frequently given. As I progressed with the injection, I observed a gradual change in his symptoms, a lessening both of the vascular tension and of the retching. In acute disturbances of the circulation the rapidity of action of ergot is simply astounding. By the time I had emptied the syringe the suffusion had disappeared, the retching had ceased, the pulse was soft and but little accelerated, the patient was quiet and appeared comfortable. The cyclone which had been raging for four hours had passed and there was calm.

The excitement in the household had drawn many people into his room, and I detailed several of the men to undress him and put him in bed. Although there was then no indication for it, as a precaution against being called to him in the night, I gave him another hypodermic of the ergot and left him. The next morning I learned that a few minutes after I left him he fell asleep and slept continuously for six hours.

Two weeks later I was hurriedly called to him in the early morning, and found him in as great mental excitement as his previous physical excitement had been. He had just discovered that his escritoire had been pried open and a wallet containing nearly a thousand dollars had been stolen. He was practically in acute melancholia, wringing his hands, weeping and exclaiming: "Oh, God! oh, God!" in most pitiful fashion. I again applied my ergot as before, and, although it was not magical enough to restore the money, it did, as promptly as before, restore his calm.

EXPLANATION OF ITS SPECIFIC ACTION ON VASCULAR DILATATION.

I had now, within a fortnight, two impressive object lessons on the therapy of ergot, which have remained vivid through these twenty-five years. The first demonstrated that ergot contracts dilated blood vessels; the second demonstrated that ergot subdues an intense nervous excitement and causes it to disappear, although the cause of the excitement remains. My reflections on the latter and my observations of the action of ergot on many and varied disorders which are usually regarded and treated from the purely nervous standpoint, have led me to conclude that the primary disorder in the mass of nervous conditions is in the circulation in and about those nervous structures whose functional derangements are noted and that therefore the primary indication is not so much nerve foods, nerve tonics, nerve stimulants, nerve sedatives and rest, as it is an equable circulation, a circulation that is in tone in all its parts. The more I deal with nervous conditions the less use I have for phosphorus, nux or strychnia, iron, quinia, opium, the bromids or other depressant salts, and the more use I have for anything and everything that tends to equalize and tone the circulation; a proper activity of the bowels and glands generally, electricity in stimulating the vaso-motor centers and in storing the nervous batteries with the force which is like the nervous force, shock, massage, dry-cupping, exercise, and, above all, ergot, for its specific tonic effect on the circulation, especially on those vessels which are relaxed from lack of sufficient nervous impulse on them, or paralyzed from over-distension and incapable of contracting against this pressure from nervous impulse alone. While ergot contracts the unstriped muscular fiber it certainly acts on those fibers most which most need its aid; otherwise it would not tend to produce equilibrium of the circulation.

I have often observed, when applying galvanism over the cervical sympathetics, that the ears, face and neck, which before treatment were more or less suffused, gradually paled until no vestige of suffusion remained and sometimes pallor supervened. I have frequently produced the same disappearance of suffusion with ergot, but not pallor. The galvanism, stimulating the vaso-motor centers of the head, produced anemia of the vessels of that region if over-supplied; but the ergot produced only general equilibrium because it acts on all dilated vessels wherever they may be. The objection made to ergot, that it raises blood pressure, seems to me unfounded within the limit of rational dosage. If it raises blood pressure in the arteries it is diminished in the veins and capillaries, and when you have secured in any given case an ideal or approximate equilibrium of the circulation, what better result can you desire in that case? In one given case the general blood pressure may be much higher than in another given case, but in any given case, to demand something better than general equilibrium, a proper proportion in each part, seems as superfluous as to request the artist to improve the hue of the lily. Of course, normally, physiologically, there is disturbance of equilibrium of the circulation. Whatever organ or set of organs is now supreme in functional action is receiving more than its usual supply of blood and the rest have a diminished supply. Pathologic activity is quite another thing. If the circulation in the brain is not in good tone functional action is continuously excessive and not well performed. Thoughts are abundant, but not orderly. A confused mass of ideas comes before the perception and it is difficult or impossible to arrange them. If expressed, there is incoherence. Or, inflammation develops, exudation takes place and function ceases. If the circulation in the digestive tract is not in tone, secretion is abnormal in quantity or quality, or both, and the objects of its function are not obtained. If the circulation in a wounded part is not in tone repair is slow or does not occur, or inflammation supervenes with its serious or fatal consequences. All these conditions occur because

of lack of tone in the circulation. Ergot is the one powerful, effective therapeutic measure to secure both equilibrium and tone in the circulation, and this is surely "the great value of ergot in therapeutics" rather than "its action on the uterus." In this respect it has a thousand or ten thousand applications to one demand for it on the womb.

If you ask me how ergot produces its effect on the relaxed unstriped fibers, I must confess that I do not know. I have made no experiments on animals. Every new use which I have made of ergot in my practice was made on analogical reasoning on previous conditions and effects in other subjects. If, in a case of headache, I use galvanism over the cervical sympathetic ganglia, I relieve the headache by stimulating those nervous batteries to a greater activity, which creates more force, which is then distributed over their wires, the vaso-motor nerves, to the muscular tissue of the blood vessels, which then contract. If I give to the same patient with the same sort of headache a hypodermic of ergot, I also relieve the headache with more certainty and more promptly; but there are other effects of a more general character, all-over effects, that are not produced by the galvanism along the neck. Hands and feet become warm, glands are stimulated and their functions better performed; the pulse, if too full, becomes smaller and softer, if too small it becomes fuller; the heart action is slowed and irritability disappears, a general sense of comfort and well-being prevails, the whole system is normalized. I can hardly believe that all this is developed in the brief time solely by the action of ergot on the vaso-motor centers; and I do not hesitate to say that I believe that ergot acts directly from the circulation in which it is being carried. Even the improved activity of the nerve centers themselves may be due to the like correcting of their own blood vessels, for I am convinced that disturbed function in any organ is chiefly due to hyperemia, dilated blood vessels. However, the manner of action of ergot is not to be compared in importance with what it does, and of that I feel more competent to assert.

INSOMNIA.

Associated with many nervous affections, especially insanity and its ally neurasthenia, is insomnia, ordinarily one of the mose difficult conditions to meet therapeutically. I believe it is generally accepted that in natural sleep there is a diminished blood supply to the brain, which theory is in harmony with my observations of the action of ergot in insomnia. Ergot is not only the most effective agent in insomnia, but the sleep which follows its administration is the most natural sleep that is produced by any drug. I think this is because it produces most nearly the condition of the circulation which belongs with natural sleep. There is sometimes such irritability of the nervous tissues, as from organic changes, that it is desirable to associate with it some one of the more purely hypnotic class to dull the abnormal sensibility, which reminds me of an incident that occurred many years ago.

HEADACHE.

I was telling the late Dr. Hodge of Philadelphia, a famous obstetrician of his day, my treatment of a case of insanity which he had commended to my care. I said that I was giving her chloral and ergot to help her to sleep. With manifest sarcasm he inquired, "Do you call ergot an hypnotic, Doctor?" "No!" I replied, "I don't call it an hypnotic, but I do call it a mighty efficient aid to an hypnotic." It is probable that the doctor had never thought of ergot except as related to his specialty. Scores of times patients have fallen asleep in my office after having a hypodermic of ergot to relieve a headache. This also suggests the relation of sleep to a diminished blood supply to the head, for headaches are undoubtedly congestive in the large majority of instances. Indeed, I think an anemia headache very rare, and if I diagnosed such an one I might then give ergot, for there would likely be some part of the circulation hyperemic, the correcting of which would bring a fuller supply of blood to the head. Headache is probably the most common complaint of humanity, and in itself comprises an extensive field for the application of ergot, not only for immediate relief, but to give tone to the cerebral vessels that will prevent recurrences. Chronic and recurrent headaches can be cured by a course of ergot, though in such cases I prefer to use galvanism over the cervical sympathetics in conjunction with hypodermic injections of ergot.

EYE AND EAR DISORDERS.

A common associate symptom with chronic or recurrent headaches is a disordered function of sight, which often leads to the use of glasses, which are frequently changed because the varying conditions of the circulation produce varying states, not only of the retina, but of muscular action on lenses and in iris. In such cases headache is, I think, too frequently attributed to the eye condition, when both are more likely related to a common cause, disordered circulation. Such patients whom I have been treating with ergot to relieve the headache have often remarked on an improvement in vision and a greater comfort in the use of the eyes in sewing, reading, etc. Sometimes, also, a similar relief has occurred from deafness associated with chronic headache. I will relate a case which I treated in Philadelphia seventeen years ago.

A young woman had come to me from Connecticut with a history of eighteen months continuous headache, which, after a few weeks' treatment with ergot and galvanism, was permanently cured. She had a friend at Bryn Mawr, who also suffered from continuous headache, whom she commended to my treatment. This woman was so deaf that I had to yell my questions into her ear and then was not always understood. She never smiled, but had that serious, anxious and constrained expression characteristic of suffering and isolation. After treating her awhile I had noticed that I did not have to speak so loudly to her, but had not mentioned the fact. One day, about a fortnight after I began treatment, she came in smiling and jubilant and exclaimed, "Do you know, Doctor, I heard my sister play on the piano yesterday?" It then appeared that she was passionately fond of music, and her sister a fine pianist, but for more than three years she had not heard the tones of the piano. She had been treated three years by a celebrated ear specialist of Philadelphia without benefit and, during the same time, by a neurologist, also without relief. Later, she heard my conversation in ordinary tone and was free from headache between treatments. Because of my removal from Philadelphia I was obliged to discontinue my treatment of this case before complete recovery, but there had been such remarkable improvement within a few weeks, both as to headache and the deafness, that recovery seemed only a matter of further treatment.

I can not say all that I desire to say and relate illustrative cases; otherwise I would be glad to detail other cases of deafness in which ergot relieved by contracting blood vessels, and also to relate other eye cases as iritis, retinitis and optic atrophy, in which ergot or ergot and galvanism effected what eye specialists had not only not accomplished, but had declared could not be accomplished. The relief of pain in iritis has been astonish-

ingly prompt and lasting. I will be very glad if some ophthalmologist will give ergot a thorough trial in that painful, serious and so largely intractable affection, glaucoma; not simply as to the relief of pain, for I believe it will be found a valuable curative measure.

PAIN IN GENERAL.

For the relief of pain in general, from toothache to heartache, you will find ergot surprisingly effectual. The man who exclaimed, "Pain is the cry of a nerve for food!" may have recognized his obligation to poetic license, but, so far as it is figuratively true, it depends on a disordered state of the circulation as the cause of the nerve starvation. A more literally correct dictum as to causation of pain would be: "Pain is the cry of a nerve because big bellied blood vessels are squeezing it too harshly." When a sufficient dose of ergot has brought them to a proper respect for the space they should occupy in the economy the nerve will be comfortable and pain will have departed.

I can not help relating, in this connection, another case which later developed two new and important uses for ergot.

A confrère in my town related the case, seeking my advice as to treatment. He had been called to a young man who was suffering intensely from pain between the eyes. He could find no cause for it, and concluded it was neuralgic and gave morphia hypodermically, but without relief, and finally had to resort to anesthetics, as the fellow was frantic from the pain. I recalled the continuous mucous tract from the nose to the frontal sinuses, and thought the pain might be due to extreme congestion of that membrane in the narrow and confined tract, and advised ergot hypodermically should he have another attack. The doctor smiled incredulously, but, as he did not know what else to do, promised to try it. It was not long before another attack did occur, and when I next met the doctor he remarked, "Well, it was very queer, but the ergot did relieve him at once."

MORPHIN POISONING.

To those who have not used ergot broadly its effect in many cases will seem "very queer" until the rationale of its action is appreciated. I do not pretend to claim that my diagnosis in this case was correct, but I do claim that, in some way, that young man's pain depended on dilated blood vessels.

Later, this subject had another of his peculiar attacks, and his physician not being accessible, another was called, who had not heard the ergot story as related to this case and, as it was a matter of pain, he began giving morphia hypodermically, ineffectually and repeatedly until he had given three and a half grains, when its poisonous effects appeared and the patient was relieved of pain, also of perceptible pulse and pretty nearly of respiration. The family physician was then found, and sometime later I was sent for to bring my battery. I took with me a large Kidder coil and an extra cell. I found the patient on the floor, limp, cold, cyanosed, pulseless, even the heart action not discoverable, and respiration but two per minute. It was a long time before there was any evidence of sensation from even the full strength of the coil and a couple of hours before there was any demonstration of pain. At that time, when the application was suspended, he lapsed into the deep stupor from which no other means used to rouse him brought any response. While continuing to apply the faradism, the question occurred to me, "What is the cause of this universal paralysis?" which I expressed aloud, and, having no response, answered myself: "It must be the great vascular engorgement of the brain." With this thought came the idea of using ergot, which I immediately proposed, and this was assented to by the doctor who had given the morphia, but the family physician objected that, as the patient would die in any case, if we gave him a hypodermic the family would be sure we had killed him. I argued, but in vain. Fortunately the family physician soon after remembered an obstetric appointment, and as soon as he left I gave a hypodermic of ergot, with the result that in a brief time the patient, without other means being used to rouse him, sat up awake and clear and conversed with us and did not again relapse.

APPENDICITIS.
